the number of kilowatts connected on these respective dates being 34,445 and 30,009. On July 1st, 1908, in addition to the above connections, there were orders in hand for a further 1,357 kw. The gross revenue amounted to £143,006, being an increase of £1,693 over that of the first six months of 1907. The net revenue for the half-year was £76,678, to which is added £20,473 brought forward. The number of units sold during the half-year was 12,430,827, as compared with 11,856,427 during the corresponding period of 1907, showing an increase of 574,400 units, chiefly in the supply for power purposes, the lighting supply having been adversely affected by the bright weather experienced in the second quarter of the year. Dealing with the power Bills before Parliament, the report states that numerous amendments have been made in the companies' Bills as originally deposited, and, the Committee having decided to allow all three Bills to proceed as modified, they have been passed by the House of Lords, and will in due course be introduced into the House of Commons. It is to be hoped that a final settlement, satisfactory to all parties, may be arrived at during the present session of Parliament so as to put an end to the heavy expenditure and work thrown on the London companies during the past few years in connection with Parliamentary proceedings. The directors have declared the following dividends, less income tax, viz., 6s. per share on the company's preference shares, 5s. per share on the company's ordinary shares.

DIRECT UNITED STATES CABLE CO.—At the annual general meeting on Wednesday last week, the report and accounts, given in our last issue, were adopted. The chairman, Mr. E. M. Underdown, K.C., said that the revenue had fallen by £5,688 compared with the corresponding period of 1907, when the great activity that characterised the Atlantic business for some time was already beginning to slacken. This was followed by serious financial difficulties in America, the effects of which were still apparent. With regard to the damage done to cables by trawler vessels off the coast of Ireland, he did not think much injury had been done to the company's cables, but the matter was, nevertheless, of much importance to them. The Inter-Departmental Committee appointed by the Postmaster-General was now considering the matter, and there was no doubt that measures would be taken as far as practicable to secure their cables from damage in this way.

DUBLIN UNITED TRAMWAYS.—The half-yearly meeting was held last week in Dublin, when the report and accounts, given in our last issue, were adopted. The Chairman, Mr. W. M. Murphy, said that the half-year, owing to the International Exhibition, was one of exceptional prosperity for the tramway company. The falling off of passengers' receipts amounted to £3,115, compared with the corresponding half-year of 1907, which included the first two months of the exhibition traffic last year. Compared, however, with the receipts of the first half-year of 1906, there was the substantial addition of £5,043, from which it would be seen that the continuous increase under normal conditions in the gross earning powers of the tramways showed no signs of exhaustion. For the first time there was a check to the expansion of the parcel traffic, which showed the small falling off of £29, but this was also attributable to the fact that some of the parcel traffic last year was due to the exhibition. The general expenses had increased by £2,849, more than half of which was due to the increased generating expenses, owing to the high price of coal. The increase of £378 in general charges was accounted for by the expenses they had been compelled to incur in protecting the company's interests in Parliament in relation to the Central Ireland Electric Power Bill. Out of the large profits made in the second half of 1907, they were enabled to appropriate £10,000 towards the reconstruction of the Southern District Tramways between Blackrock and Ailesbury Road. On that work a sum of £5,250 was expended during the past half-year, and there remained on June 30th a balance of £4,749 towards its completion, which was estimated to cost about £14,000. When that work was finished they would have an entirely new tramway between Haddington Road and Temple Hill, Blackrock. They had already appropriated to the reconstruction of that line, all out of current revenue, the large sum of £20,500. It would be desirable before long that they should put their capital account in order, and the directors were considering the best way of raising a comparatively small amount of additional capital during the current half-year.

EAST LONDON RAILWAY CO.—The half-yearly meeting was held on Wednesday last week, Lord Claud Hamilton presiding. With regard to the question of electrification, referred to in the directors' report (given in our issue of July 23rd), the chairman stated that the report by Messrs. Jones and Firth, the electrical engineers to the Metropolitan and Great Eastern Railway Companies respectively, had been referred to the general managers of the six lessee companies for detailed consideration. The matter was a very difficult one, but the spirit in which it had been taken up by the lessee companies was encouraging. With regard to the cost, he stated that the total equipment of the line, including entrance into Liverpool Street and New Cross stations, and the supply of electrical energy, came out under one scheme at £59,600, and under an alternative scheme at £79,600. A further report was in the course of preparation giving an estimated cost without entrance into Liverpool Street station, as the officers of the Great Eastern Railway were of the opinion that it might jeopardise the safety of the public and the servants of the company to work electric trains over the very complicated and intricate system of permanent way leading into Liverpool Street.

ELECTRIC & GENERAL INVESTMENTS CO.—At the annual meeting on Wednesday last week, the report and accounts given in our issue of July 23rd were adopted. Mr. J. B. Braithwaite, the chairman, who presided, remarked that the business of the Company was a financial one specially connected with electrical investments, but as the past year had been one in which little or no finance of that character had taken place, the opportunities for carrying on a profitable business had been greatly curtailed, and they had had to rely almost entirely on their income from investments.

GREAT NORTHERN & CITY RAILWAY CO.—The directors' report shows that the total revenue receipts for the six months ending June 30th last amounted to £46,476, and the cost of working to £23,286, being at the rate of 50·10 per cent. Inclusive of the balance brought forward from December 31st last, and after providing for interest on debenture stock and other charges, and setting aside £500 to renewal fund, there remains a balance of £419, which your directors recommend be carried forward to next account. The number of passengers for the six months under review, including season ticket holders, was 6,875,602, as against 8,269,455 for the corresponding period last year. The heavy falling off in the number of passengers is attributable to the increasing competition of the London County Council's electrified tramways, by which the company is seriously affected.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The report for the half-year ending June 30th, 1908, states that the Bill promoted by the company, which was approved by the shareholders at the last half-yearly meeting, has passed into law, and under the provisions thereof 35,704 ordinary shares have been converted into preference shares as on and from July 1st, 1908, entitled, out of the profits of the company in each half-year, to a fixed preferential dividend at the rate of 4 per cent. per annum guaranteed by the Underground Electric Railways Co. of London, Ltd. The gross receipts amounted to £147,763, being an increase of £41,193, or 38·65 per cent., on the receipts for the corresponding half of 1970. The working expenses amount to £74,980, being a decrease of £810, or 1·07 per cent. After providing for interest and rents and for dividend at the rate of 4 per cent. per annum on the preference shares, there remains a balance of £22,475 available for dividend on the ordinary shares, and the directors recommend that a dividend at the rate of ¾ per cent. per annum be declared on the amount paid up on the ordinary shares, leaving a balance of £4,886 14s. 9d. to be carried to next half-year's account. The number of passengers carried was 17,446,477, an increase of 5,492,718 over the corresponding period of 1907. The meeting is on August 11th.

LANCASHIRE & YORKSHIRE RAILWAY CO.—The gross revenue for the June half-year shows a decrease of £57,152 and the gross working expenses an increase of £33,960, resulting in a balance on revenue account of £1,068,449, as compared with £1,159,561 in the corresponding half-year. There is an increase of £5,338 in the charges for interest on loans and debenture stock, £2,658 of which is caused by the conversion of the West Lancashire Railway debenture interest stock into Lancashire and Yorkshire debenture stock, in accordance with the provisions of the Act of Parliament of 1897, with a consequent decrease of that amount in the West Lancashire rent charge, and an increase of £6,418 in general interest and bankers' interest. The net revenue balance available for distribution is £785,020, as compared with £877,432 in the corresponding half-year. The balance, after meeting the charge for interest on guaranteed and preference stocks, amounts to £304,225, which is available for dividend on the ordinary stock, out of which the directors recommend a dividend of 3 per cent. per annum, and to carry forward a balance of £22,133 to the next account, as against 4 per cent. per annum for the corresponding period with a balance forward of £21,679. The amount of capital expended during the half-year for general purposes has been £201,292 against £235,907 authorised by the shareholders at the last half-yearly meeting. At the ensuing meeting the directors will ask for authority to expend £177,922 on capital account for general purposes during the current half-year. The reduction in net revenue available for dividend has been entirely brought about by the very unsatisfactory state of trade. Commencing in January last, the fall in imports and exports throughout the country has been month by month very considerable; in addition to which, notwithstanding that every effort has been made in the direction of economy, the expenses show an increase, largely under the head of coal, but there will be some relief so far as this item of expenditure is concerned during the current half-year. At the meeting yesterday the report and accounts were adopted.

LANCASHIRE ELECTRIC POWER CO.—A special meeting was held in London on Wednesday last week to confirm the

Digitized by Google

resolution passed at the ordinary general meeting, appointing Mr. H. F. Parshall chairman of the company at a salary of £1,000 per annum, and a commission of 10 per cent. on all profits above £20,000, calculated before charging interest on the debenture stock and income bonds, and also appointing as directors Sir R. A. Hampson, Mr. J. Young, and Mr. J. L. Rushton. The resolution also increased the capital of the company by the creation of income bonds for £100,000. The resolution was carried.

LIVERPOOL OVERHEAD RAILWAY CO.—The report for the half-year to June 30th, 1908, shows gross revenue receipts amounting to £37,868, and working expenses to £30,511. The number of passengers carried during the half-year was 5,367,286, compared with 5,423,595 in the corresponding half-year of 1907. The falling off in the traffic is attributed to the shrinkage in trade and the considerable number of steamers laid up. After deducting interest on mortgage debentures, and on calls paid in advance, viz., 4,329, there remain, with the balance brought forward from December 31st, 1907, the sum of £7,206 available for dividend. Out of this balance the directors recommend a dividend of 5 per cent. per annum on the (1892) preference shares (less income tax), leaving a balance of £4,206 16s. 9d. to be carried forward to next half-year. The meeting is on the 11th inst.

METROPOLITAN DISTRICT RAILWAY CO.—The report for the half-year ended June 30th, 1908, states that the expenditure on capital account during the half-year has been £59,499. The gross receipts amount to £247,900, being an increase of £27,272 on the receipts for the corresponding half of 1907. The working expenses amount to £154,829, being an increase of £10,893. After providing for rent charges, interest on debenture stock, and other charges, the net revenue account shows a deficit of £8,951. To this deficit must be added the sum of £10,937, being the company's proportion of net revenue arising from the City lines joint undertaking, which, although included in the net revenue account, is not available for payment of debenture interest, being specially appropriated to the payment of dividend on the 4 per cent. guaranteed stock. With the above-mentioned addition, the deficiency for the half-year chargeable to capital under the company's statutory powers is £19,889, as compared with £28,191 in the corresponding half of 1907. The dividend payable on the 4 per cent. guaranteed stock is at the rate of £1 15s. per cent. per annum. The number of passengers carried during the half year was 29,626,586, an increase of 4,199,761 over the corresponding period of 1907. The bill, which was approved at the last half-yearly meeting, has now become law. It is proposed to issue £550,000 of the authorised £750,000 prior lien debenture stock during the current half-year, bearing interest at the rate of 4 per cent. per annum, and redeemable at the price of 105 per cent. on or at any time after December 31st, 1920, and, out of the proceeds of the issue, the existing charges on the company's surplus lands, amounting to £478,175, will be paid off. The meeting is on the 12th inst.

METROPOLITAN RAILWAY CO.—At the half-yearly meeting on Thursday, the report and accounts given in our last issue were adopted. Sir Charles McLaren, Bart., M.P., who presided, said that there had been a very large diminution in receipts from first-class passengers, which, however, had been more than made good by the satisfactory increase in the third-class traffic. They had again suffered from the effects of omnibus, tube, and tramway competition, but he was happy to say that as far as the two former were concerned, the directors believed they had now reached the period when the maximum loss from that competition had been ascertained. A satisfactory feature of the half-year's working was that the average receipts per passenger had increased from 1·599d. to 1·465d. At present they were carrying a large number of passengers at fares which were not remunerative, but they had been forced to do this by the action of their competitors.

Royal Assent.—Royal assent was given to the following, amongst other Bills, on Saturday:—Telegraph (Construction) Act; Ayr Corporation Tramways Order Confirmation Act; Electric Lighting Orders Confirmation (No. 1) Act; Electric Lighting Order Confirmation (No. 2) Act; Electric Lighting Order Confirmation (No. 3) Act; Lanarkshire Tramways Order Confirmation Act; Paisley District Tramways Order Confirmation Act; Tramways Order Confirmation (No. 2) Act; North-East London Railway Act; King's College London (Transfer) Act; Bristol Tramways Act; Leicester Corporation Act; Doncaster Corporation Act; Metropolitan District Railway Act; Leeds Corporation Act; South Wales Electrical Power Distribution Co. Act; Wishaw Burgh Electricity, &c., Act; Wolverhampton Corporation Act; Finchley Urban District Council Act; London County Council (Tramways and Improvements) Act; Macclesfield and District Tramways (Abandonment) Act; Metropolitan Electric Tramways Act; Blackburn Corporation Act; Keighley Corporation Act; Gt. Northern, Piccadilly, & Brompton Railway Act; London United Tramways Act; Nottinghamshire and Derbyshire Tramways Act; Central Ireland Electric Power Act; Ravensthorpe Urban District Council Act.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire-bars, net c.i.f. port of arrival, quoted on Tuesday night, was £61 5s. to £61 15s. per ton (last week, £60 10s. to £61 per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Dolter Electric Traction, Ltd., is to be wound up voluntarily. Mr. W. S. Ogle, 90 Cannon Street, London, is liquidator.

COMPANY MORTGAGES, &c.

ICAN DIRECT TELEGRAPH CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date, and not required to be registered under Section 14 of the Companies Act, 1900, has been filed pursuaant to Section 12 of the Companies Act, 1907. Particulars—Debentures, dated February 23rd, and March 22nd, 1895, on which £28,200 is outstanding.

ANGLO-ARGENTINE TRAMWAYS CO.—A statement of the total amount outstanding on July 1st, in respect of mortgages and charges created prior to the date and not required to be registered under Section 14 of the Companies Act, 1900, has been filed pursuant to Section 12 of the Companies Act, 1907. Particulars—Indenture dated August 13th, 1888, securing £266,600 debenture stock, charged on company's concessions, tramways, stations, and property.

CENTRAL ELECTRIC SUPPLY CO.—A charge under the Land Transfer Acts, 1875 to 1897, dated June 15th, 1908, to secure £50,000 further stock and a premium of £5,000 thereon (supplemental to a trust deed, dated July 2nd, 1901, securing £250,000), has been registered. Property charged—Certain land in Marylebone. Trustees—Right Hon. A. Lyttelton, K.C., 3 Paper Buildings, Temple, E.C., and William Hayes Fisher, 13 Buckingham Palace Gardens, S.W.

A. C. COSSOR.—Particulars of £3,500 debentures, created by resolution of July 9th, 1908, have been filed pursuant to Section 10 (3) of the Companaies Act, 1907. Property charged—The company's assets, present and future, including uncalled capital. There are no trustees.

NAIROBI ELECTRIC POWER & LIGHTING CO.—Particulars have been filed of £4,000 6 per cent first mortgage debentures created by a resolution on April 8th, 1908. Property charged The company's undertaking and property, present and future, including uncalled capital, but excluding £1,500 deposited in the joint names of the Crown Agents for the Colonies with the National Bank of India, Ltd.; capital uncalled on 10,000 preference and 6,000 ordinary shares, and a contract, dated July 20th, 1906, and all interest therein and power conferred thereby, save so far as the company shall hereafter, with the consent of H.M. Commissioners for the East Africa Protectorate, subject the same to such charge. No trustees. An issue of £600 debentures, part of above series, has also been registered.

ORIENTAL TELEPHONE & ELECTRIC CO.—A memorandum of satisfaction has been filed to the extent of £1,545 of a trust deed dated June 28th, 1905, securing £100,000 debenture stock.

SANDYCROFT FOUNDRY CO.—Particulars have been filed of £20,000 6 per cent. debentures created by a resolution on April 16th, 1908. Property charged, the company's undertaking, present and future, including uncalled capital. There are no trustees.

UNITY MOTOR ELECTRICAL & GENERAL ENGINEERING CO.—Particulars of £1,000 5 per cent. debentures, created by resolution of July 4th, 1908, have been filed pursuant to Section 10 (3) of the Companies Act, 1907. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees. Issue on same date of £325 debentures, part of above series, also registered.

VICKERS SONS & MAXIM.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under Section 14 of the Companies Act, 1900, has been filed pursuant to Section 12 of the Companies Act, 1907. Particulars—Trust deed, dated November 16th, 1897, securing £1,250,000 debenture stock, charged on freeholds, leaseholds, and other assets of the company, including uncalled capital.

Congress on Electrical Units and Standards.—The President of the Board of Trade has appointed the Lord Rayleigh, P.C., O.M., Professor J. J. Thomson, F.R.S., Dr. R. T. Glazebrook, F.R.S., Sir John Gavey, K.C.B., and Mr. A. P. Trotter to be the British Delegates to the International Conference on Electrical Units and Standards which is to assemble in London on October 12th. Mr. W. Duddell, F.R.S., and Mr. M. J. Collins (Board of Trade) will act as Secretaries to the British Delegates, and Mr. F. E. Smith and Mr. C. W. S. Crawley as Assistant Secretaries. We gave particulars of the objects and scope of the Congress in ELECTRICAL ENGINEERING, Vol. III., p. 894.

NEW COMPANIES

BALCHIN, SCHULZ & CO.—This company was registered on July 13th, with a capital of £10,000 in £1 shares (7,500 5 per cent. cumulative preference), to adopt an agreement between H. A. Balchin, G. F. Schulz, and C. H. Hayward of the first part, H. A. Woodman and F. Coomber of the second part, and the company of the third part, for the acquisition of the businesses (1) carried on by the said H A. Balchin, G. F. Schulz, and C. H. Hayward as "Balchin, Schulz, and Co.," at Lennox House, Norfolk Street, W.C., and (2) carried on by the said H. A. Woodman and F. Coomber, as "Armitage & Co.," at 27a Gloucester Street, Queen Square, W.C., and to carry on the business of electrical and mechanical engineers, founders, manufacturers of agricultural implements and other machinery, &c. The subscribers are: H. A. Balchin, G. F. Schulz, C. H. Hayward, H. A. Woodman, and F. Coomber. Private company. The number of directors is not to be less than three, nor more than seven; the first are H. A. Balchin, G. F. Schulz, C. H. Hayward, H. A. Woodman, and E. Coomber (all permanent, subject to holding 200 shares each). Qualification of ordinary directors, 100 shares. Registered office, Lennox House, Norfolk Street, Strand, W.C.

DEY TIME REGISTERS.—This company was registered on July 13th, with a capital of £50,000 in £1 shares (15,000 6 per cent. cumulative preference), to take over the business carried on at Liverpool, London, Glasgow, Paris, Brussels, or elsewhere, as patentees, inventors, and manufacturers of and dealers in time recorders, tell-tale and other clocks and watches, time stamps, horological instruments, slips, sheets, cards, discs, crates, boxes, and cases, and other articles and mechanism, as "Howard Bros.," and to adopt an agreement with F. M. Howard, W. R. Howard, E. S. Howard, and W. T. Jolliffe, and to carry on the said business and that of electrical engineers and contractors, suppliers of electricity, synchronisers of clocks and timepieces, manufacturers of and dealers in railway, tramway, electric, magnetic, galvanic, and other apparatus, &c. The subscribers are: F. M. Howard, W. R. Howard, E. S. Howard, and W. T. Jolliffe. Private company The number of directors is not to be less than three, nor more than seven; the first are: F. M. Howard and E. S. Howard (joint managing directors), and W. R. Howard (all permanent, subject to holding 1,000 shares). Qualification of ordinary directors, 100 shares. Remuneration of joint managing directors, £500 each per annum, and 5 per cent. of the surplus profits in excess of £6,000; of the other directors, £200 per annum. Registered offices, 40 Paradise Street, Liverpool.

ELECTRICAL REGULATORS & ECONOMISERS.—This company was registered on July 13th, with a capital of £2,000 in £1 shares, to acquire and turn to account certain patent rights granted or to be granted to H. S. Martin, of Liverpool, relating to improvements in electric resistance, to make experiments in and exhibitions of applied electricity, magnetism, or similar agencies, &c. The subscribers are: C. T. Wood, E. H. W Butterworth, R. M. Grierson, and H. S. Martin. Private company. Table "A" mainly applies. Registered office, 51 North John Street, Liverpool.

PARIS ACCUMULATOR CO.—This company was registered on July 14th with a capital of £3,000 in £1 shares to acquire the business of an accumulator manufacturer and assembler, carried on by S. Leuchters, trading as the "Paris Accumulator Co." at 14 Park Cross Street, Leeds, and to carry on the same and the business of manufacturers in motor-cabs, motor-cycles, &c. Private company with two subscribers, viz., S. Leuchters, 14 Park Cross Street, Leeds, accumulator expert; and W. Wainwright, 61 Lodge Lane, Beeston Hill, Leeds, pork butcher, each signing for one share. The first directors are S. Leuchters (permanent managing director and chairman) and W. Wainwright. Qualification, 100 shares. Remuneration of S. Leuchters, £250 per annum. Table "A" mainly applies. Registered office, 14 Park Cross Street, Leeds.

URUGUAY EAST COAST RAILWAY CO.—This company was registered on July 14th, with a capital of £125,000 in £1 shares, to acquire from the Government of the Republic of Uruguay a concession for working an existing line of railway from Olmos Junction to La Sierra, and for constructing, equipping, and working extensions thereof from La Sierra to Maldonada, and to Rocha and elsewhere, and to adopt an agreement with the Uruguay Great Eastern Railway Co., Ltd. The subscribers are: G. Grinnell-Milne, G. Hannaford, A. L. Secretan, F. A. Kentfield, R. A. Woirley, T. Merrylees, A. Frewin. The number of directors is not to be less than three, nor more than six; the first are G. Grinnell-Milne (representing the holders of first charge debentures), G. Hannaford (representing holders of income debenture stock), and A. Frewin (representing the shareholders). Qualification of director representing shareholders, 400 shares. Remuneration, £2,000 per annum, dividend. The directors shall, in accordance with the said agreement, create a series of 5 per cent. first charge debentures not exceeding in the first instance £315,000 in nominal value, which limit may be increased by £5,000 for every kilometre of railway hereafter constructed under the new concession referred to in the said agreement in excess of 63 kilometres, and shall also create £184,900 income debenture stock with interest at 4 per cent. payable during the first three years from issue only out of the net revenue of the company. Registered office, Salisbury House, London Wall, E.C.

MISCELLANEOUS CITY NOTES

ARMSTRONG, WHITWORTH & CO.—An extraordinary general meeting has been called for the 7th inst., at Newcastle, for the purpose of considering, and, if thought fit, passing a resolution authorising the raising or borrowing at interest, for the purposes of the company, a sum not exceeding £1,000,000.

BAKER STREET & WATERLOO RAILWAY CO.—A dividend of 4 per cent. per annum is recommended upon the preference shares and ¾ per cent. per annum on the ordinary shares. The holders of ordinary shares other than the Underground Co. will receive an additional dividend of 2¼ per cent. per annum (making 3 per cent. per annum in all) out of moneys payable by the Underground Electric Railways Co. of London under the guarantee agreement.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—Subject to final audit the accounts for the June half-year show net revenue sufficient to pay interest on the total authorised debenture stock. The carry forward is £832.

CHARING CROSS, WEST END, & CITY ELECTRICITY SUPPLY CO.—The directors have declared an interim dividend at the rate of 5 per cent. per annum on the ordinary shares of the West End undertaking, and increased the carry forward in the case of the West End undertaking to £4,748, and in the case of the City undertaking to £4,591. The figures for the half-year ended June 30th, 1908, as compared with the corresponding period of last year (excluding the bulk supply from one undertaking to the other) are:—

West End: Units sold (1907) 5,098,880, (1908) 5,509,773; Revenue (1907) £65,093, (1908) £68,237. *City:* Units sold (1907) 4,234,589, (1908) 4,792,333; Revenue (1907) £46,372, (1908) £50,114.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The directors recommend the payment of interest at the rate of 4 per cent. per annum on 35,704 shares, which have been converted from ordinary into preference shares, in addition to a dividend of ¾ per cent. per annum on the ordinary share capital. The carry forward is £4,886.

W. T. HENLEY'S TELEGRAPH WORKS CO.—An interim dividend of 10 per cent. per annum for the half-year to June 30th has been declared upon the ordinary shares.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING CO.—A dividend of 8 per cent. per annum (4s. per share) less income tax has been declared upon the ordinary shares for the last half-year.

LIVERPOOL DISTRICT LIGHTING CO.—An interim dividend at the rate of 5 per cent. per annum for the June half-year is recommended.

METROPOLITAN ELECTRIC SUPPLY CO.—An interim dividend of 5 per cent. per annum (2s. 6d. per share) has been declared upon the ordinary shares for the past half-year.

METROPOLITAN DISTRICT RAILWAY CO.—A dividend on the 4 per cent. guaranteed stock for the past six months has been recommended at the rate of 1¾ per cent. per annum.

THOMAS PARKER.—An extraordinary general meeting was held in Wolverhampton on Wednesday last, when the following resolution was passed and confirmed at a subsequent extraordinary general meeting:—"That it is desirable to make further provision for the reconstruction of the company, and accordingly that the draft agreement submitted to this meeting and expressed to be made between the company and its liquidator of the one part, and the proposed new or reconstructed company, namely, the Rees Roturbo Manufacturing Co., Ltd., of the other part, whereby provision is made for the transfer of the undertaking of this company to such new company on the terms therein set forth, and the draft Memorandum and Articles of Association of such proposed new company also submitted to this meeting, be and the same are hereby respectively approved; and that this company be wound up voluntarily, and that Mr. William Arthur Nelson, Incorporated Accountant, of Lich Gate, Wolverhampton, be and he is hereby appointed liquidator thereof, and that such liquidater be and he is hereby authorised and empowered to enter into an agreement with the new company, when formed, in the terms of the said draft and to carry such agreement into effect with such, if any, modifications as he may think fit to assent to, and that for the purposes aforesaid the said liquidator may exercise all or any of the powers, authorities, and discretions capable of being conferred on him under sections 160 and 161 of the Companies Act, 1862."

WALSALL ELECTRICAL CO. In the Chancery Division last week, Mr. Justice Swinfen Eady sanctioned the reduction of the capital of this company by £4,380.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—An interim dividend for the June half-year at the rate of 10 per cent. per annum, less tax, is recommended.

Latest Time for Receiving

Letters for Insertion, *Tuesday first post.*

Small Advertisements and Official Announcements, *Wednesday noon.*

Displayed Advertisements, *Tuesday first post.*

Corrections in Standing Advertisements, *Monday first post.*

All letters to be addressed to "Electrical Engineering," at the Editorial and Publishing Offices: 203-206, Temple Chambers, London, E.C.

Telegrams: "Circling, London." Telephone No.: 5509 Holborn.

Cheques to be made payable to The Kilowatt Publishing Co., Ltd., and to be crossed London and Westminster Bank (Temple Bar Branch).

Binding Cases for Vol. III. may now be ordered, price 2s. each, post free 2s. 4d. Readers can have their volumes bound by their own bookseller; or they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

SUMMARY

A strike of about 100 boiler-hands took place at the works of the Paris electricity supply companies, at eight o'clock last Thursday, causing an interruption of the supply for about 70 minutes, after which the men resumed work (Page 238.)

An inquest was held on Tuesday into the death of a boy, five years old, who had strayed on to the Metropolitan Railway line near Notting Hill, and was found with his wrist upon the positive rail, and his body upon the running rail. (Page 238.)

A single-phase goods locomotive has recently been taken into use on the Windsor, Essex and Lake Shore Railway in Canada. (Page 238.)

The following books are reviewed in this issue:—"Radio-telegraphy," by C. C. F. Monckton; "Electrometallurgy," by J. B. C. Kershaw; "Elementary Manual on Mechanics," by A. Jamieson; "Switchboard Measuring Instruments for Continuous and Polyphase Systems," by J. C. Connan; "The Deinhardt-Schloman Series of Technical Dictionaries in Six Languages, Vol. III."; "The Calculus for Engineers and Physicists," by R. H. Smith; "First Stage Steam," by J. W. Hayward; "Telephones, Their Construction, Installation, Wiring, Operation, and Maintenance," by W. H. Ratcliffe and H. C. Cushing; "Electric Bells and All About Them," by S. R. Bottone; "Questions and Answers in Electrical Engineering," by A. E. Moore and F. Shaw; "The Electron." (Page 239.)

An illustrated article on the functions of flywheels in electrical generating plants shows that flywheels are used to reduce variations in speed arising from uneven turning movement in prime movers, and rapid fluctuations of the external load, and to improve the parallel running of alternators by preventing correspondence between the free oscillation period of the alternators, and the cyclic irregularity of turning movement of the engines, which would set up resonance. The quantitative elements required for practical design are given. The applications of flywheels to converting sets, and to winding and rolling machinery are briefly discussed. (Page 241.)

An article by E. Goolding deals with the question of rail creeping, more particularly as regards the conductor rail on electric railways. The results of a series of observations on the North-Eastern Railway are given, and the influence of a number of causes is discussed. (Page 244.)

An article by Mr. L. H. Walter considers the relative merits of a number of systems of wireless telephony, which have been suggested and used, both as regards the methods of arranging the microphone in the sending apparatus to control the oscillations, and

Digitized by Google

the most suitable forms of detector for this class of work. (Page 247.)

The Locarno-Bignasco railway in the Maggia Valley, Switzerland, is of interest as one of the latest examples of Swiss single-phase lines. The overhead conductor is supplied at 5,000 volts over most of the line, but a pressure of 800 volts is used in the urban sections. The cars are provided with two independent collectors. That for the high-voltage system is of the Oerlikon curved bar pattern, while a bow collector is in use on the 800-volt sections. The motor coaches are each equipped with four 40-h.p. motors of the Oerlikon single-phase commutator type, supplied in the usual way with auto-transformers, of which two are carried on each car. (Page 249.)

An electrical equipment which replaces steam driving is at work in the Rubislaw granite quarries near Aberdeen. Current is taken from the mains of the Aberdeen Corporation and the applications of electrical power include ten cranes, a system of aërial ropeways, pumps, air-compressors, and the driving of stone-breaking, crushing and screening plant. (Page 251.)

The reports of H.M. Inspectors of Mines for the various districts contain a good deal of information regarding the use of electricity in mines. In addition to the comparative statistics as to the use of electric and other coal-cutting machinery, which we have already summarised, accounts are given of all the principal accidents attributed during the year under review to electrical causes, both fatal and non-fatal. It is pointed out how many of these could have been avoided by a closer observance of the Home Office special rules regarding electricity in mines. (Page 253.)

Among the papers read at the recent meeting of the Institution of Mechanical Engineers at Bristol was one by Mr. S. O. Cowper-Coles in which, after a short historical introduction, he described the centrifugal electrolytic process for the direct production of copper tubes, sheets and wire. (Page 255.)

The Ottawa branch of the Royal Mint has a very complete and modern system of electric driving. Rolling mills, cutting machines, and coining presses are geared direct to motors and the smaller machines are driven in groups from shafting. The Mint has its own sub-station, in which the two-phase alternating current supplied is transformed into low-pressure alternating for the lighting events and into continuous current for the power circuits. (Page 256.)

Under Electrometallurgy and Electrochemistry attention is drawn to the recent advances in electrochemistry as applied to metal depositions. One of the great difficulties met with has been, especially in the case of gold plating, the corrosion of the anodes. Anodes of carborundum are now suggested, and it is stated that they are practically unacted upon when employed even in such corrosive electrolytes as strong hydrochloric acid. (Page 257.)

Under Electrical Science, in the British and American Section, are notes on a new form of selenium cell and on a battery designed to yield very constant small currents. In the papers abstracted in the Continental Section, Tissot replies to Branly's criticism of his thermoelectric detectors; Gripenberg gives instructions how to deposit selenium by sublimation; and Almy investigates sparking potentials in microscopic spark gaps. (Page 258.)

The patents published last week, of which we give abstracts on a later page, include two relating to conduit systems of house wiring. The Auer Company patent the use of wire made of nickel and copper, either mechanically combined or in an alloy, for the leading-in wires of tungsten lamps. A new arrangement of field switch connections is described by the British Thomson-Houston Co., in which the field and adjustable resistance is first connected as a shunt to the field itself and then as a shunt to a fixed resistance in series with the field, and Siemens Brothers Dynamo Works have patented a speed controlling device for hoisting motors which releases a check brake when too high a speed is reached. Siemens & Halske patent the use of silicon in higher proportions than 1 per cent. for hardening tantalum without materially impairing the ductility of the latter metal, and Hermann Aron has a very broad patent for a multiple maximum demand indicator combined with a multiple tariff meter. A specification by the British Thomson-Houston Co. deals with the neutralisation of the inductive action on telephone and telegraph wires on single-phase railways. (Page 258.)

An agreement has been come to with the Admiralty by the Aberdeen Corporation for a supply of electrical energy to the proposed wireless telegraph station at Stoneywood, the terms being £350 per annum for five years, plus 3½d. per unit.—The agreement with the London, Brighton and South Coast Railway for a supply to their Brighton works was confirmed at the last meeting of the Corporation.—There was a gross revenue of £115,318 upon the Glasgow Corporation tramways for the year to May 31st. The net balance, after deducting capital charges, is £51,061. No less than £50,000 has been writen off for depreciation.—A deputation from the Manchester Tramways Committee is to visit the Continent to investigate the possibilities of trolley omnibuses for the outlying districts. During the past twelve months the sum of £15,000 was paid by the Manchester Tramways Committee as compensation for tramway accidents.—The "rateable value" basis of charging for electric supply has been adopted at Nuneaton.—An application has been made to the Oxford Corporation by the Electric Vehicles Development Co. for permission to run electric omnibuses.—The Salford tramway accounts for the year to March 31st show a gross profit of £96,761. The contribution in aid of the rates amounts to £18,000.—The first portion of the overhead trolley line erected in place of the Dolter surface contact system between Rawmarsh and Mexborough, has been opened for traffic.—A new 1,000-h.p. set has been added at the Leith electricity works. (Page 261.)

Extensions to the Aberdeen Electricity Works are to be carried out at a cost of £16,000.—Local Government Board inquiries have been held at Derby (£7,500), St. Anne's-on-Sea (£3,500), Southampton (£3,000), and Whitehaven (£1,700).—The London County Council require low-tension cables, high- and low-tension switchgear, and six 500-kw. and one 150-kw. motor generators.—A surface-condensing plant is required at Reigate. (Pages 264–266.)

At the half-yearly meeting of the Baker Street and Waterloo Railway Co., on Monday, Sir George Gibb made special reference to the exchange of passengers between London tube railways, and stated that in co-operation of working lay the best hope for the prosperity of urban railways.—Sir Henry Oakley, presiding at the half-yearly meeting of the Central London Railway on Thursday, mentioned that during the first six weeks of the Franco-British Exhibition they had carried 676,000 more passengers than in the corresponding period of last year.—The report of Edmundsons Electricity Corporation for the year ended March 31st, 1908, shows a net profit of £2,610, which is increased to £20,417 with the balance brought forward from the previous year. Mr. P. D. Tuckett, the chairman of the company, at the meeting on Thursday, said that the reduction in trading profits was accounted for by a smaller turnover and by the fact that the local authority losses had been charged against profit instead of reserve as formerly.—At the meetings of the Great Northern & City Railway Co. and the North London Railway Co., complaints were made of the effect of tramway competition. (Pages 267–269.)

The annual reports of H.M. Inspectors of Mines, extracts from which we publish on a later page, throw interesting light on the conditions under which electrical working is carried on. In a previous issue we gave some statistics regarding the use of electrical coal cutting machinery, and our article this week relates to investigations of accidents connected in one way or another with the electrical plant generally. One cannot help being struck with the small number of such accidents, considering the extent of the applications of electricity in mining, but examining the circumstances from another point of view, it is apparent that a large proportion of the comparatively few accidents that did occur would have been prevented by a closer observance of the special rules of the Home Office issued for this particular purpose. That these rules are valuable in preventing risks that might otherwise be present, is vouched for by more than one inspector. On the other hand, pure carelessness has been responsible for a number of accidents, while there have also been some cases in which what might at first sight appear to be carelessness might more accurately be ascribed to ignorance of the danger caused by lack of familiarity with the application of electricity. Improvement may be anticipated in this direction, however, for one inspector emphasises how quickly persons in charge of electrical machinery have been able to grasp its details and its dangers, and have learned to handle it with absolute safety. Taken all round the record is highly creditable, and when reading the collected accounts of such few electrical accidents which have occurred in the hundreds of collieries where electricity plays a part, one must not forget the other side of the account—namely, the number of cases in which possible risk of accident has been avoided by these improved methods of working.

It is to be hoped that one result of the closer *entente cordiale* between Great Britain and France may be the realisation, by our friends on the other side of the Channel, of the true difference between effective organisation and organised officialism. An example of the difference is afforded by the failure of the electric light over a large part of Paris for over an hour last Thursday. The new company that has taken over the concessions of the Paris electricity supply companies, and has been granted an extension of the monopoly, has had to pay a high price for these favours—so high a price, in fact, that the cost of electricity in Paris is destined to remain for many years far higher than the cost in London. A long and complicated agreement has been drawn up, in which the interests of the workmen and employees are safeguarded. This agreement has also provided for a standing committee, upon which the Municipal Council is strongly represented, to see that all the various conditions and restrictions are observed, and the cost to the consumer of the "red tape" with which the electricity supply business is bound up is probably an appreciable percentage of the price he pays for electrical energy. Yet the simple organisation necessary to guard against the results of a strike of stokers has been disregarded, although there was a serious enough warning about eighteen months ago, when the whole electricity supply in Paris was suspended for 29 hours through a similar cause. If the boiler hands in any one of the electricity works in London struck work, there would be enough volunteers to take their place before the steam pressure had dropped sufficiently to necessitate a cessation of supply. In Paris, in spite of—or perhaps because of—the municipal control, things are very different, and the decision of a few men to cease work upon an arbitrary order of a Trades Union secretary is sufficient to do irretrievable damage to the electricity supply industry. It is stated that the whole trouble was due to 100 stokers striking work, and yet it appears that these 100 stokers, in spite of their wilful neglect of discipline, and their obvious violation of the terms upon which they are engaged, are still in the service of the electric lighting companies. Had a similar strike occurred in the various London electricity works, the probable course would have been that telephone messages would have been sent to the various police stations and men off duty would have been sent as volunteer stokers, while men on duty would have been told off to protect them. While these were coming, there would have been a sufficient number of hands in the station to keep the pressure up. Moreover, we cannot but think that here an arbitrary strike of this sort would have been punishable as a criminal offence in view of the serious public danger consequent upon a total extinction of the lights. In addition to the public inconvenience caused by the Paris strike, there is no doubt that this second attack will have done great damage to the electrical industry in France generally. The public has begun to lose confidence in an illuminant which to all appearances is dependent on keeping a number of workmen and employés in good humour, and the continuity of which can be broken by the irresponsible action of a hundred dissatisfied stokers. Already there is a tendency in Paris to revert to gas lighting, and motor-users are getting nervous also. As is well known, a loss of consumers has its effect not only on the supply companies but on every branch of the electrical industry, for it means a diminution in the output of machinery, lamps, and all the numerous accessories, and a drop in the volume of contracting work. In their own interests, the electrical community in Paris should not take this blow "lying down," and no step should be spared to bring the offenders to justice. Even a socialistic people can surely realise that a general loss of this nature reacts on the workmen themselves, and that the action of this band of stokers may eventually result in throwing thousands of other hands out of work. Punishment not only of the strike leaders, but also of the strikers, should be brought about if there is any means of effecting this.

Telegraph Traffic.—There are a few more announcements to make this week in regard to interruptions and repairs of telegraphic communication. The opening of the new cable between Sevastopol and Varna in Bulgaria took place on the 2nd inst. The cable between Kotonon and Grand Bassam, interrupted on July 20th last, was again restored to working order on the 4th inst. On the following day a break occurred in the cable connecting Kwandang and Menado, in consequence of which telegrams will be transmitted *viâ* Yab to the latter place and those for other places *viâ* Penang-Singapore or Saigon. The Indo-European Telegraph Co. have suffered an interruption to their land-line between Djoulfa and Tabriz, which took place on the 6th inst., but was repaired on the following day, and again interrupted on the 8th inst. The cable betwen Cadiz and Tangier, which has been inoperative since June 3rd last, was put into working order once more on the 8th inst. The cable between Trinidad and Demerara, British Guiana, once more succumbed on the 31st ult., but was repaired on the 9th inst. by the company's own repairing steamer.

STRIKE AT THE PARIS ELECTRICITY WORKS

LAST Thursday the stokers at practically all the Paris electricity supply works repeated on a smaller scale their strike of last year. On this occasion it appears that, instead of a regular strike, a cessation of work for two hours was ordered, and the actual interruption of supply lasted 70 minutes. This was, however, sufficiently serious, as the time chosen for stopping work was 8 p.m., when the theatres and music-halls are giving their performances, and the business at the cafés is at its briskest, and also when the traffic in the central streets is considerable.

The workmen's syndicate and the companies are still at issue over a number of minor details relating chiefly to contributions to superannuation and widows' funds, &c., and the syndicate has, moreover, not been definitely recognised by two of the companies. No definite grievance or hardship has been alleged by the workmen themselves, however, and some of the Paris correspondents regard the incident as a "joke" on the part of the secretary of the electric light workers' trade union, a man named Pataud. According to some accounts, the Confédération Generale de Travail, the general Labour Council, had expressed a doubt whether Pataud's organisation of his union was effective, and he thereupon issued strike notices in order to demonstrate this. These notices were issued to all the men employed by the electricity companies, and some 100 stokers obeyed the mandate, striking work but remaining at their posts presumably to intimidate others from taking their places.

It appears that some sort of action has now been taken by the managers of the electricity works to prevent a recurrence of this incident, for the reports of an interview between them and M. Clemenceau (the Premier and Minister of the Interior), state that they expressed their confidence that their organisation was now sufficient for this without outside assistance. Nevertheless, M. Clemenceau has given orders for a detachment of Army Engineers, sufficient to take the places of the men in the electricity works, to be posted in Paris.

A Paris correspondent informs us that the Edison Company has been successful in an action brought against them by the administration of the Comédie Française for damages owing to the fact that the theatre was unable to give performances on March 8th and 9th last year, the date of the former strike. The defence was *force majeure* and that the company was guilty of no negligence as the strike was impossible to foresee.

Electric Traction in Lancashire.—The *Pall Mall Gazette* states that the Midland and London & North-Western Railway Companies propose converting some portions of their lines in Lancashire and the Midlands to electric traction. The Lancashire & Yorkshire Company, it is stated, also intend constructing additional electric railways in Lancashire.

Fatal Accident on Metropolitan Railway. An inquest was held on Tuesday at the Kensington Coroner's Court upon the five-year-old son of a labourer living in North Kensington, who was found lying dead upon the positive rail of the Metropolitan Railway on Saturday. It appears that the child was staying at a relative's house at Acklam-road, Kensington, which backs on to the line, and was thought to be in the garden, but had apparently climbed the low wall of the garden and got on to the railway. The driver of a train from Westbourne Park to Notting Hill stated that on Saturday morning when approaching Portobello-road Bridge, he saw smoke coming from the opposite line and noticed a child on the rails with its wrist on the positive rail and its body on the running rail. He stopped his train, and, taking a rubber mat, removed the body with it. The positive rail at this spot is protected by the usual wooden board. The landlord of the house said that the wall at the bottom of the garden was only 3 ft. high, and the coroner expressed the opinion that he ought to have warned his tenants of the danger of such a low wall in close proximity to the electric railway. The landlord gave an undertaking to rebuild the wall, and the jury, in returning a verdict of accidental death, stated that high railings should be placed at the backs of all the gardens at the spot in question. No amount of protection of conductor rails will prevent accidents like this, and it is quite probable that the child would have been run over and killed by a train even if the line had been working by steam.

A SINGLE-PHASE GOODS LOCOMOTIVE

A DESCRIPTION is given in the *Electric Railway Journal* of a single-phase locomotive which has recently been completed for the Windsor, Essex, and Lake Shore Railway of Canada for use for such purposes as ballast and goods trains, and also for dealing with extra excursion passenger traffic. The locomotive is 35 tons in weight and of the following general dimensions:—Length, 37 ft.; width, 8 ft.; distance between centres of trucks, 20 ft. 3 in. In designing this locomotive special attention was paid to having motors, wheels, gears, and axles interchangeable with those on the motor-cars. The latter are equipped with two Westinghouse 100-h.p. motors in parallel, while in the locomotive there are four motors of the same type, the two motors on each truck being in series and the two sets in parallel. The weight of each motor is about 4,900 lb. The body is arranged with sliding doors, and has plenty of space which can be used for luggage. A driver's cab is provided at each end. The frame is mounted on two trucks with 36-in. wheels. The distance between centres of wheels is 6 ft. 6 in. The axles are 6 in. in diameter, and are the same as used on the interurban cars of the company. There is one motor on each axle. The weight of the truck with wheels and without motors is 9,750 lb. The locomotive is provided with the unit switch system of control of the ordinary Westinghouse type. A 104-volt tapping is taken from the main transformer for the circuit supplying the lights, the compressor motor and the motor generator for charging the batteries used on the control circuit. As the controller was originally arranged, the first step allowed of the closing of a sequence of the first four of the unit switches. This was, however, found to give more rapid acceleration than was convenient for shunting and such purpose, so an auxiliary control switch was added in each of the cabs in series, with one of the interlocking wires, so that the sequence of switches could be interrupted as soon as the second unit switch closed. The first voltage step was thus made 296 volts instead of 413 volts, the remaining four controller positions actuate the remainder of the unit switches, and apply progressive voltage steps up to 620 volts to the motors. All of the electrical apparatus, except the car motors, are placed inside the locomotive. The storage battery, motor generator, reverses, preventive coils, and the switch group are secured to a structure made of 4 in. × 4 in. angle iron placed in one corner of the locomotive. It was intended to use 1,100 volts in Windsor and 6,600 volts over the rest of the line, and the car equipment was so planned that a change to the lower voltage may be made without altering the equipment. The auto-transformer, which is oil-cooled and of 200-kw. capacity, is placed in a diagonally opposite corner from the switch group. The line switch is placed immediately above the auto-transformer, and is just below the pantograph collector. All the control wiring is in iron armoured conduit. All the control apparatus of the car, which includes the switch group, reverser, line switch, and pantograph, is electro-pneumatically operated. The air compressor, which is driven by a single-phase motor, is placed between the switch group and one of the sliding doors on the side.

So far the locomotive has only been used to pull gravel trains, and up to the present not more than six loaded flat cars have been hauled at one time. From the ease with which these cars are handled, it is probable that twelve flat cars loaded with gravel will make a fair load for the machine. The motors are geared to run the locomotive at a maximum speed of about 35 m.p.h., but it is found to run about 40 m.p.h. on level tangents.

Lowering Gear for Arc Lamps.—We have received from the London Electric Firm of Croydon particulars of some alterations to street arc lamp-posts which they have carried out to the order of Mr. Brydges, electrical engineer to the Corporation of Eastbourne. It appears that until recently all the arc lamps in the town were arranged with some form of lowering gear, except four standards of the "lyre" pattern. These have now been altered by the addition of an ingenious lowering arrangement. The contact and suspension device is fixed in the hood of the carrier. A cross-arm is fitted right through the hood, and a wire rope, working over pulleys, unlocks the suspension device, draws the lamp out horizontally clear of the pole, and then lowers it vertically. A single sustaining winch, fitted in the base of the pole (operated in the same direction all the while) performs the whole of these operations, and conversely re-hoisting and taking the weight of the lamp off the rope. The contact-suspension device is positive in action and does not depend on the operation of springs, levers, balls, clutches, or other similar contrivances, and, being on the concentric principle, does not require to be manœuvred to ensure correct polarity.

REVIEWS OF BOOKS

Radio-Telegraphy. By C. C. F. Monckton. 263 pp. 5½ in. by 8¼ in. 173 illustrations. (London: Archibald Constable & Co.) 6s.

This book suggests a pupa breaking through its mathematical covering and showing itself as a fully developed insect. It also brings home to us that a new kind of electrical engineer has been quietly growing up in our midst without our recognising the fact.

The traction man knows plenty of telegraph men and enough of their work to take an intelligent interest in it; the telephone man has friends among the station engineers, and knows what the electrochemist is about—more or less. But how many of us know the wireless man? He has kept to his own class, for patent reasons probably, but he is here none the less; for wireless is no longer a mere mathematical theory, but has risen to the ranks of engineering.

In saying this there is no wish to minimise the work of the mathematical men of science. Wireless is due to them, and to them alone. The fact that it has commercial value, and that the public perhaps put that value too high, has given the means of carrying out the work, but the credit is theirs. None but the mathematician could deal with it at the start, and well has he risen to the occasion, but the ordinary engineer is taking his share now. The latter, as we said, is still a man apart, brought up to look at things from a different side to the ordinary man. The wireless man lives in a static world. A current, to him, is "something that happens when you charge a body"; that the same phenomenon occurs when you close a battery or dynamo circuit is interesting perhaps, but of minor importance. He will doubtless lose this feeling somewhat when he mixes with other engineers, but, on the other hand, let us hope that they will learn from him to regard displacement currents and the like as real live things; just as real commonplace facts as volts and amperes. They will then benefit as much as he, if not more. Mr. Monckton has the advantage of having been an electrical engineer, and an experienced one, before he specialised in wireless telegraphy. He is able, therefore, to take a broader view than the ordinary "wireless man," and his book ranks as a first-class engineering treatise. It deals with the whole matter without any mathematics at all, which is rather a *tour de force*. Some of his preliminary matter in the first 60 pp. he would perhaps have left out had he realised how much ordinary men know; some of it he might have expanded, had he realised how little. It is rather a pity that the author was brought up on tubes of force, and has not given them up yet. Though useful in their place, they are so bad for explanation, and convey such a very inadequate idea of facts to the average man. A few hydraulic or pneumatic analogies would have given a much clearer conception, and one feels that the author was quite able and willing to supply them had he known they would have appealed better to his readers, for he makes full and excellent use of the vibrating string when explaining waves and resonance.

We would advise the engineer who starts with a prejudice against wireless to begin at Chapter X., on measurements. When he finds that he is going to deal with average currents of two or three amperes going to line—just common amperes measured on an ammeter—and having a maximum value of some hundreds, he will realise that he is getting towards something he can appreciate. Mere volts, however big, he has but little respect for; but big volts "with the amperes behind them" are worth talking about. It will also appeal to him when he finds the whole problem of wireless expressed in his own language; given so many horse-power put in at one end, how to transmit it to the other with least loss: though he will, we fear, consider the efficiency of transmission somewhat low.

The different forms of aërial, earthed or insulated, close- or loose-coupled; the various receivers and other instruments, and little working difficulties, such as dawn and sunset troubles, are all now things in every-day work, and are described and explained by Mr. Monckton with no more reverence than a traction man uses to trolley pole.

The book closes with chapters on Lodge, Telefunken, and Poulsen experimental stations, field telegraphs and radio-telephony.

Printing and illustrations are alike excellent.

Electrometallurgy. By John B. C. Kershaw. 303 pp. 5½ in. by 8¼ in. 61 illustrations. (London: Archibald Constable and Co.) 6s.

The greatly increased interest which is being taken in electrochemistry and electrometallurgy is evidenced by the large amount of literature upon the subject which is being published. The book before us upon electrometallurgy commences with an historical survey, and in this section various definitions as to what electrometallurgy is, and as to how the electric current acts in refining are given. It would have been as well to leave out the definitions, as they convey nothing to one who does not know, and are so very inadequate to those who do know. We might point out that Davy did not commence to experiment with the electric current in 1806; he began at least five years earlier, but took up the subject again in 1806. It is extraordinary that so far back as 1851 Charles Watt took out a patent for electrochemical and electrometallurgical processes, in which he described how many processes might be carried out which only recently have been perfected, if we can ever call a process perfect, such, for example, as the production of the alkali metals, chlorine, hypochlorites, chlorates, and the refining of metals. In Watt's days it was out of the question to work any of these processes, because there was no possibility of obtaining suitable electrical energy. Although to-day the bulk of the copper, for geographical and geological reasons, is refined electrochemically in America, it must not be forgotten that it was Elkington in 1869 in this country who first erected a copper refining plant. In fact, so carefully was the process worked out that even to-day, when thousands of tons are being weekly refined by electrical methods, the process only differs in minor details to the initial one.

The descriptive part of the book commences with the production of aluminium. The rise of this industry is indeed remarkable. In 1886 the first attempts to obtain the metal by electrometallurgical methods were commenced by the brothers Cowles, and the process was worked both in this country and in America upon a considerable scale. It consisted in the reduction of alumina in a resistance furnace by means of carbon, but although it worked very well for the production of aluminium alloys, it could not be used for the manufacture of pure aluminium. It is extraordinary that just as the chemical processes for the manufacture of aluminium by reduction of aluminium chloride with sodium had reached its zenith, and the price of the metal had dropped to about 2s. 6d. per pound, it was forced out by the advent of a satisfactory electrochemical process. The methods of Héroult in France and Hall in America, which are essentially the same, were first introduced in 1888, and by 1890 compelled the hitherto successful works which employed the chemical process to shut down. Since then the production of aluminium has shown a steady increase, although the price has fluctuated considerably. We

Digitized by Google

are not likely, however, to see any very great rise in the price of this commodity in the near future, owing to the number of new undertakings which have been or are about to be started. In connection with aluminium, the use of this substance in "thermit" is referred to, and an interesting photograph of the repair to the stern of a steamer is shown.

Beside purely electrometallurgical processes, the manufacture of glass and quartz by means of the electric furnace are also described. Quartz vessels are manufactured by the Thermal Syndicate at Wallsend-on-Tyne, so the author tells us. Is the author not aware that in London the Silica Syndicate, Ltd., produce transparent silica ware as distinct from the rather rough and non-transparent product of the Thermal Syndicate? It should, however, be pointed out that both forms have their particular uses.

The book will, we think, be found useful to those who wish for a general idea as to the position of the electrometallurgical industries. It is not written for those who are well up in the subject, because the author in his preface says that his "aim has been to give a brief and clear account . . . in language that can be understood by those whose acquaintance with chemical or electrical science may be but slight." A remark like this rather disarms criticism, but we are inclined to doubt the wisdom of writing books of this class for such a *clientèle*.

Elementary Manual on Applied Mechanics. By Andrew Jamieson. Eighth Edition. 455 pp. 4¾ in. by 7½ in. (London: Charles Griffin & Co.) 3s. 6d.

A REVISED and enlarged edition of this well-known text-book on applied mechanics. The additions include some notes on the terms and definitions of words used in measuring pressures; and a series of definitions emphasising the distinctions between solids, liquids, and gases, and between perfect, viscous, and elastic fluids. The chapter on measuring tools and gauges has been thoroughly revised, and now includes a detailed explanation of the uses of Limit Gauges and of Berridge's Tangentometer. The C.G.S. system units of measurement and their definitions, and the definitions of the practical electrical units have been added to an Appendix. The Examination Papers incorporated in the book now include the 1907 papers for Stage I. of the Board of Education; the City and Guilds of London, Ordinary Grade, Part I., 1907 papers on Mechanical Engineering; and the Entrance or Students' Examinations of the Institution of Civil Engineers in Elementary Mechanics for 1907 and February, 1908. The numerical answers to most of the questions are given. The contents of the body of the book are too well known to need comment, but attention may be drawn to the excellent chapter on the screw-cutting and other lathes, which contain a fully illustrated description of an electrically driven hexagon turret lathe.

The Engineering Index Annual for 1907. Compiled from the Engineering Index published monthly in the *Engineering Magazine* during 1907. Pp. 435. 6 in. by 9 in. (London: The *Engineering Magazine*.) 10s.

THE sixth volume of the Engineering Index, which is the second of the annual series, contains the usual useful collection of references to the engineering and technical literature of the year. As in the last volume, the classified system of arranging the items is followed in place of the strict alphabetical order of the earlier volumes. The arrangement is thus generally similar to that of the monthly instalments of the index which appear in the *Engineering Magazine*. The preparation of the index must have entailed a vast amount of labour, but a glance at the list of periodicals dealt with shows that the result can hardly be regarded as complete. The usefulness of such a volume would also be enhanced if it were published in January each year.

Switchboard Measuring Instruments for Continuous and Polyphase Systems. By John C. Connan. 146 pp. 5½ in. by 8¾ in. 117 illustrations. (London: E. and F. N. Spon.) 5s.

IT is not very easy to see for whom this book is written. Not for men who have to use instruments, certainly, though it may be of interest to a certain class of students. It reads throughout as if based not on what the author knows, but on what he has been told, either in lectures, or when set to do cut and dried experiments, or from reading of other men's work. If that is the case, we can congratulate him on the copiousness of his notes and the care with which he has arranged them, and we only hope that he will keep equally copious notes of real work when he comes to it, though he will not find it nearly such an easy matter. If he does he will be able to write an excellent book, for the present one shows most painstaking care in dealing with the matter at his disposal.

The Deinhardt-Schloman Series of Technical Dictionaries in Six Languages. Vol. III. Steam Boilers, Steam Engines, Steam Turbines. Edited by W. Wagner. 1,322 pages. 7 ins. by 4 ins.; about 3,500 illustrations. (London: Archibald Constable & Co.) 16s. net.

THE general arrangement of the third volume of the Deinhardt-Schloman Series of technical dictionaries in six languages is similar to the previous volumes on machine parts and tools and on electrical engineering respectively; that is to say, the ideas are arranged according to subject matter with the German, English, and French expressions on one side of the page, and the Russian, Italian, and Spanish on the other, while suitable illustrations are given in the central space. The latter part of the book consists of alphabetical indices with the Russian words separately, owing to the difference in alphabet. The present volume is divided into sections dealing respectively with boilers, steam engines, and steam turbines, each of which is extensively sub-divided. The illustrations are often very helpful from an explanatory point of view, and contain quite an interesting collection of miniature drawings of a great variety of Continental and British designs of boilers, furnaces, and automatic stokers. The turbine section appears very complete, and here, more especially with regard to the many methods of blade fixing dealt with, the illustrations are sometimes more explicit than the text. As in the last volume, we have noticed some misprints in the list of contributors and revisers which do not speak well for the accuracy of the proof reading.

The Calculus for Engineers and Physicists: Integration and Differentiation, with Applications to Technical Problems; and Classified Reference Tables of Integrals and Methods of Integration. By Prof. Robert H. Smith. Second Edition. 205 pp., 5 ins. by 7½ ins.; 32 illustrations. (London: Charles Griffin & Co., Ltd.) 7s. 6d.

IF an engineer who knows a little practical calculus already will go through this book and pick out the plums, he will find it a very pleasant one. So, also, will the man who read calculus at school and college, but learnt it as a mass of useless work and meaningless mental gymnastics, for it will show him that calculus is neither one nor the other; but the man who has no previous knowledge will, we fear, hardly appreciate it. One feels throughout that the writer has acquired his grasp of the subject by the methods of the schoolmen, and himself feels and thinks in their language, not in that of the engineer. To use an analogy, the book resembles a treatise written in English by a Frenchman; we admire his cleverness in doing it at all, and, with our insular superiority, we acknowledge his sense in thinking English the better language, although the result is not really English, and many of the expressions are only to be understood by those who know French. Most of the practical examples are well chosen, and the classified list of integrals will be very useful.

First Stage Steam. Written to meet the requirements of the Board of Education Examination, and containing the examination papers set in the years 1901-1907. By J. W. Hayward. Second Edition. 247 pp. 4¾ ins. by 7 ins. 132 illustrations. (London: W. B. Clive; The University Tutorial Press.)

THE object of this manual is to furnish information of the requisite quantity and quality to candidates for certain examinations of the Board of Education, and the limitations imposed by these conditions must be borne in mind when considering the suitability of the book for instilling into the minds of engineering students the principles upon which their future work will be based. The author has, however, on the whole, succeeded in rising above the level of the mere "cram" book, and a good feature of the scheme is the provision of a large number of explanatory figures, which strike the happy medium between diagrammatic representations of the principles involved and unnecessarily elaborate scale drawings. There are, of course, many parts of the subject which cannot be taught by a book without familiarity with steam plant at work, but the practical information given will be a help in enabling the student to understand what he sees. The explanations are clear and succinct, and the examination candidate is provided with plenty

Digitized by Google

of questions and problems to practise on. The whole treatment is, of course, necessarily superficial, and only the merest introduction is given to the science of thermodynamics, as the employment of anything more than the simplest mathematics is forbidden.

Telephones: Their Construction, Installation, Wiring, Operation, and Maintenance. By W. H. Radcliffe and H. C. Cushing. 165 pp. 4 in. by 6¾ in. 125 illustrations. (London: Crosby Lockwood & Co.) 4s. 6d.

This book is dedicated to the amateur and small contractor. It is of American origin, but this in itself is of no great importance, as the practice in this country is in many respects similar. In the English edition, however, the introductory chapter relating entirely to American conditions should have been omitted, as might also the descriptions of the Edison transmitter, and the Fuller gravity, and Edison cells. The space so saved might well be occupied by descriptions of the popular hand micro-telephone and of the constructional details of the various switch-hooks. The latter device is called a hook switch, gauge is written gage, and another curiosity—which, however, is, we think, a printer's vagary rather than an Americanism—is "tantetion" for attention. Many of the illustrations are well-executed, and much of the advice is sound; yet we cannot but think that, unless the reader particularly desires to gain an acquaintance with American practice, he will be equally well served with one of the English books on the subject.

Electric Bells, and All About Them. By S. R. Bottone. Seventh Edition. 154 pp. 4¾ in. by 7½ in. 81 illustrations. (London: Whittaker & Co.) 2s.

Commencing dutifully with Thales, "who flourished about 600 years B.C.," experiments with sealing-wax and pith-balls, lists of conductors and non-conductors, and pictures of magnets with fluffy poles, the author leads his readers through the zinc-copper-sulphuric acid cell, the Smee, Daniell, and gravity cell to the Leclanché. Several forms of the latter are described, and the amateur is told how to make a dry cell. Previously to explaining Ohm's law, Mr. Bottone incidentally refers to current as "the amplitude of the continuous vibrations kept up in the circuit." He then gives illustrations of cells connected in series and in parallel—the latter in rather a clumsy manner. All this occupies but 57 pages; the remainder of the book gives amateurs instructions how to make electric bells, pushes, burglar-alarms, fire-alarms, and indicators. Magneto bells are dealt with briefly, and, in the last few pages, bell circuits connected to the supply mains are mentioned. We are glad to see that the amateur is warned that he will probably have trouble if he attempts to use the latter method. Although Mr. Bottone adopts as his sub-title "A Practical Book for Practical Men," the book is evidently written for the amateur.

English Prices with Russian Equivalents. By A. Adiassewich. 185 pp. 4 in. by 3¼ in. (London: E. & F. N. Spon, Ltd.) 1s. net.

This little pocket-book, which should be found useful to firms doing export trade with Russia, is on the same lines as a previous compilation dealing with French prices, issued by the same publishers. It consists of tables calculated at fourteen rates of exchange in Roubles per Pood, giving equivalent prices in English currency per lb. and per ton. We may mention that one ton is equal to 62·0275 poods, and that the equivalent of £10 is about 94 roubles 50 kopecks, more or less according to the rate of exchange.

Aldum's Pocket Folding Mathematical Tables. For the use of Engineers, Architects, Students, &c. 3¾ ins. by 6¼ ins. (London: E. & F. N. Spon.) 4d.

This six-page folder contains logarithms and antilogarithms to four figures, and a table of natural sines, tangents, and cosines, &c. Some useful constants taken from the Examination Tables of the Board of Education are also given. The folder is made of faced linen, and is convenient for the pocket; but the type is bad, the figures in some cases being difficult to read.

Questions and Answers in Electrical Engineering. By A. E. Moore and F. Shaw. 151 pages. 4¾ ins. by 7½ ins. 54 illustrations. (London: Longmans Green & Co.) 2s. 6d.

In the words of the preface, "this little book has been compiled primarily for the assistance of those students who intend to become candidates for the Elementary Examination in Electrical Engineering, held by the City and Guilds of London Institute," but we can thoroughly recommend this book to any students in electrical engineering. Although it consists entirely of solutions to about 150 questions set by the City and Guilds of London Institute in the preliminary grade of Electric Lighting, from 1899 to 1907 inclusive, the majority of the questions are of an eminently practical nature, and the solutions contain much valuable information with regard to wiring, testing, and the simpler problems connected with lighting installations. The descriptions of instruments and other electrical apparatus are very concise, and are well illustrated with carefully executed line drawings.

The Electron. The official monthly organ of Siemens Stafford Institute. Vol. I., Nos. 1 and 2. (Stafford.) 6d. each issue.

We have before us the first two numbers of a monthly magazine conducted by the employees of Messrs. Siemens Bros. Dynamo Works, Ltd., which forms the journal of the Siemens Stafford Institute, and also contains literature of general literary and scientific interest. The June issue has for its frontispiece an excellent portrait of Mr. Lee Murray, the present works manager at Stafford, who is well known to many through his connection with the Siemens interests both in Australia and South Africa. A considerable proportion of the pages are devoted to records of the athletic and literary life of the members of the Institute and in associated social, educational, literary and debating sections, and sports clubs, and a most flourishing condition of affairs is apparent in all these directions. Mr. Murray's presidential address to the Engineering Society, dealing with coal and its application to the production of power gas, is published at some length. The second issue contains a good deal of interesting matter to those who are or have been in any way connected with the various Siemens companies, as well as to engineers in general, and fully maintains the level of literary merit of its predecessor. The first article is a long Paper on the Siemens-Schuckert single-phase series motor, by Mr. M. Schenkel. The next is a historical article outlining the development of the English Siemens firms and the various changes which they have passed through from time to time, from the establishment of the small factory in Millbank Row in 1858 to the present division of the undertaking into the two closely allied but separate companies, whose manufacturing work is carried on respectively in the historic establishment at Woolwich and the extensive modern works at Stafford. This is followed by the first of a series of biographies of prominent men in the history of the Siemens firms, commencing with a reference to some of the earlier members of the Siemens family. The arrangement and get-up of the publication are excellent, and its contents reflect a most praiseworthy spirit of *esprit-de-corps* among the employees.

THE FUNCTIONS OF FLYWHEELS

By H. M. Sayers

THERE are three main purposes for which flywheels are used in electrical generators and the prime movers or engines driving them:—1st: To reduce the cyclic variation of speed due to the variation of torque or turning moment of the engine. 2nd: To reduce the speed variation due to sudden variations in the external load. 3rd: To restrain "hunting" in alternators by giving the rotating parts (including the flywheel) such a "free oscillation period" that resonance with forced oscillations, due either to the prime mover or to the load, is improbable. "Alternators" for this purpose may be read to include synchronous motors and rotary converters.

The relative importance of these flywheel effects varies with the characteristics of the engine and generator, the type of the latter, and the nature of the load.

Steam engines built for driving generators have usually two or three cranks, and give a fairly even turning moment, so that they make little demand upon the flywheel for the neutralisation of varying torque. If the load includes a lighting supply, and the engine has a low rotative speed, sufficient flywheel capacity is necessary to prevent flickering of incandescent lamps. The point needs attention in such engines working at early cut-offs and high pressures and vacuua; but, as a general rule, the flywheel required for the other purposes will be ample for this one.

With gas and oil engines the case is very different.

Digitized by Google

In the extreme case of a single-cylinder engine working on the Otto cycle, there is but one impulse every two revolutions, and generally, whatever the number of cylinders, the impulses per revolution number only one-quarter of those which would be delivered by an equal number of double-acting steam cylinders. In addition to the relative infrequency of positive impulses, the "negative work" of the compression stroke adds to the cyclic irregularity, and to the energy storage capacity required of the flywheel. The requirement is generally defined by the specification that the variation in the speed of rotation over a cycle shall not exceed a certain percentage of the mean speed. To obtain the desired result the flywheel must be of such proportions that in passing from the maximum to the minimum speed it shall lose sufficient kinetic energy to supply the load, including friction and compression losses, between the end of one impulse and the commencement of the next; or, more exactly, during the time that the crank effort is less than that corresponding to the load. In the case of a single-cylinder gas or oil engine it may be taken that the flywheel has to supply the load for three strokes out of four by its deceleration, being accelerated during the fourth or impulse stroke from the lowest to the highest speed allowed by the specification, and decelerated during the three following strokes.

Then if the mean speed is N revolutions per minute, the specified permisible variation P revolutions, so that $N+\frac{1}{2}P=N_1$ and $N-\frac{1}{2}P=N_2$ are the maximum and minimum speeds during the cycle; and if the energy to be alternately stored and given up is F foot pounds, then $\frac{F}{N_1^2-N_2^2}=M$, where M is the foot pounds of kinetic energy stored in the flywheel at the speed of one revolution per minute, and is proportional to the moment of inertia of the flywheel about its axis. Professor Perry is responsible for introducing this quantity into mechanical calculations (see Chapter XI. of Perry's "Applied Mechanics"), and shows that $M=\frac{I\pi^2}{1800}$, where I is the said moment of inertia, when M is in foot pounds, the dimensions in feet, and specific mass in pounds per cubic feet.

An example from actual practice will best illustrate this. A single-cylinder Diesel oil engine rated at 80 b.h.p. at 160 revolutions per minute is specified to have a maximum variation of $\frac{1}{70}$, *i.e.*, of $\frac{160}{70}=2{\cdot}3$ r.p.m., so that the limits of speed are 161·15 and 158·85. There are 80 impulse strokes per minute.

The indicator card, Fig. 1, taken from this engine at full load and speed shows what the flywheel has to do.

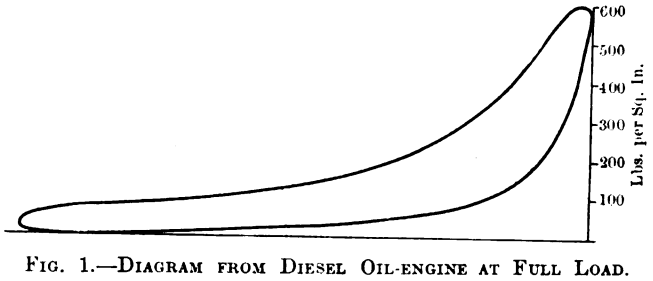

Fig. 1.—Diagram from Diesel Oil-engine at Full Load.

The area enclosed between the atmospheric line and the upper curve represents the gross work of the impure stroke, and that between the atmospheric line and the lower curve represents the negative work of the compression stroke; the difference is the "indicated power" per cycle. The scavenger and suction strokes cannot be distinguished from the atmospheric line.

The M.E.P. is 131·25 pounds, and as the cylinder dimensions give the constant of 384 foot pounds per stroke per pound pressure, the foot pounds available for useful work and engine losses during four strokes or one cycle are 50,400. The flywheel has to provide three-fourths of this, or 37,800 foot pounds.

But the M.E.P., as above stated, is the difference between the mean pressure in the impulse and the compression strokes, so that the impulse stroke diagram is really the whole area between the atmospheric line and the upper curve, and the compression diagram that between the atmospheric line and the lower curve. The two M.E.P.'s on this basis are respectively 199·3 pounds impulse and 68·05 compression. The latter corresponds to 26,130 foot pounds, so that the flywheel has to take up and give out 63,930 foot pounds per cycle. It will be noted that the heat losses in the compression stroke are not here separately accounted for; they are included with the other engine losses, as are the negative work done in the scavenging and suction strokes. The indicated energy of the impulse stroke is thus 76,530 foot pounds, of which the flywheel takes up 63,930, with a speed varying from 158·85 to 161·15. Then

$$\frac{63930}{(161{\cdot}15^2-158{\cdot}85^2)}=\frac{63930}{740}=86{\cdot}4.$$

The flywheel provided had a rim 10·75 ft. outside diameter, 7·75 inside diameter, and 1 ft. broad. Taking cast-iron as weighing 485 pounds per cubic foot, then

$$*\,I=485\times1\times(10{\cdot}75^4-7{\cdot}75^4)\times0{\cdot}00305=14{,}379 \text{ or}$$

$$M=\frac{485\times1\times(10{\cdot}75^4-7{\cdot}75^4)}{59{,}814}=79, \text{ very nearly,}$$

so that the flywheel rim provides about 90 per cent. of the required capacity. The arms, the crank, and the connecting rod may be reckoned towards the balance, and the dynamo armature also assists, with the result that no flicker is perceptible on the lamps. The weight of the rim above described is about 6¼ tons.

It will be obvious that governing by missing explosions calls for extravagant flywheel capacity, and this method ought to be quite out of date for electrical work.

The variation in the speed is not steady. The whole acceleration is imparted to the flywheel during the impulse stroke, while the deceleration is spread unequally over the three following strokes, being considerably greater during the last or compression stroke than during the scavenging and suction strokes. The result is often visible in a quick brightening of the lamps during part of the impulse stroke, and illustrates the fact that the rate of variation is as important as the range when steady lighting is an object. It is also of importance when the running of alternators in parallel is required, and properly belongs to the consideration of the flywheel in that connection.

The use of the flywheel in reducing speed variations due to sudden variations in the external load is confined to cases where the load peaks are of short duration, such as in traction and other power work; and by a natural extension flywheels are now employed in the Ilgner and allied systems for driving winding gear, rolling mills, and other machinery in which the demand for power varies through a wide range, in a cyclic fashion, with fair regularity.

Lighting loads vary in a continuous and comparatively slow manner, and do not permit of much speed variation, hence flywheels are of little use on generators for lighting in respect to load variations.

Traction loads, on the contrary, are continually rising and falling in a jerky way, so that the instantaneous output rarely corresponds with the engine power, the difference being made up by the alternate acceleration and deceleration of the flywheel. It is usual to specify the speed regulation of engines in some such way as the following:—"The variation of speed between no load and full load shall not exceed 5 per cent., and with the full load thrown on or off suddenly the sudden

* I for a hollow cylinder of length l, outside diameter D, inside diameter D_1, and w pounds per cubic foot $=\pi l(D^4-D_1{}^4)\times0{\cdot}00305$, and $M=\frac{\pi l(D^4-D_1{}^4)}{59{,}814}$. Perry, "Applied Mechanics," *loc. cit.*

Digitized by Google

rise or fall of speed shall not exceed 7½ per cent." The first clause has mainly to do with governing, the second with flywheel action. Taking the case of a single-crank double-acting engine running light at full speed. On throwing on the load the power is supplied at the expense of the kinetic energy of the flywheel, including in this term all the rotating masses, and the speed falls until the action of the governor admitting more steam supplies the demand from the cylinder. The important question is then: During what interval of time has the flywheel to supply the full load? This will vary in the same engine with the piston position at the moment the load is put on. If thrown on immediately after steam is cut off, there will be an interval of one stroke, or half a revolution, before any additional steam supply commences to take effect. But if the load is thrown on at the commencement of a stroke, the lag of the governor will in most cases prevent additional steam being given on that stroke, so that the flywheel may have to supply the load for nearly one and a half strokes, or three-quarters of a revolution. Then, to satisfy the specification, the flywheel M must be such that $M \times [N^2 - (0{\cdot}925N)^2] = F$, where F is 0·75 of the full load foot pounds per revolution, reckoned on the brake horse-power. The specification, as above given and frequently met with, is ambiguous in that it does not define the standard or normal speed on which the variations are to be based. The flywheel calculated as above, with N as the upper, no load speed, would drop 7½ per cent. of that speed on the load being thrown on; but on the converse operation the rise would be at the rate of 7½ per 95 revolutions, or 7·9 per cent. So that to be on the safe side the lower speed should be taken as the standard. The full load speed seems to be the correct one to take as normal on general principles.

On throwing off the load the worst case is that a stroke has just been commenced, and admission is continued to the full load cut-off point. The flywheel has then to take up the full load foot pounds for that stroke, while accelerating from the full load speed to the specified sudden increased speed. This is a smaller number of foot pounds than required at the throwing on of the load, and if the flywheel is sufficient for the throw on, it will be ample for the throwing off requirement. What will really happen in the case supposed is that the acceleration will not be completed by the full load charge of steam, and that the next stroke will have the admission diminished by the governor, but not down to the no load cut-off point. This is all on the assumption that the governor is reasonably quick in its action, but not so quick as to overrun the speed variations and cause "hunting."

For sets of similar output and cylinder arrangement the energy storage needed is inversely as the speed. With a given flywheel the energy storage for a given small *percentage* speed variation is approximately as the square of the mean speed, so that the M of the flywheel should be inversely as the cube of the mean speed. Thus a set running at 100 r.p.m. requires eight times the flywheel M that is needed by a set of equal output running at 200 r.p.m.

This need not mean eight times the weight of flywheel. The M of a flywheel is proportional to the fifth power of its lineal dimensions, whilst its weight is proportional to the cube thereof; so that if a flywheel were known to be sufficient for a speed of 200 r.p.m., then one for a speed of 100 r.p.m. should have lineal dimensions $\sqrt[5]{8} = 1{\cdot}515$ times as great, and will weigh $1{\cdot}515^3 = 3{\cdot}48$ as much. It is, therefore, very nearly right to say that halving the speed means magnifying the flywheel one and a half diameters, when it will be three and a half times as heavy. In any practical application of such a rule, care must be taken that safe peripheral speeds and stresses upon arms and fastenings are not exceeded; but the design of flywheels is rather outside the present purpose, and will not be pursued further.

The application of electric power to such work as coal winding and rolling mills has led to a special employment of flywheels in combination with motor generators to provide by their acceleration and deceleration the great cyclic fluctuations in power needed. They thus act as accumulators between the fluctuating load and the generators, and as the speed and percentage variation permissible are much greater than can be tolerated on the prime movers, and the flywheel dimensions are not limited as they are when on an engine shaft, such flywheels are much more efficient and economical for the purpose of reducing speed variations due to load than equivalent flywheels on the generators. There are, of course, other advantages, most of which may be summed up in the better load factor of the generators and the distributing system. The calculations for such flywheels present no difficulty if the power cycle and period of the operation are known. In most of the systems in use the permissible speed variation is made great by the use of variable field excitation, or some form of "boosting" on the generator side of the converter, so that the voltage of the supply to the motor is kept up through a wide range of converter and flywheel speed, and the storage capacity per ton of the flywheel is comparatively large. Given these elements, the problem is then to provide a flywheel that in decelerating from the maximum to the minimum speed will give out the required number of foot pounds, exactly as in the oil engine example above worked out. The required energy will be, roughly, the product of the mean excess of power over the steady power supply called for by the work, into the duration of the excess demand per cycle, with due additions for conversion and other losses, but this will be modified by the electrical arrangements and the extent to which the motor or driving side of the converter is permitted to assist the flywheel by a larger intake from the mains during the deceleration period. Descriptions of several of these flywheel systems, due to Mr. A. P. Wood Ilgner, the Westinghouse Company, and others, will be found in Vol I. of Electrical Engineering.

The special use of flywheels on alternators is a branch of the parallel working of alternators, and lends itself to an abstruse analysis which will not be attempted here. Those interested may be referred to the two Papers read by Professor Bertram Hopkinson in 1903 to the Royal Society and the British Association. The stable parallel running of alternators is primarily due to such an electrical and magnetic design that the slightest difference of phase produces a considerable correcting moment, bringing up the lagging and retarding the leading machine.

The relation between this correcting force per unit of phase displacement and the moment of inertia of the rotating parts determines the free oscillation period of the machine, the relationship being such that the period $= \frac{2\pi}{\sqrt{\frac{c}{I}}}$, where c is the correcting force, and I the moment of inertia about the axis.

The value of c is perhaps most easily obtained from the usual design data in the form:—

$c = \sqrt{\frac{E i_o}{p}}$, when E is the open circuit voltage, i_o the short-circuit current at full speed, and $\frac{p}{2\pi}$ = frequency.

The moment of inertia I is that of the portion of the armature corresponding to one pair of poles (because the unit of angular displacement used is phase angle), and if the above expression is to give the period in seconds, I must be taken in centimetre × gramme × 10^7 units, *i.e.*, in kilogrammes × metres.[2]

Digitized by Google

An alternator, synchronous motor, or rotary converter may be intrinsically unstable, as Professor Hopkinson shows, if in the first place the reactance Lp exceeds the ohmic resistance R; and if, in the second place, there is insufficient "viscous resistance" to phase swinging. The first-named condition of instability is usually present; the "viscous resistance" is mainly that due to eddy current caused by the swing of the armature about its mean position, and can be provided by the use of solid pole-pieces or copper bars threaded through the pole-faces to form a grid. The addition of flywheel power, or increase of I, does not improve the stability, but increases the period of the free oscillation. It follows that machines afflicted with intrinsic instability of this kind require an electrical or magnetic remedy; in some cases an alteration of the exciting current is sufficient, in others some damping device must be added.

Provided that an alternator is intrinsically stable in this respect, it cannot be improved for parallel running by the addition of inertia; in fact, the less the inertia, the more rapid is the action of the correcting force, and the smaller will be the amplitude and period of the swing, so that added flywheel rather deteriorates an alternator well designed in this respect.

If the free oscillation period or a multiple of it should correspond with the period of a cyclic irregularity in the turning moment of the engine or in the load, then hunting or phase swinging will be set up, and it is essential to practical working to prevent such a correspondence between the free oscillation period and forced oscillations of external origin. Here the flywheel comes in, as it increases the I of the armature, and so lengthens its oscillation period. In practical designs the armature period is usually in excess of fifteen times the current period, *e.g.*, at 50 ~ the armature oscillation period will usually be greater than one-third of a second. If, then, prime movers are employed in which there is a cyclic variation having a period between, say, one-quarter of a second and one second, particular care must be taken that sufficient flywheel inertia is added to lengthen the alternator period beyond that of the turning moment, or of the load, in the case of a motor or rotary. The special application of present interest is the driving of alternators by internal combustion engines. There is a danger that the lengthened oscillation period due to excessive flywheel power may set up governor oscillations as between engines, shown by the machines in parallel throwing the load from one to the other. This causes unpleasant voltage fluctuations, and requires alterations to the engine governors. It is not uncommon in alternating stations to run the engines with the governors out of action, or with the governors of only one engine in action, in order to prevent such troubles.

In the case of synchronous motors and rotary converters, it does not appear that flywheels can improve their performance, unless the load or the supply pressure has a cyclic irregularity of a period near to their free oscillation period. Such an irregularity may be derived from the prime mover in the supply station, where the remedy should be applied. If due to the load, an alteration in the exciting current will often prevent the synchronism. It should be said that in calculating the free oscillation period of such machines, the self-induction and resistance of the mains, &c., must be reckoned as part of the armature properties.

Apart from neutralising such synchronous irregularities, a flywheel can fulfil no useful function in the machines considered. It cannot meet fluctuations in the load, because the utmost permissible variation in the machine speed is but a small fraction of the normal speed; if that is exceeded, the machine falls out of step and out of service.

The motor or rotary must follow the generator as closely as possible, and added inertia can but delay the response and increase the work to be done by the "synchronising current" when phase differences occur from whatever cause.

In conclusion, it may be pointed out that the advantages of flywheels have to be paid for both in capital and working expenses. Besides the flywheel itself, heavier shafts and larger bearings have to be provided, and bearing and air friction met by additional power expenditure. In large, high-speed flywheels the air friction is quite a large item, and should be reduced to a minimum by sheeting between the arms, and generally providing a smooth surface of uniform cross-section circumferentially. From railway experiments this frictional loss is of the order of half a horse-power per 10 square feet of surface at a speed of 5,280 feet per minute, which is a little below that generally accepted as the limiting peripheral velocity for cast-iron flywheels; but it is much increased by roughness of the surface, and also if the air is in a confined space, as in a narrow wheel race, while it may go as high as half a horse-power per square foot in extreme cases, such as the rotor of an induction motor with a very small air-gap.

With induction-motor generator sets, especially when working on traction loads, there is no particular objection to the use of flywheels, but in practice there is no need shown for them. The torque of the induction motor increases rapidly when it drops its speed, and increases its slip a trifle under an increased load, so remaining while the load lasts. A flywheel only meets its load while its speed drops. Naturally, the d.c. end of the converter behaves much better under the former than under the latter conditions of driving.

It must not be forgotten that converters of both kinds run at high speeds, and have a considerable flywheel power, without any special addition, and that when it is desired to run them up in a hurry, as sometimes happens, the flywheel is only a hindrance. The general absence of flywheels on such machines is, therefore, thoroughly justified.

TRACK AND THIRD RAIL CREEPING

By E. Goolding

THE gradual movement that often takes place in one direction with both track and third rail is generally spoken of as rail creeping. To those not quite familiar with the term a certain amount of doubt arises, and it is invariably imagined to be synonymous with expansion and contraction. The movement of a rail subject to expansion and contraction respectively elongates and shortens the length of rail, producing, so to speak, a concertina action, but the term creeping is intended to imply a decided and continuous movement in one direction only—that is to say, the rail travels—and although the creeping is partly dependent upon the expansion and contraction of the rail, it must at the same time be considered as quite a separate and distinct condition.

On account of the known peculiarities connected with the creeping of track rails, the subject generally claims a considerable amount of interest. This creeping has been found to be still more noticeable with third rail, but it cannot be said that a corresponding amount of interest has been bestowed on this side of the question, and the object of this article is to put forward results of experiments, and so engender and direct a little more attention to rail creeping.

During the electrification of some 90 miles of steam-operated line, the equipment of the track with third

Digitized by Google

rail introduced some interesting problems of third rail creeping and expansion. Owing to the difficulty of obtaining any data on the subject, and at the same time seeing the obstacles likely to be encountered, a careful investigation of the trouble was instituted.

Although the track and third rails are both supported by the sleepers, and are laid in juxtaposition, the conditions and strains to which they are subject will be found totally different. With the movement, creeping, and working conditions of track rails we are more or less familiar, since we have been afforded ample opportunity of observation, but third rail construction is, comparatively speaking, a modern introduction, and consequently it is not to be expected that we should be in possession of complete information as to its creeping propensities. It is a well-known fact to all railway engineers that to allow for the expansion and contraction which takes place with track-rails, L-shaped shims or strips of iron are put into the rail joints when the rails are being laid. In the case of tramway rails the question of expansion and contraction is of no consideration, inasmuch as the fluctuation in temperature has little or no effect on account of the rails being embedded in the ground. On the other hand, third and fourth rails are exposed, and therefore subject to the variations of temperature, and consequently vary in length (owing to expansion and contraction) in a similar way to the railway track. It does not follow that although the extreme variation in temperature to which the rail may be subjected (between summer and winter) is perhaps 120° Fahr. that the temperature of the rail will vary in the same proportion, for the simple reason that the extremes in temperature seldom last long enough to bring about a greater difference than 80° in the temperature of the rail itself. The section and weight of the rail, of course, makes some difference as to the rapidity with which the rail is influenced by the variation in temperature. It is to be expected that a Vignoles type of rail which possesses a large thin flange and web will on a hot day reach a higher temperature than a bull-headed track rail of the same weight.

The precautions taken to avoid trouble due to expansion of track rails appears from the above to have been very carefully allowed for at each joint, but it is questionable in practice whether each joint opens and shuts in response to the changes in temperature. It is only when great strain is put upon the rails (either in contraction or expansion) that any movement takes place, and then usually only at one joint. The creeping of track rails is partly due to this strain, the actual creeping taking place when the unstable strain existing in the rail is upset by the additional vibration of traffic. The effect of the strains set up by traffic is best understood by considering the following points:—The weight of a train depresses the track rails between the chairs, and, if the chairs have wood bottoms, presses the rails into the chairs, and chairs into sleepers, and sleepers into road-bed. The sum of these depressions may amount to anything from ¼ to 1¼ inch, and the train travelling in this depression produces, as it were, a wave, against which the locomotive is always driving. In addition to the strains set up due to the above causes, there is a further factor to be considered, and that is the pulling action of the locomotive, obtained through the adhesion of the driving wheels to the rail, which has the tendency to stretch the rail in front, and compress it behind. Owing to the many strains to which the rail is subjected, it is in a state of unstableness, and it becomes impossible to find out in which direction the result of these strains will tend to move the rail, the supremacy is only known when the rail creeps.

Generally speaking, there is not much trouble experienced in this country with track creeping, as it is avoided by anchoring the rail at a number of sleepers, and so distributing the strain. This point is mentioned, as it tends to show the marked difference of our permanent-way construction as compared with the American methods, where rail creeping is evidently of far more serious consideration than in this country.

It is said in Mr. Tratman's book on trackwork that on the Eads arch bridge over the Mississippi River at St. Louis, the track has been observed to move by creeping 42 ft. in one month.

The remarks pertaining to the movement of track rails will, to a great extent, assist in elucidating the creeping propensities of third rail. The observations and tests here given were taken at a selected number of points on some 90 miles of third rail, and records were kept during winter and summer. To make accurate observations, stout stakes with a centre pin on top were driven into the ground close to the third rail, and at a fixed distance of 36 inches (from the centre pin in the stake) a punch mark was made on the flange of the rail. A large number of these stakes were planted over the line so as to gather records under all conditions. As soon as the stakes were fixed careful observations were made several times a day, and continued during the best part of 18 months. Two typical records are illustrated in Figs. 1 and 2, but before dealing with them, it would perhaps be as well to mention first, the several points which have to be remembered, connected with the conditions to which the third rail is subject, since the conditions differ very widely from those prevailing with track rails.

The third rail is supported on insulators, and in no way clamped down; therefore (beyond being kept in place by guides on the insulator) it is, so to speak, a free agent, and can be looked upon when in a long unanchored length as an elastic body, having a concertina movement owing to the expansion. The stresses and strains to a certain extent depend upon the variations of temperature, and the ease with which the rail slides on the top of the insulators in response to the fluctuations of temperature. Its movements are more or less defined; but matters do not rest here. It is necessary to go a little further, and consider the complex strains due to traffic. It has been mentioned, when considering the give of the track, that the sleepers sink into the road-bed. This has an important bearing on the movement of third rail, since the insulators are fixed on the end of the sleepers, and consequently as the sleepers are depressed, the insulators are carried away from the third rail. The insulators are not spaced sufficiently far apart to allow the third rail to bend, and follow the movements of individual insulators; therefore the effect of a passing locomotive is to depress the sleepers, and thus take away in rotation the insulators from supporting the third rail. Besides this there is the question of the grade and action of the shoe on the rail, all of which conditions, acting in conjunction with the strain due to expansion and contraction, set up a state of tension, and the supremacy is only notified by a slow or quick creeping of the rail in one direction or another. Should there be no tendency for the rail to move, it cannot be assumed that the rail is not subject to any strain, but simply that the forces exist and are in a state of balance. Thus the conditions mainly responsible for third rail creeping are expansion and contraction, direction of traffic, road bed, and the action of the shoes.

The exact value to be allotted to these respective items is a matter of conjecture, but the above appears to be the order of their importance.

Fig. 1 gives the record taken on 1 in 100 grade, and the movement of the rail is against the traffic, and uphill the maximum movement of 6½ in. was reached on the sixth week, after which the rail slightly receded, and then remained stationary. In some 90 miles of track the writer only observed two instances of the above nature, and since the movement of the rail is the reverse to what was expected, the cause must be looked for as being quite outside the common, and in explanation the movement was attributed to what

Digitized by Google

might be termed a siphoning action of the rail, inasmuch as at the point in question the rail is on a short up grade of 1-120, and continuing on a long down grade, the rail as before mentioned, being able to slide on the insulators, is drawn up the short up grade by the greater pull on the long down grade.

Fig. 2 gives a typical case of creeping, in which case the rail had moved about 3 in. before the test was started, and during a test of two months moved 7 in.,

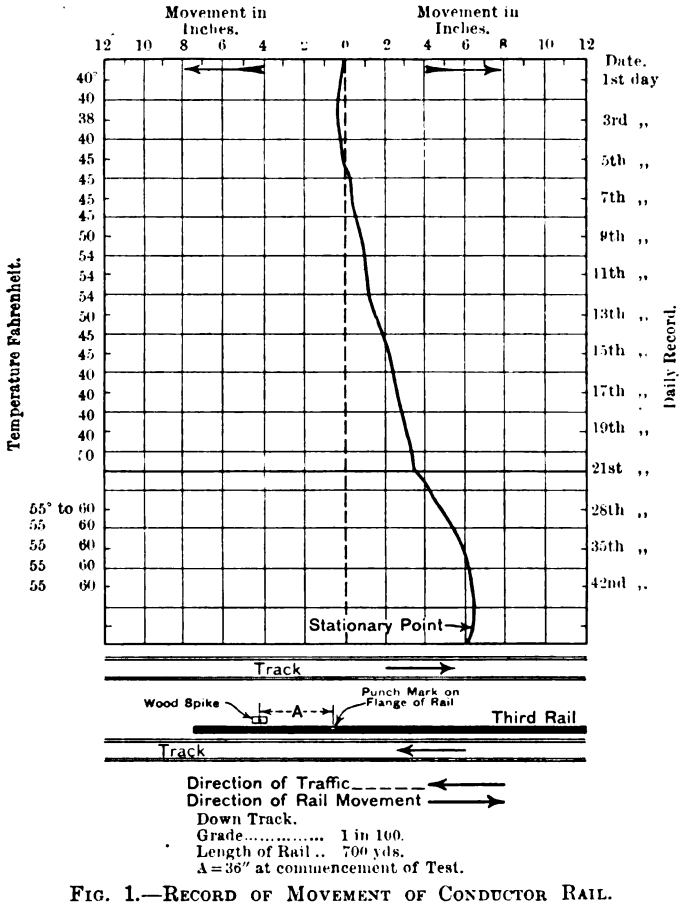

Fig. 1.—Record of Movement of Conductor Rail.

at which point it remained practically stationary. At a large number of points where stakes were driven and creeping was anticipated, there was no movement worth recording. On the other hand, several instances arose of excessive creeping at junctions, and in many cases, owing to the movement of the rail extension, lengths of copper had to be attached to the cable terminal,

From the tabulation of records it is natural to assume that some tangible conclusion could be arrived at to account for the creeping, but it was found that the results were of such a conflicting nature that it was impossible to give any definite statement of rules by which the movement of rails could be gauged. But it was satisfactorily found with few exceptions that the third rail, like the track rail, moved in the direction of the traffic, and that the vibration of the traffic re-

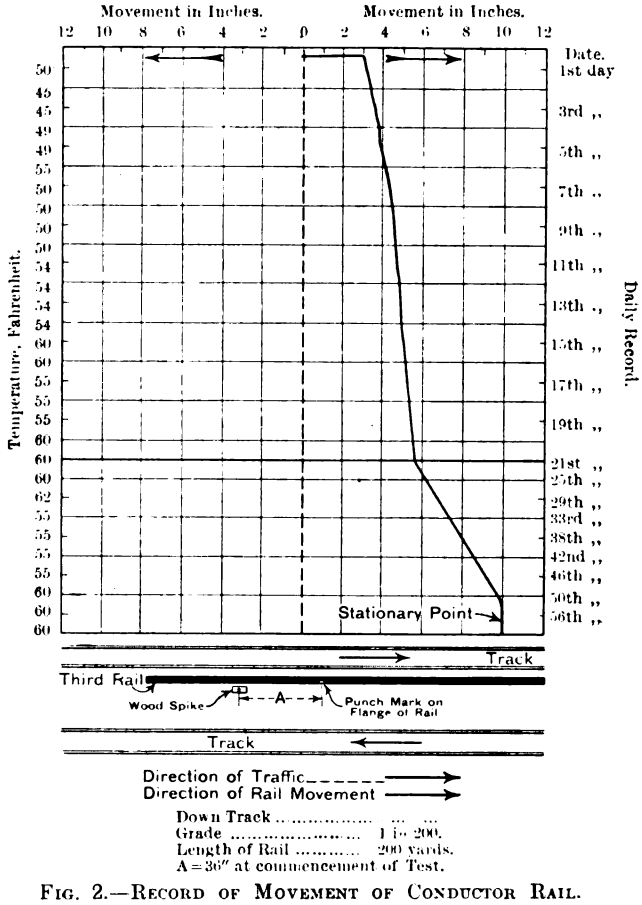

Fig. 2.—Record of Movement of Conductor Rail.

leases the tension set up in the rail (by variations of temperature), and so enables the rail to expand, and in expanding shoots forward to a new position, and this action constantly going on causes the rail to move or creep along.

Having this trouble and danger of rail-creeping to contend with, something had to be done to prevent th

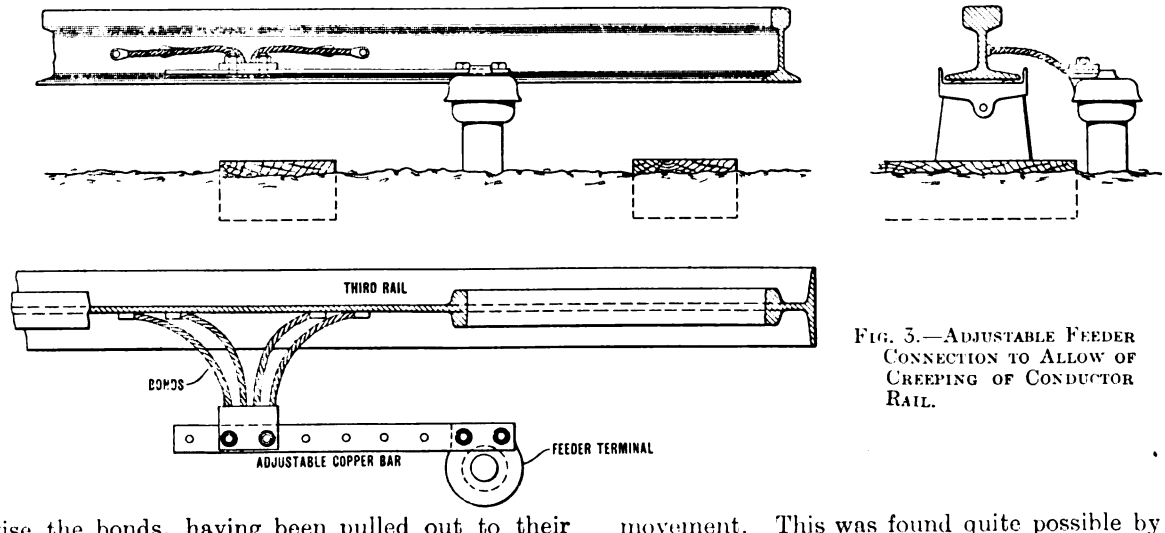

Fig. 3.—Adjustable Feeder Connection to Allow of Creeping of Conductor Rail.

otherwise the bonds, having been pulled out to their fullest extent, would have broken, or pulled the cable terminals out of the ground. An illustration of this is given in Fig. 3.

movement. This was found quite possible by allowing expansion joints every 60 yards or 100 yards, and effectually anchoring each such lengths. To endeavour to run longer lengths of rail is not advisable on account

Digitized by Google

of the strain set up at anchored points. It might be interesting to mention here that when the writer was experimenting in this connection, it was found when anchoring half a mile of rail that a pull of anything up to 10 tons was obtained at the anchor; and since the pull has to be transmitted through some forms of insulator, and at the same time must not be attached to the sleepers, it became a very difficult and undesirable arrangement. It might naturally be asked why not copy track rails and allow sufficient flexibility of bonds at each joint, so that each joint absorbs the movement of its individual length of rail. This has been tried, and it has been found that the rail creeps along and crowds up to one end, and as soon as all the joints are tight the probabilities are that it will then start moving. The dangers attendant on third rail creeping are considerable, since the run on the pieces at the ends of the rail, will, if moved to any extent, foul the track, and should the rail get out of line, the shoe will not mount the rail, but catch on the side of the third rail and tear it up, and break the insulators until the train is stopped.

RECENT IMPROVEMENTS IN RADIO-TELEPHONIC METHODS AND APPARATUS

By L. H. Walter

ALTHOUGH quite a number of patents relating to wireless telephony have recently been published, only a few present features of fundamental or even special interest. Even in the case of these, it is not easy to decide, without experimental data, as to whether the methods described constitute any material advance. What can, however, be determined is whether they have the appearance, at least, of being workable. With these qualifications in mind, one or two of the more promising arrangements may be dealt with. Taking, first of all, methods utilising the spark discharge, these present particular interest, in that, were it possible to deal with equally large amounts of energy in a form suitable for speech reproduction, as distinct from mere transmission of musical sounds, the simplicity of the arrangements would, as in the case of wireless telegraphy, ensure them a measure of popularity at least equal to that which the arc at present enjoys.

It is well known that it is possible to reproduce music by means of Hertzian oscillations with even the simplest apparatus, whilst spoken words are but imperfectly reproduced, or not at all, when the spark frequency is low, as it usually is in the arrangements hitherto described. Ruhmer has pointed out in this connection how few inventors have realised the necessity of, or made provision for, spark frequencies well above those of the harmonics involved in the complex sounds which are in the majority in speech transmission.

A method which appears to overcome the drawback to the spark methods, so far as the question of sufficient energy is concerned, is that due to E. R. Clarke and M. Barr. These inventors make use of the properties of the resonance transformer, and in particular of the fact that if the natural period of the oscillatory current in the circuit is made shorter than the period of the impressed potential difference, the circuit can be brought into tune by adding to it further capacity or inductance, as is well known. If, then, a variable (or tuning) self-inductance be included in the circuit, a proper adjustment will give a maximum length of spark in the spark-gap. In this condition the arrangement is very sensitive to any alteration in the self-inductance, a very small variation being sufficient to stop the discharge, and it is this sensitiveness to small changes of the self-inductance that the inventors propose to apply. In practice, this may be effected in two ways. In the first, an arc is placed in shunt to the tuning inductance, and adjusted until no spark normally passes at the spark-gap, but so that the least disturbance of the arc will cause the potential difference across the condenser to rise sufficiently to spark across. The second and simpler way, which the inventors prefer, consists in causing the microphone current to act inductively on the tuning self-inductance, which, in such a case, acts as the secondary of a transformer.

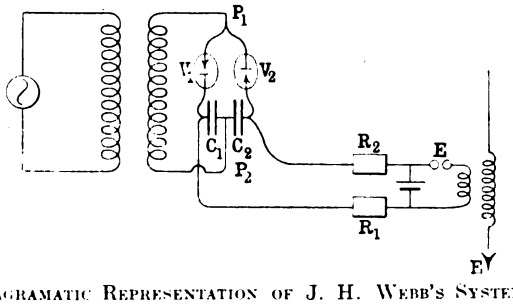
In this way a low-voltage (1 volt) microphone is said to be capable of controlling the spark-gap with great delicacy, and of enabling a large amount of energy to be dissipated by the variation of the small low-voltage microphone current.

The sparks of variable frequency naturally reproduce any musical sounds which affect the microphones, but for speech reproduction the impressed frequency of the supply current must be made sufficiently high. Though this obvious fact is stated, no information is given as to how, with these frequencies—sufficiently high to be higher than the harmonics concerned—the sparks are to be produced—a matter of some little difficulty. The arrangement thus seemingly involves, besides the use of a special alternator, a somewhat specialised arrangement for securing sparking at very high rates of speed.

The next method, that of J. H. Webb, is a spark method of transmission which aims at accelerated discharges, thus approaching the results obtained by the arc method more nearly.

The continuity of the oscillations is obtained by an application of Lodge's valve-tube storage method, and by the use of additional storage condensers of relatively large capacity. These condensers are maintained continuously charged, and only a small percentage of the therein accumulated energy is permitted to pass and charge the smaller condenser of the oscillatory circuit proper. The arrangement of the connections can be seen in the accompanying figure.

Here, C_1, C_2 are the two storage capacities, in series, and the joining conductor is connected to P_2, one of the leads of the transformer secondary. The other



Diagramatic Representation of J. H. Webb's System.

secondary terminal is connected to the other plates of the condensers, through a pair of valve-tubes, V_1, V_2, which are in parallel, but oppositely connected, so that alternate half-waves go through each to charge up the condensers, C_1, C_2. By this means, although both condensers are charged and connected in series, they are unable to discharge through the valve-tubes, so that the condenser circuit remains charged at twice the transformer secondary potential difference. One way of utilising this stored energy is to connect the two poles of the condenser, O, to the outer terminals of the storage capacities, C_1, C_2, through high-resistance conductors, such as slate rods or a water resistance,

Digitized by Google

so that only a small amount of current can flow into the actual oscillating condenser, *O*. The condition for oscillations of maximum continuity is indicated by a steady singing sound from the spark-gap, and the adjustment of the resistance and spark-gap length are made with this end in view. An alternative way of convectively transferring a small charge induced on two rotating discs of insulating material is also described.

For wireless telegraphic signals it is proposed to employ the "continuous working" method of Fessenden and to vary the period as he does, or else to vary the coupling for the formation of Morse signals. As applied to wireless telephony, a microphone is used in the manner now well known, in which it short-circuits a part of the capacity in the oscillating circuit. A certain vague similarity between the action in this method and that in the now well-known rotating disc method of sparking employed by Marconi can be traced. Both aim at the acceleration, or rather the bringing closer together, of the discharge periods, and the similarity is to some extent increased when it is considered that the Marconi method is said to work even better when the supply current is alternating instead of direct.

The method next to be described, due to E. Ruhmer, is perhaps of greater direct interest than either of the preceding arrangements, in that not only is it an arc method, which means that one is certain that plenty of energy can be obtained, but because it is, like the first one described, a trigger arrangement, or one in which a very slight amount of energy can be used to effect a large variation in a considerable amount of energy. It further has the advantage that the sounds are not merely dependent upon a *variation* of the amplitude of the oscillations, but upon the actual amplitude, since in the normal condition the arc is not emitting any Hertzian radiation. For this purpose, advantage is taken of the sensitiveness of the arc in hydrogen to changes in the current when the latter is near the critical value, *i.e.*, at which the character of the arc changes from the stable to the labile state. The main idea is that if the arc is normally supplied with a current just sufficient to give the arc the stable characteristic, a very small reduction of the main current will suffice to change the arc to the labile state, in which state Hertzian emissions take place; and, on the main current being allowed to return to its normal value, the arc changes again to the stable form, and the oscillations cease. This is easily effected by a proper choice of the electrical dimensions, and in the sensitive condition the microphone current is used to initiate the transition from the one type of discharge (arc) to the other.

The microphone current can be made to act upon the main current in the usual variety of ways, inductively, for instance, but the inventor also proposes to make it affect the electromagnets which produce the magnetic field in which the arc is placed. If these electromagnets are polarised, the microphone current may be used to diminish the intensity of magnetisation, and since the demagnetisation process is incomparably more rapid and delicate than the inverse process, this certainty seems a valuable arrangement.

The radiation of energy, using such a method, is somewhat different in form from that usual in arc methods, in which the high-frequency current is generally only modified as regards frequency or amplitude, as in the methods of Stone and Blondel; it consists here of complex groups of impulses with blank or inactive intervals, the form of each group depending on the shape of the sound wave affecting the microphone. A simple vowel sound, such as *oo*, will thus be transmitted as a series of simple groups of electrical impulses of corresponding group frequency; a more complex sound, such as the vowel *e*, will, on the other hand, be transmitted as a series of complex groups, each main group (of the frequency of the fundamental tone) being formed of several smaller groups whose group frequencies are dependent upon the harmonics. This appears to be one of the most distinctive features of the method, taken in conjunction with the fact that these groups of impulses are not mere variations of a constantly emitted radiation, if the term may be permitted. The actual arrangements required in practice are so simple that they need not be detailed. Several other patents, however, deal more fully with the special arrangements of the arc electrodes, which need be here only briefly referred to. The electrodes of the arc gap are kept at a constant distance apart by means of a new device involving the employment of travelling bands of metal (aluminium) wire passing round distance pieces, over which they are tightly stretched.

As regards detectors suitable for wireless telephony, the one most generally used has been the electrolytic. Other less recent types, which are stated to give good results, are Fleming's oscillation valve and its offspring, the so-called "Audion" of de Forest. It is, however, noticeable that though, owing to the inclusion of a local battery, the latter is much more sensitive than the original valve, and was previously described by de Forest as the detector *par excellence* for telephonic purposes, he has, in his latest experiments in Paris, been using only a multiple detector of the crystal type. Detectors of this nature are now available in great variety. Though probably Braun's psilomelane was the first, it was not till Dunwoody described his form of detector, using carborundum, and Pickard the use of silicon, that attention was drawn to what Pierce has since shown is almost a general property of certain types of crystals. Later additions to the substances employed are titanium oxide, telluride of silver, and molybdenite. The Bronk "cell" used by the Amalgamated Radio-Telegraph Co. is also a crystal type detector, and a recent detector of the Gesellschaft für drahtlose Telegraphie, though described as a thermo-electric device, seems to partake somewhat of the characteristics of the crystal type.

In this detector two metals, copper and tin, for instance, are separated by a film of copper oxide, which has to be of a certain thickness and nature, and it seems possible to regard the arrangement as in a manner analogous to the crystal rectifying type, the oxide film reproducing in some way the peculiar properties which are shown by certain surface layers of the crystals. Still more remarkable is the fact that when considerable pressure is applied, the material pressed between two metals can be so completely non-conducting as to be what is usually accepted as an insulator. Thus von Lepel finds that an insulating dielectric pressed in this way between two spherical metal surfaces forms a very sensitive detector. How far one is at present from having arrived at a state of complete knowledge as to the action in even the simplest detectors can be seen from the fact that the steel-carbon detector, which has always been classed as a microphonic self-restoring coherer device, has now been shown by Austin to be able to act as a rectifier of alternating and high-frequency currents.

A further type of detector, which, so far as at present investigated, appears to act by coherence, but, strangely enough, will not permanently cohere, is the tantalum detector recently devised by the writer. This appears to have special advantages for sound and speech transmission; further, an auxiliary source of current being employed, one is not limited to the amount of oscillatory energy received as with the crystal detectors. In these latter, taking the efficiency of rectification at 60 per cent., Pierce's highest figure, the proportion of the received oscillatory current which is available for actuating the telephone receiver is only $0{\cdot}5 \times 0{\cdot}6 = 0{\cdot}3$.

THE LOCARNO-BIGNASCO SINGLE-PHASE RAILWAY

ONE of the latest examples of a railway electrically equipped on the single-phase system is the narrow-gauge railway, Locarno - Pontebrolla - Bignasco, in Switzerland, the equipment of which has recently been completed by the Oerlikon Company. This railway is the outcome of numerous experiments made by that company on the experimental line, Oerlikon-Seebach-Wettingen. The Locarno-Pontebrolla-Bignasco line connects the town of Locarno, on Lake Maggiore, with several small towns scattered along the Maggia Valley, and is upwards of 28 kilometres in length. Many difficulties were encountered during the construction of this line, owing to the wild nature of the Maggia Valley. In some cases tunnelling was resorted to as a precaution against falling masses of rocks.

The water-power station is situated at Pontebrolla on the left bank of the Maggia river. The station as originally designed was for supplying light and power to the town of Locarno, and comprised two units of 600 h.p. each, water being taken at a point some 1,600 metres higher up the river. A canal, partly open and partly tunnelled, led to a small forebay on the right bank of the river opposite to the station. From the

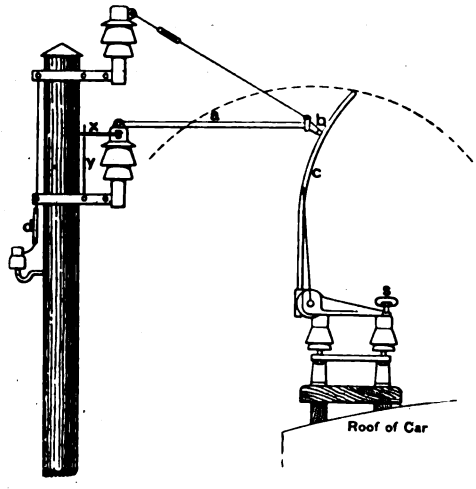

FIG. 1.—OVERHEAD CONSTRUCTION AND CURRENT COLLECTOR.

forebay, which was provided with gratings, sluice-gates, and an overflow, a pipe line, 1,500 millimetres internal diameter and some 100 metres long, led to the station below on the left bank, crossing the river on trellis girders. The effective head varied between 34·8 and 37·3 metres, according to the height of the water in the discharge pipe of the turbines. In order to cope with the demand for power made by the railway, two more units have been installed, and a second pipe-line has been laid parallel to the first. The new units, as in the case of the former, are direct coupled to spiral-type turbines running at 600 revolutions per minute, which were supplied by Messrs. Bell et Cie, Kriens. The rated output of each generator, with a power factor of 0·8, is 380 k.v.a. The generators are four-pole machines, and deliver alternating current direct to the line at 5,000 volts and 20 cycles per second. The voltage is regulated by means of a Thury regulator. The switchboard is of the most modern type, and is raised considerably above the level of the floor of the machine-room, all high-tension apparatus being beneath it in small fireproof partitions. Two main high-tension oil-switches control the sections Pontebrolla-Bignasco and Pontebrolla-Locarno.

The single overhead conductor for the line is of "Fasson wire," and has a cross-section of 50 square millimetres. It is supported on wooden poles 30 metres apart, except at crossings, and is on the left side of the line when travelling from Locarno to Bignasco. In the tunnels, however, it is suspended over the centre

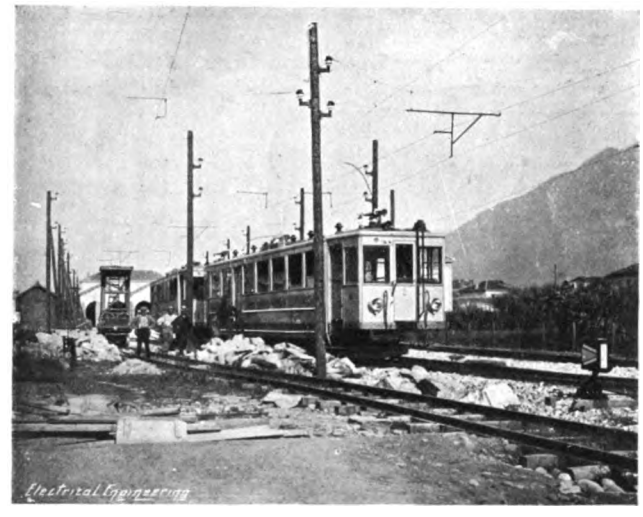

FIG. 2.—GENERAL VIEW OF CAR AND OVERHEAD EQUIPMENT.

of the track. The insulators, like those employed on the Oerlikon-Seebach-Wettingen line, are of the double-petticoat type, tested to 30,000 volts. The insulator pins are so fixed in sockets on the supporting arm as to be capable of turning. The reason for this will be explained later. The overhead conductor is divided into seven sections, each section being controlled by a high-tension switch, with horn blow-outs mounted on an iron mast. These switches act automatically, but can also be operated by hand. On the poles carrying the overhead conductor, but somewhat lower down, a 3-millimetre galvanised iron wire is carried on low-tension insulators. This wire, like the overhead wire, is also divided into seven sections, each section terminating at one of the above-mentioned section switches. Each of the high-tension insulator pins is connected to the

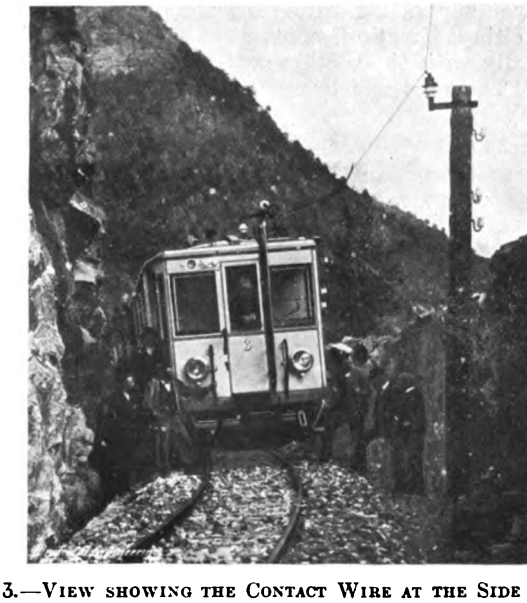

FIG. 3.—VIEW SHOWING THE CONTACT WIRE AT THE SIDE OF THE TRACK.

galvanised iron wire, as shown in Fig. 1, through a fine copper wire enclosed in an air-tight tube *d* of insulating material, the ends of which are closed by two

Digitized by Google

metal caps. In the case of an insulator breaking down, current flows through the fine copper wire, along the iron wire to the automatic switch in that section, which immediately opens, cutting the section out. Almost instantaneously the tube of insulating material contain-

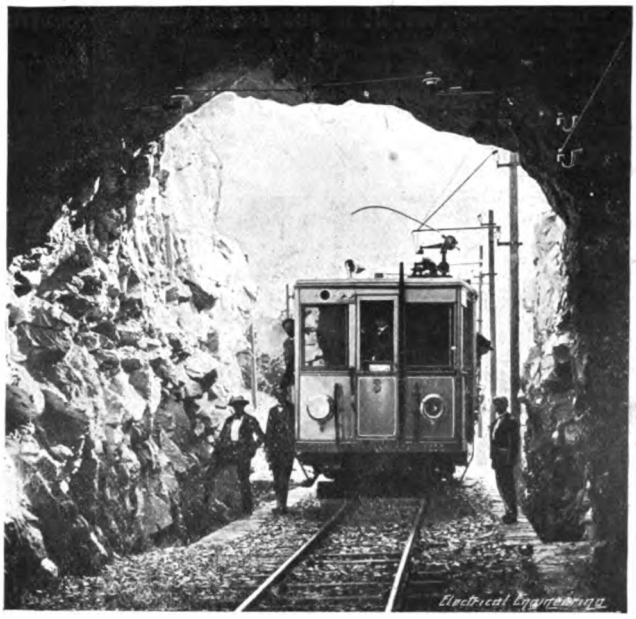

Fig. 4.—View from Mouth of Tunnel showing Suspension of Contact Wire over the Centre of the Track.

ing the copper wire explodes, owing to the expansion of the confined air, caused by the heating of the thin wire by the current. One cap remains hanging on the insulator pin and the other on the iron wire. The defective insulator is, in this way, very readily detected. The section switches are also brought into action, in case of the conductor breaking, in the following manner:—When the conductor breaks, the supporting arm a, which is attached to the metal cap of the lower insulator, swings round by reason of the tension of the conductor on the unbroken side, the insulator turning in its socket with it. Attached to the cap of the same insulator is a two-pronged wire x, between the arms of which projects a second wire-fork y, which is attached to the iron supporting arm. Upon x describing a small arc in either direction, contact is established with y, and finally with the section switch, which immediately opens. The rails which act as the return path for the

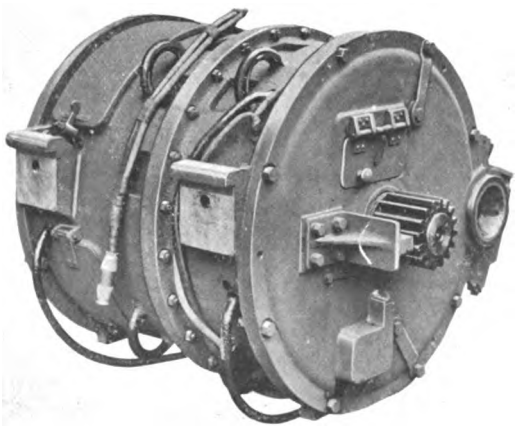

Fig. 5.—Oerlikon 40-h.p. Single-Phase Motor.

current are not bonded, but the ends and fish-plates are coated on their contact surfaces with a conducting substance before bolting together. Owing to the small current bonding was not considered necessary. The railway is being extended some distance into the town of Locarno itself, and, as may be expected, a lower voltage of 800 volts has been decided upon for that section.

Each motor-coach is provided with two distinct types of collector, one for the high-tension section outside Locarno, and one for the town section. The former

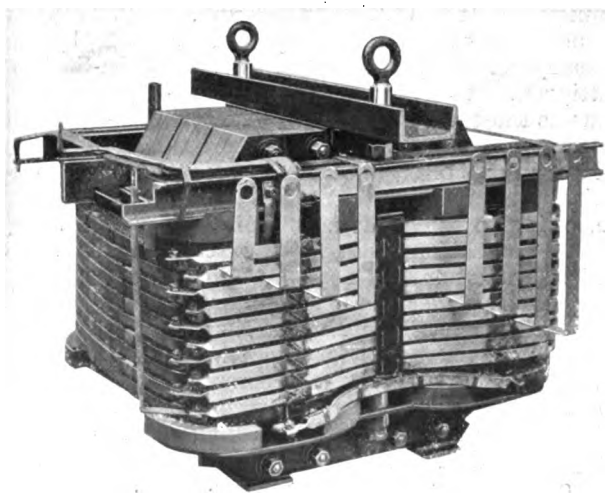

Fig. 6.—80-k.v.a. Transformer.

consists of a bent steel pipe, as shown in Fig. 1, with a replaceable strip of brass let in to make contact with the conductor. A coiled spring exerts a turning effect on the spindle to which the rod is attached, pressing the latter against the conductor with a practically constant force of about 6·5 lbs. This spring is so constructed that the pressure is independent of the position assumed by the rod in its arc of action, which embraces nearly 180°. One of these collectors is placed at each end of the car-roof, the two being connected in parallel. The extreme positions assumed by these collecting rods may be clearly seen in the accompanying illustrations. These collectors can be withdrawn from contact with the conductor, and lowered until they rest on the spring s (see Fig. 1) by means of a hand-wheel placed within reach of the motorman.

The low-tension collector is placed about midway between the two high-tension collectors, and consists of a double bow, supported on a light framework of steel tubes, the whole folding together very compactly on

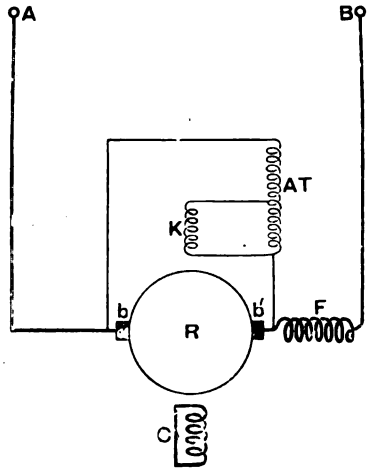

Fig. 7.—Diagram of Connections of Oerlikon Compensated Series Commutator Motor.

to the roof of the car when not in use. This collector, like the former, may be raised and lowered at will from within the car.

Digitized by Google

Up to the present the rolling-stock consists of three motor-coaches and two trailers, besides several trucks. Further additions are, however, being contemplated.

The motor-coaches are of the double bogie type, four-axled, each axle being driven by an 860 h.p. motor through 1 : 5·15 gearing. Part of the baggage compartment, which is situated about the middle of the car, is partitioned off, forming a small fireproof cell containing the fuses, oil-switches, and other high-tension apparatus. Each car has two parallel-connected oil transformers rated at 90 k.v.a. suspended beneath the floor of the baggage compartment, one on each side, in order to distribute the weight equally. On the secondary windings are eight tappings, as shown in Fig. 6, which correspond to the eight positions of the controller drum. Variation of speed is obtained by placing a greater or less number of divisions of the secondary coils in the motor circuit. On the 800-volt section of the line the secondary windings of the transformer are used as an auto-transformer.

The controllers are a modification of the usual Oerlikon type, being provided with specially large contacts and blind contacts in the intermediate positions, which may be readily replaced. On account of the heavy currents to be dealt with, powerful magnetic blow-outs are employed.

The motors are of the Oerlikon series commutator type, 200-volt, 6-pole, with compensating and commutating windings. A diagram of the connections employed for the Val Maggia Railway motors is given in Fig. 7. A, B are the terminals; F the excitation winding, which is in series with the rotor R. b b^1 represent the brushes (in all six sets). The compensating winding C is short-circuited on itself. K represents the commutating pole windings connected to the small auto-transformer A T, which, in turn, is connected across the brushes. The rotor winding consists of an ordinary 6-pole lap winding provided with equalising connections and directly connected to the commutator segments without the intervention of resistance leads.

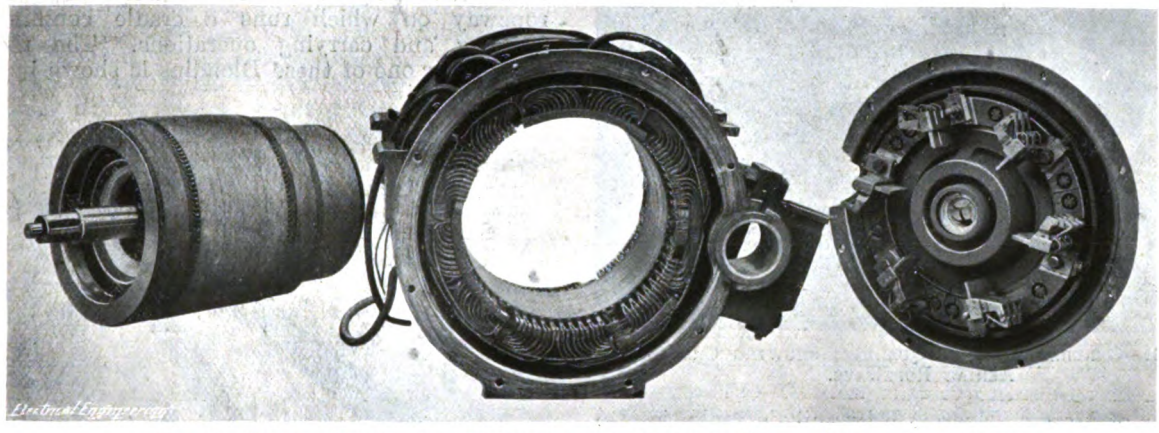

Fig. 8.—Rotor, Stator, and Brush-gear of Oerlikon 40-h.p. Single-phase Motor.

In Fig. 8 the windings of a stator are clearly shown, also the exciting and compensating coils superimposed on one another. In addition there are six small coils each embracing a single tooth, which form the commutating poles.

The cars are provided with pneumatic brakes and sand-boxes, the necessary air being furnished by two air-pumps, each connected by gearing to a motor. Air is stored in a reservoir at a pressure of four atmospheres. Lighting and heating circuits, the former at 55 volts, the latter at 200 volts, are tapped off the secondary windings of the transformers.

ELECTRIC EQUIPMENT OF RUBISLAW QUARRY

THE Rubislaw Quarry is some two miles to the west of the city of Aberdeen, and is being worked continuously for the production of a hard quality of grey granite, largely used for building purposes. The quarry is about 300 ft. deep, divided into two levels, and is about a mile in circumference. Fig. 1 is a general view of part of the quarry, showing the arrangement of the cranes on the lower and intermediate levels, and the "Blondins," or aërial ropeways, across the quarry at the surface.

The rock is first drilled by means of portable compressed-air drills, blasting charges then being inserted and the loose product hoisted either by the cranes from level to level or by the Blondins in a single operation. The larger blocks are raised bodily, while the smaller ones are hoisted in large rope baskets or nets. Until about a year and a half ago the quarry was worked by steam cranes and other steam machinery, which were supplied by a ring steam main from boilers situated at one end of the quarry. As might be imagined, the losses due to condensation in this main were considerable, and this fact, combined with a number of other considerations, such as a supply of cheap power from the Aberdeen Corporation, induced the owners of the quarry (the Rubislaw Granite Co., Ltd.) to convert the installation for electrical working. They retained as their consulting engineer Mr. Charles H. Merz, and Messrs. Siemens Bros. Dynamo Works, Ltd., were entrusted with the conversion as main contractors. This firm supplied all the electrical plant, including transmission lines, switchboards and motors, part of the mechanical equipment being sublet to sub-contractors.

Continuous current at 440 volts is obtained from the Aberdeen Corporation mains, an additional feeder having been laid down for the purpose. At the office buildings of the company at the quarry, this feeder is led to a panel fitted with a Wright demand indicator and a recording watt-hour meter. The current then passes through two circuit breakers, which control the whole of the supply, and also serve to protect the meters from a short-circuit in the event of accidental falling of the bare wires, &c., and thence by a bare overhead main on wooden poles to a controlling switchboard placed in the same house in which the large 20-ton crane motor is installed. This house is situated

Digitized by Google

at the edge of the quarry, as shown in the general view, and in a central position with respect to the various motors.

The switchboard consists of an incoming mains panel, feeder panels, and lighting panel; an earth

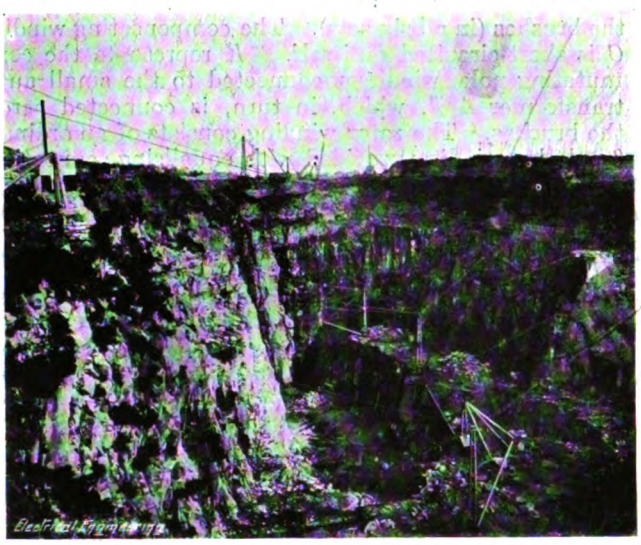

Fig. 1.—General View of Quarries showing Cranes and Aerial Ropeways.

indicator of Messrs. Everett Edgcumbe's make is also provided, so that any "earth" on the system may be readily detected and put right. This control board is connected with a ring main encircling the quarry, consisting of hard-drawn No. 000 gauge copper wire, supported at suitable intervals round the top of the quarry on insulators mounted on special brackets. The design of the latter is such that the ring main can be easily shifted if this becomes necessary in the process of quarrying. Current is conveyed from this ring main to the various motors by insulated cables, the connections being made by clamps which may be easily removed, if necessary. At the west end of the quarry it was necessary to carry the mains across a wide gap to the opposite side of the quarry. For this purpose the mains were brought vertically down the cliff a certain distance, and then run horizontally across the quarry, being supported by a number of special brackets fixed to the guy ropes of the crane. This is shown in the general view of the quarry (Fig. 1).

Altogether there are 10 cranes in operation, each equipped with a Siemens C type motor, controller and switch-box, the entire equipment being of substantial design and waterproof, as it is mounted in the open

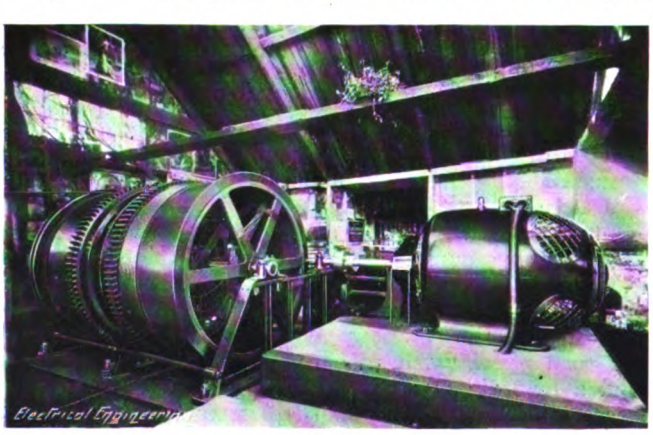

Fig. 2.—Winding Drums for Aerial Ropeways driven by 75-h.p. 440-volt Motor.

with no housing or covering whatever. The switch-boxes contain circuit breakers and fuses. The motors are series wound and of from 25 to 75 b.h.p. The largest motors are used for driving the 20-ton crane, which works on the ground surface and has a lift of 300 ft., and the four Blondins. In these instances the motors are installed in separate houses overlooking the quarry. The 20-ton crane and motor-house can be seen in the background in Fig. 3. The controllers are of Messrs. Siemens "KA" type, with "forward" and "reversing" motion with one handle, and are in all cases, except in the larger sizes, combined with their resistances, a convenient design occupying little space. The mechanical alterations to the cranes, to adapt them for electric driving, were executed by Messrs. Martin & Co., of Kelvin Works, Newcastle-on-Tyne. Each Blondin consists of a wire ropeway on which runs a cradle combining both hoisting and carrying operations. The motor and gearing for one of these Blondins is shown in Fig. 2.

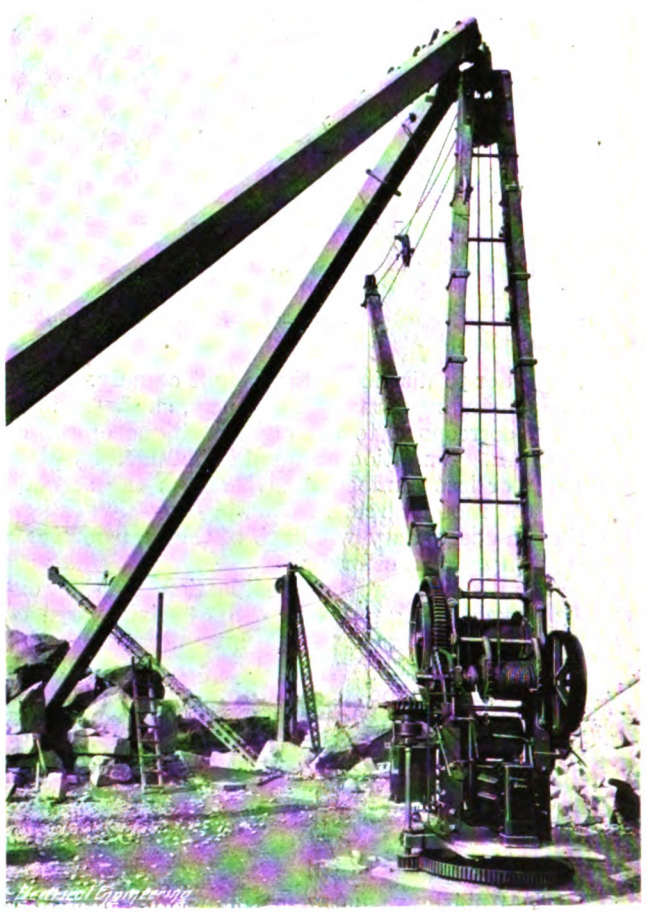

Fig. 3.—15-ton Electric Crane, with 20-ton Crane in Background.

The plant further includes two centrifugal pumps, driven through flexible couplings by Siemens motors. Both pumps are installed at the foot of the quarry, and are capable of lifting 7,500 gallons of water per hour through an 8 in. main against a head of 300 ft. Provision is made for an extra 100 ft. at a future date. The motors are of 25 b.h.p. each, and run at 1,200 r.p.m. The cable feeding these pump motors is led direct from the control board down the cliff, being fixed to the 8 in. water main. There is also a very complete compressed-air system, including an Ingersoll-Rand compressor driven by a Siemens 104 b.h.p. motor. The air is carried by a ring main round the quarry to receivers at suitable points, from which it is taken to the various drills. A very complete stone-breaking and crushing plant has been installed by Messrs. Baxter, of Leeds, the crushers, rotary screens, and fine rolls being driven by motors ranging from 18 to 40 b.h.p.

ELECTRICITY IN MINES

Reports of H.M. Inspectors of Mines

THE reports of H.M. Inspectors of Mines for the various districts into which the country is divided for colliery inspection purposes contain, amongst other matters, a good deal relating to the uses of electricity in mines, especially as regards accidents attributed to electrical causes, and in many of these reports it is shown how greater care and stricter observance of the Home Office rules for the use of electricity in mines could have avoided fatalities. The number of electrical accidents reported is trivial in comparison with those due to other causes, but it is none the less important to investigate such as have occurred and consider the means by which similar accidents can be avoided. An extensive digest of the collected reports is given in the *Colliery Guardian*, from which portions of the reports are abstracted.

In the Swansea district Mr. J. Dyer Lewis reports one fatal accident due to the use of electricity underground, in which a workman was killed in consequence of a leakage of electric current due to a fault in a switch-box A small 6 h.p. power motor, drum, and other fittings appertaining to a haulage gear, were erected above the railroad upon a platform of steel girders built into the sides of an archway. Current was supplied by a three-phase alternating plant, periodicity 48, and 550 volts pressure. Armoured cables fixed to the sides of the shaft, conducted the current down a pit, and junctions were arranged for a supply of power to a pump erected in a room cut into the side of the shaft, about midway between top and bottom, for another large pump at the pit bottom, and for the haulage motor. The electrician considererd that the contact of the girders with the strata efficiently earthed the haulage motor and its fittings. He had tested the earthing, and had found it absolute. The motor had been working a quarter of an hour before the accident occurred, and the motor man was at his post, when a connection in a switch-box blew out. The platform was soon "alive," and the motor man was pitched from it, and fell upon a coal-laden tram which was on the roadway beneath. The current appeared to have been conducted along a steel haulage rope suspended on sheaves at the side of the roadway, for about 200 yards to a terminal sheave, and returned along the rope lying on the floor of the heading, which was very wet for a considerable distance. A fireman, who happened to be about 80 yards away from the motor, was the first to feel a shock, and called for help. Several men came to the rescue, and one of them upon gripping the rope became unconscious. The current having been switched off at the pit bottom, the injured man never regained consciousness. An earth wire of copper was subsequently attached, and conducted any leakage to the sump at the shaft bottom.

Mr. J. S. Martin, the inspector for the Southern district, also records a single fatal electrical accident. This occurred at the Ebbw Vale Company's Marine Colliery. An underground electrical haulage engine operator received a fatal shock at an intermediate haulage engine station, between the shaft and another haulage engine station further inbye, nearer to the faces, while twisting one of the lighting cables around an insulator in order to take up slack. The lighting current for the engine-room and vicinity is provided from the power plant at 540 volts. There is a make-and-break switch provided with two fuses which blow at 1 ampère. Breakages of the cable appear to have been not infrequent from one cause or another, and they were repaired by whoever was at hand, twisting the wires together without covering them at such points. Gloves, although provided, do not appear to have been worn very regularly on these occasions. On April 24, the day before the accident, a journey rider made a joint as described and left the wires uncovered, so that deceased, not having cut off the current or used gloves at the time of winding up the cable, came in contact with the bare wires and got a shock, which proved fatal, as no one present knew how to render first aid. The electrician, although aware that breakages were frequent, had provided neither rubber nor tape to cover these joints of repair, nor does he appear to have given it the personal attention he should have done, and which was expected of him. He has since been superseded. A shaft fire, due to electrical cause, was reported at the Marine Colliery in the same district. Here the separation doors between the shafts were found to be on fire in consequence of an electric cable having short-circuited where it was carried through a hole in the side and close to the frame of the door, upon which it evidently had rested, contrary to Section VII. (2) of the Electrical Special Rules. The cable, a well-insulated one, must have been rubbed in some way to cause it to fail at this point. It being a fiery mine, and the fire being adjacent to the return air, the result might have been serious. Mr. Martin remarks that electricity continues to be developed at the mines in this district for haulage and pumping purposes. The newer mines in Monmouthshire are being laid out with a view to large generating plants. It has also extended in the Forest of Dean collieries, in which section of the district is situated Trafalgar Colliery, the pioneer of electricity in the mines of at least this district and the South Wales coalfield. Bristol and Somerset have also got small installations at some of the mines.

The report of Mr. Robert McLaren for the East Scotland district mentions one fatal accident due to the use of electricity, which, as will be seen from the following account, would have been avoided by the exercise of reasonable care. The accident occurred at Bowhill Colliery, Fife. The system is alternating, with voltage of 500, three-phase, and the cable is armoured. In the Lochgelly Splint Coal dook a three-throw pump had been started a few days prior to the accident. While the motor was in motion deceased attempted to put in some flooring under the cable, and raised it, with a piece of iron to lever it up, with the result that the sharp end cut through the insulation, making the piece of iron "live," and causing the full current to pass right through the man. The motor was properly earthed.

The same report also contains a note on the prosecution of a mine manager for contravention of the electrical rules. In this case, which occurred toward the end of 1906, a miner was killed by an electric coal-cutter becoming "live," and the current, passing up the haulage rope, came in contact with the man. The cause of the motor becoming "live" was due to a defect in the bushing, and proceedings were sanctioned for contraventions of (1) Section I., rule 11, failure to employ a competent person; (2) Section I., rule 1 (*a*) and Section III., rule 30, failure to have trailing cable in connection with coal-cutter heavily insulated and effectively covered throughout; and (3) Section I., rule 1 (*a*) and Section V., rule 35, failure to have holes in motor casing substantially bushed with insulating bushes. The person employed to look after the electric plant had no technical knowledge of the subject. The trailing cable consisted of a cable covered with insulation, and having an outer covering of plaited leather, and, in the opinion of Mr. Ram, the electrical inspector for the Factory Department, the internal insulation was too light, and did not comply with the terms of the rule, "heavily insulated," and the bushing consisted of a brass ring countersunk into the motor casing, and through this bushing the bare cable, inside an indiarubber tube, passed into the motor. The defence, which was taken up by the makers of the motor and cables, was that the person in charge was competent, the trailing cable was heavily insulated, and the india-rubber tube was an insulated bush. The Sheriff took the case to avizandum, and subsequently convicted on the third count, and found the other counts not proven.

Mr. Ronaldson's report for the West Scotland district mentions a case where a man was killed by electric shock in the

Digitized by Google

Polmaise Colliery. The shaft bottom was lighted by incandescent lamps arranged two in series, the current being taken from the power cable, and the conductors were placed inside iron tubes earthed by being connected to the armour of the shaft cable, which in turn was connected to the sole-plate of the dynamo on the surface. The electrical supply is alternating, with a voltage of 500 and a periodicity of 50. The deceased and other two men observed electric sparks passing between the tube containing the lamp leads and an iron beam with which it was in contact. The deceased went to the switch close at hand to cut off the current, and, on touching it, received a shock which caused his death in about 15 minutes. Apparently the iron tube in which the leads were enclosed had become temporarily live. Owing to alterations being carried out at the shaft bottom, the tubing in which the leads were enclosed was not joined directly to the armour of the shaft cable, but was temporarily connected with it by a piece of steel rope. There must have been some defect in the earthing arrangement. Two non-fatal accidents by electric shock were reported. The first occurred to a roadsman who was handling a live cable at a switch-box, and the second occurred to a drawer, who got his hand severely burned by taking hold of a cable, the insulation of which had been cut through by a fall of roof.

Mr. R. Donald Bains' report for the Durham district gives particulars of two accidents caused by electricity, resulting in the deaths of two persons and injury to another, and three accidents by which three persons were more or less injured. Both the fatal cases occurred in connection with coal-cutting machines; the first at Burnmoor Colliery, and the second at Lumley Colliery. Both collieries belong to Messrs. the Lambton Collieries, Ltd. The accident at Burnmoor caused the death of the master shifter and injury to the machineman. The machine was of the bar type mounted on skids, and driven by an alternating-current 500-volt motor of 30 h.p. The current was taken to the motor from the gate-end switchbox by means of a trailing cable, fastened down to the side of the machine by means of a piece of hemp rope. By this means, so long as there was slack cable behind the machine, the cable is kept from being squeezed between the timbers supporting the roof and the machine. This piece of rope was, shortly after the accident, found cut in two, and the cable jammed tight between a chock and the projecting bracket on the framework of the machine, and one of the conductors laid bare. The cause of this was that, contrary to Section V., rule 7, of the Special Rules for the Installation and Use of Electricity in Mines, it was being dragged along by the machine, and was in consequence taut. The squeezing off of the insulating material, and the consequent contact of the bare conductor with the machine, electrified the machine itself, the hauling rope already referred to, and the ground in the immediate vicinity. The man attending to the machine had not been aware of what had occurred, and was in the act of working a ratchet lever to adjust the height of the machine, when he received a shock and was thrown down between the machine and the face. There he stayed, not daring to move, but shouting for help. The master shifter came forward, but received a shock and was thrown down. His lamp was extinguished, and he then turned and crawled along the face, with the intention of reaching the gate-end switchbox to switch off the current. Crawling in the dark he touched the hauling rope, and from it received a fatal shock. Other men, hearing the machineman shouting, hastened to the gate-end box and switched off the current. The machine attendant had also received a shock, but not a fatal one. There was in the trailing cable an earth return. The method of connecting the earth return to the frame of the coal-cutter was by means of a pin, on which was a collar. The end of this pin was threaded to screw into a hole in the coal-cutter frame, and it was intended that on the pin being passed through a brass plate, to which the earth return wire was soldered, the shoulder, or collar, should press against the brass plate and so make a connection. As a matter of fact, the hole in the machine frame was not big enough to allow of the pin being screwed deep enough to permit the collar on the pin to touch the brass plate. The side of the pin, however, would, in all probability, touch the inside edge of the hole in the plate as it passed through, but this would not make a firm contact or connection. The trailing cables were in lengths of 70 yards. These lengths were joined together by specially arranged junction boxes, which were so made that the connection between the earth return carried in each length of trailing cable was not automatic, but had to be made by placing in position an iron bridge-piece. Further, it was easy for this bridge-piece to be so placed as not to connect the earth return in each length of trailing cable.

In the present instance, Mr. Bain thinks that the earthing of the coal-cutter motor (which, being a portable motor, is not required by the Special Rules) was inoperative; and that this was due either to the connection direct to the frame of the machine being faulty, or to a bridge-piece connecting two lengths of earth return in the trailing cable not being in its proper position. The direct cause of the leakage of current was the fact that the trailing cable was allowed to be dragged along by the machine, and, as a consequence, was squeezed between the coal-cutter and a chock, and the insulating material thereby scrubbed off one of the conductors. Since the accident steps have been taken to make the passage of the trailing cable along the face as automatic as possible, and to so arrange the junction boxes in the trailing cable that the connections of the earth return cannot possibly be otherwise than correctly made. The second case was very similar to the above. A conductor in the trailing cable became exposed, and caused the machine to be electrified. The machineman received a shock and died. Of the three non-fatal cases, one occurred at Langley Park Colliery, belonging to Messrs. the Consett Iron Co., Ltd. A man received a slight shock by touching a cable, the insulation of which had been cut through by a fall of stone. The second case occurred at Newbottle Colliery, belonging to Messrs. the Lambton Collieries, Ltd., and was due to a leakage of current from the trailing cable of a coal-cutting machine. The last case occurred at North Biddick Colliery, belonging to Messrs. the Lambton Collieries, Ltd.

Two explosions, which were due to the use of an unenclosed motor in certain circumstances, are mentioned in Mr. W. H. Pickering's report on the Yorkshire and Lincolnshire districts. These occurred at Westgate Colliery, belonging to Mr. Henry Ellison, of Cleckheaton. The motor was attached to a pump. The engineman omitted to switch the current off from the pump motor when he came out of the pit shortly before he started the fan. Had he done so these two explosions would not have occurred. At it was, in starting the fan, and leaving the open-running motor with the electric current on it, he did exactly what was required to cause the first explosion, for to get to the air pipes the gas had to pass the sparking commutator of the motor. On Mr. Walker making an inspection and investigation of the circumstances, he found that no less than nineteen of the General Rules of the Coal Mines Act and Electricity Special Rules had been violated. Convictions were obtained and substantial penalties inflicted.

Mr. H. Hall's report on the Liverpool and North Wales district does not record any accidents traced to electrical causes, but makes a few general remarks regarding electrical working in mines. He does not apparently regard electrical coal-cutting with much favour. He considers that it is remarkable how quickly the persons put in charge of electrical machinery grasp its details and dangers, and are thus able to handle it with safety. Mr. Hall would have preferred that the Electrical Special Rules should have required the precautions against the ignition of fire-damp to be enforced throughout every part of a mine where safety lamps are in use instead of only to such parts where General Rule No. 8 applies. A considerable increase in the use of electric power for hauling and pumping in this district is recorded.

Three accidents in which electrical working was concerned are reported in the Midland district, and commented on by Mr. A. H. Stokes. In one of these a boy travelling along a roadway touched an electric cable at a place where there was a minute hole in the insulation, which accounted for the leakage, and, as the roadway was wet, he received a shock and his hand was burned. Another accident occurred to the enginewright while testing for leakages of current by means of the leakage indicator. Having pushed over the arm of the switch, a strong "earth" was discovered, and when moving the arm back to the neutral point (before disconnecting the switch), the current followed the movement of the switch and brought his hand in contact with the arc thus formed. He should have temporarily cut out the indicator when he found the leakage. Another accident occurred to the motor driver in the mine when a heavier train than usual was being drawn up the incline from the workings. At a steep part of the roadway it caused too much overload to be put upon the motor, and as the driver was standing with one hand on the controller and the other on the clutch gear, he received a slight shock. Four cases of danger from electricity have been reported during the year, all of them due either to abraded cables or defects in the earthing of the current. Considering the extensive use now being made of electricity for motive power under varying conditions, Mr. Stokes thinks this record is highly favourable, and bears testimony to the value of the new special rules for ensuring safety.

Mr. H. Johnstone, in his report on the Staffordshire district, speaks of one fatal and one non-fatal accident by electricity, resulting in one death and injury to one person. At Littleton Collieries, South Staffordshire, a lad was in charge of a 9 to 10 h.p. 500-volt continuous-current haulage motor, fitted with a double-pole switch, and a controller of the tramway type. Wishing to slack out a yard of rope, he moved the controller to the first contact, but it failed to act, owing, as subsequently transpired, to the spiral wire of a resistance coil having broken behind an insulator. He then moved the controller to the second contact, when the motor began to race. He shouted to a fireman who stood near that something was wrong, and presumably threw his hand back to pull out the switch which was behind him. From the burns upon the back of his hand and forearm, his hand appeared to have come in contact with the uncovered blades of the switch, and he had then fallen against the heated resistance coils. He was killed instantly. The motor had been installed a considerable time prior to the establishment of the special rules for the installation and use of electricity in mines. Availing himself of the powers con-

Digitized by Google

ferred upon him by Rule 55, the inspector directed that this and all similar switches in the mine should be enclosed or otherwise covered, and this has since been done. At Sneyd, North Staffordshire, on June 11th, an electrician received a severe shock on touching a main junction box situated close to shaft bottom. The current was 440 volts, three phase. A leakage was known to exist, there being a dead earth on one phase, and the junction box referred to was opened while endeavouring to locate it. It was traced to a badly-made joint at the screens, which led to the armouring of the cable becoming live. Fortunately no serious results ensued. One or two cases of failure of insulation causing "dangerous" occurrences are also mentioned in the same report, and the following accident in the Florence Colliery, North Staffordshire, is mentioned. A blower of gas under the holing at a longwall face was ignited by an arc caused by a breakdown of the insulation on one of the field leads of an electric coal-cutter, an earth on the surface having occurred at the same time. Fortunately, there was no accumulation of gas, and the burning blower was promptly extinguished by the machine chargeman.

In Mr. F. A. Gray's report relating to the Cardiff district, it is stated that only one accident occurred through the use of electricity, and the injured cause was very slight. At the National Colliery a new three-phase 250-h.p. haulage motor was being tested by the colliery electrician and the electrician of the firm who supplied the plant. The voltage was 550. A spare panel on the switchboard was used for the test. The colliery man said he left the controller handle in the off position, and went and put in the switch, when, to his surprise, the rotor of the motor began to revolve, and the ammeter registered 100 amperes. This could not have occurred until the controller handle was put in the on position unless there was short-circuiting in the controller. The firm's electrician called out "stop," and as the colliery man drew the switch back there was an extensive arc or flash which burned him on the face and hand. The controller handle was found to be in the on position after the accident, and after a test was made of the controller it was found to be free from electrical defect. On account of this accident, and until this and the other switches are altered, it was decided that in no circumstances is one of the panel switches to be put in or out until the bus-bars are made dead by taking out the main switch, which breaks under oil.

In the same report a very remarkable case is recorded of damage in a mine due to lightning. At Nantgwyn Colliery, during a severe thunderstorm, the headgear was struck, and the discharge descended the pit, nearly 500 yards deep, by the guides and haulage ropes. At the pit bottom the master-haulier, who was handling the main haulage rope, received a shock which knocked him down. He said he saw a flash of light running along the rail. A shackler, who was in the "slum" near the shaft, had one hand resting on a tram, and the other on a wrought-iron pipe, received a shock, and saw a large flash of blue light, which he said lit up the place like daylight. The hitcher saw flashes on the guide ropes. The current passed in along the haulage rope in the 6 ft. seam about 600 yards, where a haulier said he saw greenish-coloured sparks given off from the tail rope, which was not moving. It also travelled in along the haulage rope in the 9 ft. seam for a distance of 485 yards, where several sparks were seen, and both there and in the 6 ft. seam a sound resembling the exploding of a squib was heard. All the electric lights on the surface were put out, and the fuses had to be renewed. Since this occurred lightning conductors have been attached to all the pit headgears of this colliery.

ELECTROLYTIC PRODUCTION OF COPPER TUBES, SHEETS AND WIRE

MR. S. O. COWPER COLES read a Paper at the Bristol meeting of the Institution of Mechanical Engineers, in which he described the "centrifugal" process for the direct electrolytic production of copper tubes, sheets, and wire.

The refining of copper by electrolysis has now assumed vast proportions, and the annual output of electrolytic copper in the year 1907 has been estimated at 400,000 tons, equal to 56 per cent. of the world's production, and the capital sunk in the industry at about £15,000,000. The whole of the copper thus produced is in the form of rough slabs or cathode plates which have to be smelted and worked to the desired forms. Electro-metallurgists have been striving for many years to devise a process which does away with the smelting of copper after it has been electrolytically refined, and to electro-deposit copper after the refining operation in such a form that it can be placed direct on the market as finished tubes, sheets, and wire.

It was observed shortly after Elkington practically applied Faraday's law to the refining of copper in the year 1865, that the current density, or the rate at which the copper is deposited, could be considerably increased by circulating the electrolyte or moving the electrodes. Wilde was one of the first to use a cylindrical cathode, his object being to deposit copper on iron rollers for textile printing purposes, for which he took out a patent in the year 1875. The anodes consisted of copper cylindrical tubes, and the iron cylinder to be coated with copper (the cathode) was placed in the centre of the cylindrical vat and caused to rotate on its axis. The next development of importance was the Elmore process, which consists of using horizontal mandrels on which copper sheets or tubes are deposited, while agate burnishers travel continuously over the copper, so as to consolidate it, and to prevent the growth of copper trees or nodules. Even with the use of a burnisher, however, the current density cannot be increased beyond 30 amperes per square foot. Dumoulin introduced, at a later date, a process for burnishing copper during deposition with sheepskin, and claimed that the process had also the advantage of insulating any projections that might be formed by coating them with a thin film of animal fat, thus preventing further deposition until the surrounding depressions are raised to the common level. It was claimed for this process that a current density of from 30 to 40 amperes per square foot of cathode surface could be employed at a voltage of about 1·6 per vat. This process was tried on a large scale in England, but was soon abandoned. Attempts have been made at various times to further increase the rate of deposit by Swan, Elmore, Thofehrn, Graham, Poore, and others, by impinging jets of the electrolyte against the cathode surface.

The author, when carrying out some experiments on the production of copper tubes and sheets by electro-deposition on rotating cathodes, observed that when the speed was greatly increased entirely new results were obtained, and that a current density of 200 amperes or more per square foot could be employed, the copper remaining smooth and having a tensile strength equal to the best rolled or drawn copper. This observation led to further experiments, which resulted in evolving the process now known as the centrifugal copper process for the manufacture of sheets, tubes, and wire.

After a long series of experiments had been made to determine the best composition for the electrolyte and the most economical current density to employ, the critical speed was accurately determined by means of revolving cathodes in the form of cones; and by observing the point at which the copper remains smooth, 200 amperes per square foot was found to be the most economical current density.

One of the chief difficulties inherent in any electrolytic process for the production of copper tubes and sheets is having any working parts, such as bearings, in an acid solution. This difficulty was eventually overcome by constructing vats in the form of an annular ring. By such an arrangement all working parts are outside the vat and do not come into contact with the electrolyte, so that the bearings can be lubricated in the ordinary way. The cathode consists of a steel or cast-iron cylinder closed at one end, to which is attached on the inside a steel rod projecting below the edge of the mandrel to guide it into position; the cylinder can be 5 or 6 ft. in diameter, or even larger, so as to produce a copper sheet of, say, 20 ft. long by 4 or 5 ft. broad. Anodes composed of crude copper are placed around the mandrel with intervening spaces, and are fed forward by suitable mechanical means, as the copper dissolves away, so as to keep the voltage constant.

One great advantage of the centrifugal process is that a very low voltage is required even when employing a very high current density; for instance, only 0·8 of a volt is required at the terminals of the vat when working at a current density of 200 amperes per square foot of cathode surface. The effect of revolving the cathode is five-fold; first, it keeps the electrolyte agitated, so that there is always a fresh supply of copper ions in proximity to the cathode; secondly, each molecule of copper as it is deposited on the cathode is burnished or rubbed down by means of the skin friction between the revolving cathode and the electrolyte; thirdly, the rotation prevents any foreign matter that may be in suspension in the electrolyte settling on the cathode and becoming entangled by further copper being deposited around or over it; fourthly, it brushes away any air-bubbles on the cathode, which are the cause of nodules forming; and, fifthly, the rotation of the cathode ensures the thickness

Digitized by Google

of copper being uniform, even when a mandrel of, say, 8 ft. in length is employed.

The method of making tubes by the centrifugal process is as follows :—A mandrel somewhat smaller than the finished internal diameter of the tube is prepared by coating it with an adhesive layer of copper by first depositing copper upon the surface from alkaline solution and then thickening it up in an acid solution, the surface being highly burnished and treated chemically to ensure the easy removal of the deposited tube. The mandrel thus prepared is then placed in a vat. When the desired thickness has been obtained the mandrel is removed and placed in a horizontal or vertical lathe, and a round-faced roller run over the surface so as slightly to expand the deposited copper, which can then be readily drawn off. Copper sheets are prepared in a similar manner, the only difference being that the mandrels are of much larger diameter, and a narrow insulating strip is fitted down one side so that the sheet can be easily removed by inserting a tool under one of the edges of the deposited copper. It is no more costly by the centrifugal process to make thin sheets than thick ones; copper foil can be made in five minutes direct from crude copper.

Copper tubes produced by this process without any drawing have given a maximum stress of 17 tons, and tubes after drawing have withstood a pressure of 3,000 lb. per square inch without showing any signs of distress.

Sheets made without any rolling have given a maximum stress of 28 to 30 tons and more per square inch, according to the peripheral speed at which the mandrels were revolved. The formation of copper trees and nodules was another difficulty that had to be overcome, but which has been reduced to a minimum in the centrifugal process, for the reason that impurities held in suspension in the electrolyte have no opportunity of settling on the cathode, and all gas-bubbles are swept from the surface on which the copper is being deposited.

The production of copper wire by electrolytic means is a more difficult problem than the production of copper tubes and sheets. Various processes have been suggested and tried from time to time such as the electro-deposition of copper on thin wire, until it has obtained a considerable thickness, and then drawing the thickened wire down to a comparatively fine wire. Swan and Saunders have both experimented with such processes, but so far they have not been worked commercially. Elmore's process consists of producing copper tubes by his burnishing method, cutting them into long spirals and then drawing them into wire. Other experimenters have tried placing an insulated spiral strip on a cylindrical mandrel so as to produce long copper spirals, but such an arrangement only allows of a very low current density being employed, on account of the nodules which form on the edges of the strip, even at very low current densities, rendering the strip unsuitable for drawing down into wire.

Copper wire is made by the centrifugal process in the following manner :—A mandrel similar to that used for making copper sheets is employed, around which a spiral scratch is made, the pitch being determined by the size of wire required. The effect of the spiral scratch (which need only be very light, but must be angular), is to cause the crystalline structure of the copper to form a cleavage plane. The copper divides exactly at the apex of the scratch, that is, the copper deposited in the scratch is equally divided and forms a small V-shaped fin on two sides of the copper strip. If the scratch is not angular, but rounded at the base, the copper will not divide, as the crystals are radial. After the desired thickness has been obtained, approximating the pitch of the spiral scratch, the mandrel is removed from the depositing cell and placed in a vertical position on a lathe, and the copper strip is unwound at an angle of about 45° to the face of the mandrel. During the process of unwinding the small fin or burr is removed by passing the wire through a suitable die and then through a wire-drawing machine provided with three or more draw-plates to reduce the strip to the desired diameter. By employing a mandrel of 6 or 7 ft. in diameter, lengths of wire four or five miles long can be made in one operation.

ELECTRICAL EQUIPMENT OF THE OTTAWA MINT

A PAPER read recently before the Canadian Society of Civil Engineers by Mr. A. H. W. Cleave, and reported fully in the *Canadian Electrical News*, describes the mechanical and electrical equipment of the Ottawa branch of the Royal Mint. Power is supplied to the Mint in the form of two-phase alternating current, at a pressure of 2,140 volts, and with a frequency of 60 cycles. There are three transformers for the power load, and three for the lighting, two in use, and one spare in each case. They are single-phase, oil-insulated, self-cooled transformers. The power transformers supply a motor-generator with two-phase current at a pressure of 500 volts. Their normal rating is 100 kw. each. The transformers for the lighting are rated at 15 kw. each, and have a secondary pressure of 214 volts. The motor of the motor-generator set is a two-phase, 225-h.p. motor, running at 800 r.p.m. The generator is a 150-kw. compound-wound continuous-current machine, generating at 225 volts. There are in all 32 compound-wound, continuous-current motors in use in various parts of the Mint, ranging from 1 to 30 h.p. The power circuit is on the two-wire system, and the lighting circuit on the three-wire system: all wires are run in steel conduits. There are 415 16-c.p. 102-volt incandescent lamps, and 17 arc lamps. The latter are alternating-current enclosed lamps, taking 7 amps. each at 102 volts. The buildings are supplied with an efficient telephone system, and electric clocks and bells are also provided.

The machinery in the die department consists of a die-sinking press, two die-turning lathes, and a die-hardening furnace. The press and lathes are driven by a motor through an overhead shaft. In the die-press the blow is given by a heavy flywheel, 5 feet in diameter, which is keyed to a triple screw of 6 in. diameter. The flywheel is rotated by two rapidly revolving discs, which can be brought into contact with its leather-covered rim. One friction disc raises, and the other depresses the screw. Each coinage die requires three blows from this machine before the impression received is sufficiently sharp in all its details. After each of the first two blows the die is annealed in the furnace. After the third blow it is turned to the correct size, and then hardened and tempered. It is usual for a pair of dies to strike about 80,000 pieces before they are unfitted for further use. In the machine shops grinding, drilling, milling, and planing machines are installed. One 14 in. by 72 in. Norton roll-grinding machine and a Bertram planing machine have individual drive, but the smaller machines are driven in groups from shafting. Other machines in the blacksmith's and carpenter's shops are electrically driven. The furnaces in the assay department are heated by oil-fuel in conjunction with an air blast from electrically-driven blowers. In the coining department each rolling mill is driven by its own motor, through gearing. The motor, gearing, and roll housings are all on one bedplate, thus ensuring rigidity and perfect alignment. The first motion shaft carrying the driving pinion runs in its own bearings, and, at one end, is connected with the motor through a flange coupling outside one of the bearings. The driving pinion is situated between these bearings, so that the motor is entirely free from any thrust. At the other end of this shaft, outside the other bearing, a small flywheel is keyed. The second motion shaft gears with the shaft driving the bottom roll, and this latter shaft gears through double helical gearing with the shaft which drives the top roll. The rolls are connected with the gearing by means of breaking spindles and muff couplings. The couplings are held up to their work by adjustable wood distance pieces. The motors run at 600 revolutions per minute, and the rolls at from 40 revolutions per minute for the breaking down mill, to 60 revolutions per minute for the finishing mill.

The breaking-down mill is driven by a 30 h.p. motor fitted with an overload release, which is set to cut out at 50 per cent. overload. The distance between the rolls is regulated by means of worms and worm wheels actuating large, single, square thread screws of half-inch pitch. There are 50 teeth in each worm wheel. The worm shaft is divided in the centre, the halves being connected by means of a friction coupling, so that when it is necessary to "parallel" the rolls, one end only of the top roll may be moved at a time. This worm shaft is actuated by hand wheels at either end, one complete revolution of which closes or opens the rolls 0·01 inch. The hand and worm wheels are fitted with indicators and divided circles, so that adjustment of the rolls can be made as fine as 0·0005 inch. For ordinary rolling it is usual to work to 0·001 inch at this mill. The thinning mill is driven by a 20 h.p. motor, in the same manner as the breaking-down mill. The rolls in this mill are 12 in. in diameter, and 14 in. in length, and are driven at 50 revolutions per minute. The finishing mill is driven by a 10 h.p. motor. There are three cutting machines, each driven by a separate motor, and capable of cutting blanks for all sizes of coins, at the rate of 300 per minute. The coining presses, of which there are three, are of the type in which the pressure is given to the coins through levers and toggle joints. The hard

Digitized by Google

steel knuckles of the toggle joints are of exceptionally large dimensions, so that coins can be struck at the rate of 100 per minute without any danger of them becoming overheated. Each press is driven by its own motor, and arranged so that the drive can be made either through a belt or gearing. The number of blows struck per minute can be varied from 30 to 100 by means of a five-step controller. Other electrically-driven machines are the copper tumbling barrel for cleaning the blanks before they receive the impression from the dies; the overlooking machines or travelling bands, on which the coins pass before an inspector; the defacing machines for destroying faulty coins; counting and bag-filling machines, and various other pieces of apparatus. A refinery will shortly be erected in connection with the Mint, in which gold will be treated by the electrolytic process.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN the *Chemiker Zeitung* of August 5th, Professor H. Stockmeler contributes an article of considerable interest upon "Advancement in the Chemistry of Metal Working and its Various Branches." The article is to be continued, and the present portion deals mainly with metallic depositions and the various improvements in the electrodes used and the electrolytes employed.

One of the most important points which always has to be considered by electro-platers is the removal of all traces of grease and impurities on the electrode. Of late it has become customary to remove grease by electrolytic means. The articles to be plated are made the cathode in hot caustic potash solutions or solutions of potassium cyanide, common salt and so forth. The alkali given up at the cathode and also the hydrogen act as cleansers, and the grease is carried to the surface of the electrolyte, if it is animal fat in the form of soaps. But the fact of the grease floating on the surface of the electrolyte is a disadvantage, because when the cathode articles are withdrawn, they, on being raised out of the liquid, again become coated with grease from the matter floating upon the surface. In order to get over this difficulty it has been suggested, and even patented by Barth, of Frankfort (German Patent 195,975), that the upper layers of the liquid shall continually be allowed to flow away. The grease is then removed and the electrolyte is again returned to the bath.

Carbon anodes, it is well known, are very subject to corrosion, particularly when employed in baths containing cyanides, chlorides, or acids. In gold baths which usually contain cyanide it is therefore customary to employ anodes of platinum. Messrs. Siemens & Co., of Charlottenburg (German Patent 179,211), suggest the employment of silicon carbide (carborundum) as electrodes. This material is not only a very good conductor, but is a splendid electrode material, because it is practically unacted upon when used as anode. For example, an electrode of ferro-silicon was used in a solution of strong hydrochloric acid with a current density of 7–8 amperes per square decimeter, in 24 hours it lost 34 per cent. in weight. Under similar conditions a graphite electrode lost 17 per cent. in weight in 50 hours, but in 100 hours a silicon carbide electrode showed no measurable loss. On the other hand, ferrosilicon electrodes are fairly stable when they contain about 80 per cent. of silicon, but in this case the resistance is high. The *Chemische Fabrik Griesheim Elektron*, in their German Patent 193,367, protect the use of electrodes consisting of ferrous oxide, which, when in the molten condition, has added to it variable quantities of powdered, ferric, chromic, or manganic oxide. Carl Lindeman, of Magdeburg, German Patent 187,029, finds that carbon electrodes will withstand chemical anodic action better if they are saturated with platinum chloride and then ignited.

The rendering of non-conducting materials conducting upon the surface, so that metals may be deposited upon them, is a subject which has for many years received attention, several new patents having recently been taken out in this connection. Heller and Baumgartel (German Patent 189,410) paint the articles china, porcelain, &c., with petroleum and gold graphite. This latter is made by dissolving two grams of gold in aqua regia, evaporating to dryness, dissolving in 500 c.c. water, then adding 10 grams of potassium cyanide and one kilogram of finely powdered graphite. This mixture is then heated to 600° C., and then mixed with petroleum, is painted on the articles, which are then strongly heated. The surface is now evenly coated with a conducting film. Another method is to place the articles in a smoky flame; they are then said to be conducting, owing to the film of lamp-black formed on the surface.

There are various suggestions for treatment of aluminium in order to plate it with other metals. Most of the methods consist of scouring in alkaline or cyanide solutions or both, and do not appear to be any advance upon what has been done or suggested before.

A considerable amount of important work has been carried out upon the exfoliation of nickel when plated upon other metals, or, for that matter, upon itself. Nickel-platers are aware that when nickel is deposited from warm baths it is very much less apt to peel off than when cold baths are used. Römmler finds that electrolytic nickel always contains small quantities of hydrogen, but that the quantity is very much less at 75° than at 18°. Deposited metals which contain occluded hydrogen are invariably more brittle than when there is none present; this therefore explains why better deposits are obtained when the temperature is raised.

It was also shown that nickel exfoliates much less when the bath contains small quantities of free acid, the amount, however, must be very small. The higher the current density, however, the larger the amount of acid which may be added. Boric acid is often added to nickel baths, and all sorts of other things as well. We are of the opinion that nickel-platers would be much wiser to simplify their recipes and have as little extraneous matter as possible in their baths. Many recipes which one comes across contain substances which have directly opposed effects, and simply neutralise each other.

Rather complicated details for coating metals with tin are described, the articles being treated with a paste consisting of 5 per cent. zinc dust, 0·4 per cent. silver chloride, 12 per cent. salt, 0·9 per cent. of a tin salt, 20 per cent. tartaric acid, and 51·7 per cent. chalk. The older method in which tin or tinned articles are boiled with tartaric acid, and this solution, is afterwards employed, for tinning is simpler—the articles only requiring to be placed in the solution and connected with a piece of zinc.

In the English Patent 13,977, Mr. S. O. Cowper-Coles describes an electrolytic method for the manufacture of zinc dust. According to the patent, the zinc is electrolytically deposited in a spongy condition, and then in order to get rid of surface oxidation it is heated in a reducing atmosphere. The electrolyte is an alkaline one, consisting of a solution of caustic soda, and it is continually saturated with the zinc from anodes of this metal. On the other hand, the solution may be regenerated separately from the electrolytic cell, although even in this case an electric current is employed to dissolve the zinc. Probably the zinc powder obtained by this method can hardly be technically useful owing to the large amount of oxidation of the metal which would take place when drying it, and therefore it would require a considerable reduction before the oxide was got rid of.

Load Factor and Diversity Factor.—Mr. C. Le Maistre, Secretary of the British Electrotechnical Committee of the International Electrotechnical Commission, informs us that the definition of diversity factor, to which we took exception last week in the list of terms suggested by the Committee, was included in error, and that this should be, as we pointed out, the definition of "works load factor." The accepted definition of diversity factor is to be "The number obtained by dividing the sum of the maximum loads of the individual consumers supplied from any works during a given period of time by the maximum load delivered from the works during the same period."

Synchronising Public Clocks.—A Committee of the British Science Guild has made some recommendations with regard to synchronising public clocks, a subject to which considerable attention is being devoted at the present time. The committee suggest approaching the Postmaster-General, to ask that in the case of post offices, the time signals sent to the offices should actually automatically set at least one of the clocks in each public office to standard time; to form a deputation to the London County Council to ask them to have all public clocks under them, or in any way under their influence, synchronised in the same way; to take similar action with reference to the clocks under the control of the Corporation of London, the railway companies in London, and the Office of Works, which it is believed is responsible generally for the clocks in Government departments. The committee further recommend that the Local Government Board be asked to take the necessary steps to secure the passing of a bye-law calling upon persons exhibiting clocks publicly to have such clocks synchronised, or, failing this, for such clocks to be done away with. Similar action could be taken later on for provincial towns, and afterwards for smaller centres in Great Britain. It is understood that steps are being taken to carry out the recommendations of the committee.

The British Association.—*The Times* publishes some further particulars of the proceedings of the forthcoming meeting of the British Association in Dublin. Among the Papers of electrical interest down for reading under Section A (Mathematical and Physical Science) are the following:—"On the Measurement of Large Inductances containing Iron," by Sir Oliver Lodge and Mr. B. Davies; "Further Experiments on the Constitution of the Electric Spark," by Mr. T. Royds; "The Self-Inductance of Two Parallel Wires," by Dr. J. W. Nicholson. *The Times* also includes a Paper by Mr. A. P. Trotter on "The Position of the Mercury Ohm in British Legislation," but we are able to state that this Paper has been withdrawn. The programme of the Engineering Section is not dealt with.

ELECTRICAL SCIENCE

British and American

Selenium-Aluminium Bridges.—G. M. Minchin, in a Paper in the July *Proceedings* of the Royal Society, gives details of his experiments on a new type of sensitive selenium cell. The cell —which, by the way, the author calls a "seleno-aluminium bridge"—is made by placing a plain piece of aluminium at each side of a very thin sheet of mica, and then cutting perpendicularly through the three layers. The cut edge is taken and trued up, and on it is smeared a very thin layer of molten selenium. The aluminium pieces are thus electrically bridged by the selenium. The selenium is, of course, heated in the well-known way till it assumes the brownish-grey conducting form. When the length of the bridge is about a centimetre, and the thickness of the mica about one-hundredth of a millimetre, the resistance of the bridge under an E.M.F. of two volts may be about 40 or 50 megohms. The author states that it is advantageous to coat the selenium with a thin layer of solid paraffin. After numerous experiments, the author has been led to an empirical formula connecting the intensity of light falling on the selenium with the current through it before and after. If i_1 be the intensity of light of a definite wave-length which alters the current C_o into C_1 under an E.M.F. of about two volts, and i the intensity of the same light which alters C_o into C, then the experiments with red light and with blue light fit the formula:

$$\log \frac{C}{C_o} = \left(\frac{i}{i_1}\right)^n \log \frac{C_1}{C_o}.$$

For red light the index n is found to be 0·262, for blue light it is 0·36. There are described also experiments on the effect of the time of exposure of the selenium to the light, on the resistance of the selenium. Unfortunately the author does not anywhere in his Paper give the reader any notion of the absolute sensitiveness of the "seleno-aluminium bridge," and does not offer any comparisons of the sensitiveness of his form of selenium "cell," as compared with well-known types.

Battery for Very Constant Currents.—The ordinary form of Weston cell serves admirably as a laboratory standard of E.M.F., but cannot be used as a source of steady current, because of irregular cathode reactions. The cell is a cadmium amalgam, cadmium sulphate solution, mercury sulphate, mercury combination, and has a very small temperature coefficient of E.M.F. Some time ago G. A. Hulett found that the presence of a certain amount of sulphuric acid removed the irregular cathode reactions. He has therefore now designed and constructed cells of large electrode areas capable of giving comparatively big currents with a constancy quite unapproached by the best secondary batteries. Full details appear in the *Physical Review* for July. A cell for giving currents up to one-thousandth of an ampere is made by taking a wide-mouthed bottle with a bottom of about 100 sq. cm. area, and pouring in about five millimetres of mercury. Then the electrolyte is poured in to a depth of 4 or 5 cm. The electrolyte is made by adding 10 c.cm. of strong sulphuric acid to a litre of water, and dissolving in this an equal weight of cadmium sulphate crystals. The other metal pole of the cell is the cadmium amalgam, and this is carried in a shallow glass cup suspended by a glass tube from the paraffined cork in the neck of the bottle. Connections to the two electrodes are made in the usual way by platinum wires sealed through glass tubes. The mercurous sulphate layer with which the mercury electrode must be covered is formed *in situ* by passing current through the cell. A still larger cell has been made, having a mercury surface of 340 sq. cm., and four amalgam cups, each of 5 cm. diameter. This cell on open circuit had an E.M.F. of 1·02206 volts. Its internal resistance was less than an ohm. When closed by a 100-ohms resistance the P.D. across the terminals dropped to 1·01691 volts; when closed by 20 ohms the P.D. was 0·99196 volt, and after half an hour was 0·99190 volt. Four of these cells joined in parallel have been used for a considerable time to furnish a current of 0·15 ampere for bolometer work.

Continental

Thermoelectric Detectors.—In reply to Branly (see p. 223), C. Tissot points out, in the *Comptes rendus* for July 27th, that his tellurium detectors work without a battery, and are therefore not based upon a mere coherer effect. When they are connected with the antenna in parallel with a galvanometer, the galvanometer shows a deflection when waves impinge upon the system. The latter would hardly produce the unidirectional effect described if the detector simply operated by a variation of the closeness of the contact. Another characteristic difference is that the thermoelectric detectors respond, not in accordance with the amplitude of the variation of potential, but in accordance with the mean energy impinging upon the system. This may be proved by measuring the energy with a bolometer, an instrument by means of which detectors may be tested quantitatively. Good results are also obtained with other substances occupying extreme positions in the thermoelectric series, notably with fused sulphide of copper and its natural variety (chalcosine), as well as Becquerel's alloy, containing ten parts bismuth and one antimony. The thermoelectric detector may be described as a "total-effect" instrument. It has properties which fit it in a special way for the receipt of signals in selective telegraphy and in wireless telephony.

Selenium Cells.—A difficulty often encountered in the construction of photoelectric selenium cells is that the liquid selenium congeals into drops, and so fails to cover the surface evenly. In the *Physikalische Zeitschrift* for August 1st, W. S. Gripenberg shows how to avoid this by using selenium vapour instead of fusing selenium. Two grooves are cut into a glass plate, as closely as possible together, and parallel to each other. These grooves are rendered conducting by means of a deposit of platinum, and are connected with the terminals. The plate is then exposed to selenium vapour, preferably in an atmosphere of dry carbon dioxide. It is important that the plate should not be too hot, as otherwise the selenium fails to be deposited. A very slight silvering of the glass surface before depositing the selenium may possibly be useful. Such photoelectric cells are easily protected from damp and injury. The author has not suffered from any short-circuiting in this type. Since the grooves can be drawn very close together, the cells have a very small resistance, even if the layer of selenium is very thin.

Minimum Spark Potential.—The question as to whether there is a difference of potential below which no spark discharge can be obtained, whatever the limits within which the air pressure and size of gap are varied, is still far from being satisfactorily answered. J. E. Almy, in the *Physikalische Zeitschrift* for August 1st, brings forward some results which show, at all events, that no very small spark potential can be obtained by making the sparking distance excessively small. For electrodes he used fine platinum wires fused at the points, where they formed spheres only 0·008 cm. in diameter. The gap between them was measured by the interferometer. In another series of experiments steel needles, with a radius of curvature of 0·0007 cm. at the point, were used. He then obtained no discharge at 330 volts when the gap was as small as a quarter of the wave-length of sodium light, or fifteen millioneths of a cm. At 360 volts a discharge was obtained, but it was a kind of glow discharge, enveloping the point of the needle, but not proceeding from the point. There is no indication that a further reduction of the spark-gap would make discharge any easier. A P.D. of 300 volts (one electrostatic unit) is therefore required to pull an electron out of a piece of metal into the open air. For that is the interpretation of this form of "independent" discharge.

The French Association for the Advancement of Science.—The annual meeting of the French Association for the Advancement of Science is being held at Clermont Ferrand. The presidential address of Prof. Paul Appell, of the Sorbonne, dealt with education, and strongly condemned the present examination system. A feature of the second day's proceedings was Sir William Ramsay's lecture, entitled "A Fundamental Problem," in which the electron theory of the constitution of matter was discussed.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Aug. 6th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

16,503. **Leading-in Wires for Tungsten Lamps.** Deutsche Gasglühlicht A.G. (Auergesellschaft). Nickel leading-in wires give trouble owing to the nickel, when fused round the tungsten, forming a fusible alloy which runs down and leaves the end of the filament of diminished area. With copper fused round the filament end, the filament is apt to break through before the fused globule has solidified. The patent is for using a leading-in wire composed of two metals, such as nickel and copper, one of which readily forms alloys and the other does not. The two metals may be mechanically united, *e.g.*, copper-coated nickel, or may be in the form of an alloy. Four claims, four figures.

18,022. **Modified Connection of Field Regulating Switches.** British Thomson-Houston Co. (*General Electric Co., U.S.A.*). This device is intended more particularly for separately excited generator fields. A fixed field resistance is arranged permanently in series with the field coils, and an adjustable resistance is arranged, so that

Digitized by Google

it can be shunted either to the field or to the series resistance. At first it short-circuits the field, and its resistance is gradually increased until the coils are unshunted. The next stop of the switch handle places the adjustable resistance in shunt with the fixed resistance, and further movements gradually cut out resistance until the fixed resistance is short-circuited and the field is directly across the line. Three claims, one figure.

19,113. **Conduits for House Wiring.** H., A., and H. Pendlebury. The ends of the conduits are tapered instead of being screwed. The couplings and fittings are similarly tapered internally in an inverse direction. Both surfaces are machined. The ends of the pipes are also machined and tapered (or rounded off) internally. Three claims, five figures.

23,045. **Arc Lamp.** D. Timar and K. von Dreger. An arc lamp constituting an improvement on a former patent (No. 4,374 of 1902). The carbons are with their ends upwards, and are parallel when the arc is burning. Owing to the ends burning into a conical shape, it is necessary to bring the points together for striking the arc. To rotate the carbon holders is not sufficient, as the carbons then touch at some distance from the end, where the diameter has not been reduced by the burning. Under the present patent one of the holders not only rotates but moves away from the other holder when the lamp is switched on, in such a way that the points of the carbons are brought together to strike the arc. Three claims, seven figures.

24,251. **Neutralising Static Induction Effects on Telephone and Telegraph Wires on Single-Phase Railways.** British Thomson-Houston Co. (*General Electric Co., U.S.A.*). The catenary is charged to the same potential as the trolley wire, but its potential wave is displaced 180° in phase. The static effects of the trolley wire and its catenary on a neighbouring telepnone or telegraph wire thus neutralise one another. To charge the catenary in this way it is connected to earth through the secondary of a transformer, the primary of which is connected between the trolley wire and earth. It is mentioned in the body of the specification—although it is not claimed as an invention in the patent—that electromagnetic induction disturbances are largely avoided when sub-stations are connected to both ends of the trolley wire, as current then flows in both directions to the car, and the two inductive effects on the telephone wire tend to neutralise one another. Four claims, one figure.

26,404. **Speed-controlling Device for Hoisting Motors.** Siemens Bros. Dynamo Works (*Siemens-Schuckertwerke*). The ordinary check brake usually fitted on hoisting mechanism is so arranged that it is normally held out of action by the current until a certain speed is reached; at this speed the brake circuit is broken by a centrifugal governor, and the brake is thus temporarily applied. As the check brake is generally of too great power for this purpose, an alternative arrangement is proposed with the brake magnet divided into two parts, one of which is in circuit with the switch actuated by the centrifugal governor; or a stepwise action may be obtained by the further modification of having a switch in each of the parts of the brake magnet, the second switch being opened only at a higher speed than that at which the first switch is opened. Four claims, four figures.

1908 Patents

5,950. **Conduits for House Wiring.** Barton & Sons, Ltd., A. Barton and A. J. Harper. The socket end has a number of axial slits. The spigot end is placed within, and a ring which is tapered internally is then pulled over the slit spigot, drawing it tightly over the socket. One claim, four figures.

6,051. **Hardening Tantalum.** Siemens & Halske, A.G. It is known that silicon in proportions up to 1 per cent. is a hardening agent for tantalum. The present invention is to the effect that from 1 to 10 per cent. may be added without appreciably affecting the other good properties of the metal. This is especially the case with the ductility, which, however, diminishes when the proportion of added silicon is between 5 and 10 per cent., in order to harden the metal for the manufacture of parts of machines or for tools. A method of uniting the two metals is described by compressing a mixture of them and heating it by an electric arc between tantalum electrodes *in vacuo*. One claim, no figures.

9,289. **Multiple Maximum Demand Meter.** Hermann Aron. A double or multiple tariff meter, in which each counting mechanism operates its own maximum demand indicator, so that the maximum demand during different periods of the day is recorded separately. One claim, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

8,851, Mavor & Mavor & Coulson, Ltd. Polyphase induction motors.

14,451, Thompson (*Ges. für Drahtlose Telegraphie*). Production and detection of electric oscillations.

16,327, Lake (*Ingersoll Rand Co.*). Electro-pneumatic percussive tools.

16,485, Lenner. Regulating or controlling and measuring currents.

16,523, Brown, Boverie, & Cie, Akt.-Ges. Steam turbines with an impulse and reaction part.

16,577, Buchholz. Frames for supporting conductors in the open.

16,615, British Thomson-Houston Co., Wedmore, & Hamlyn. Protective devices for distribution systems.

16,630, Hudson & Bowring, Ltd., & Bowring. Life-guards.

16,719, Forbes. Arc lamps especially for signalling and searchlights.

16,735, Harrison. Electro-chemical deposition of metals.

16,862, Hake. Automatically operating gas or other valves or electric switches at predetermined times.

17,015, Marshall, Crookes & Robson. Portable electrically-driven machine for grinding, sawing, milling, and the like.

17,059, Grote & Ely. Arc lamps.

17,546, Preston & Theobald. Lamp holders.

18,924, Von Kando. Current-collecting devices for locomotives.

19,039, Wilkinson. Tramcar brakes.

19,784, Allgemeine Elektricitäts Ges. Switch mechanism for signalling systems.

20,361, Brooks & Alston. Tremblers of induction coils.

20,460, Haslop. Device for cleaning or trueing electric contacts.

20,662, Irgolitsch. Brake skate with sand strewing device.

23,710, Reist. Ventilating dynamo-electric machines.

23,801, Condon. Electrical water heaters.

25,426, Singer. Portable electrical vibratory massage apparatus.

25,863, Feather. Supporting trolley wires.

26,154, Siemens Bros. Dynamo Works & Birrer. Rotors of A.C. machines.

26,435, Bosch. Electrical ignition apparatus.

27,260, Goldschmidt. A.C. machine.

27,891, Barnett. Signalling to vehicles running on rails.

1908 Patents

2,152, Trivelli. Obtaining radio-active bodies from uranium or its compounds.

2,495, Bloxam (*Siemens Schuckertwerke-Ges.*). Electrically-propelled motor road vehicles.

2,871, Hutton. Appliances for use with telephone transmitters for preventing the overhearing of telephone conversations.

3,418, Wilkinson. Tramcar brakes.

3,583, Seibt. Radio-telephony.

3,860, Marks (*Electrical Manufacturing Co.*). Switches.

3,979, Fraser & Chalmers, Ltd., & Whitmore. Valves of mixed pressure turbines.

5,015, Harrison (*Electric Railway Improvement Co.*). Method of joining metallic bodies by means of an electric current chiefly designed for use in bonding rails.

5,948, Geb. Korting Akt.-Ges. Injectors.

7,586, Jones. Electrically-operated signals for railroads.

7,792, Sexton & Sexton. Sand distributing apparatus for tramcars.

8,017, Branco & Gumpert. Process for the manufacture of a material from peat for electric and heat insulation, sound-deadening, and other purposes.

8,288, Felten & Guilleaume Lahmeyerwerke Akt.-Ges. Differential relays.

8,414, Allgemeine Elektricitäts-Ges. Commutator motors.

9,479, Schäffer. Supporting hooks for lamp filaments.

9,501, Baggett. Arc lamps.

9,577, Allgemeine Elektricitäts-Ges. Dynamo-electric machines.

9,637, Siemens Schuckertwerke - Ges. Dynamo-electric machines with commutation poles.

11,432, Firm of Unterburg & Helmle. Actuating device for magneto-electric ignition apparatus.

13,837, Buchholz. Means for mounting on poles slotted hollow arms for supporting electric conductors in the open.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

13,854, Snook. X-ray system.

14,596, Lohay. Control of mechanism from a distance.

15,118, Siemens & Halske Akt.-Ges. Signalling installations particularly for fire alarms.

15,370, Beschelberger. Automatic switch device for the inductor of telephone apparatus.

15,491, Soc. pour l'Utilisation de l'Air et de ses dérivés. Safety device for high-pressure apparatus.

Expiring Patents

No patents of electrical interest expire during the current week.

LOCAL NOTES

ABERDEEN: *Tramway Accounts.*—The accounts of the Corporation Tramways Department, which we gave in our issue for July 30th, were passed at a meeting of the Corporation last week.

Municipal Tramways Conference.—The Convener of the Tramways Committee and the General Manager are to attend the annual conference of the Municipal Tramways Association, which will be held in Nottingham in September.

Supply for Wireless Telegraphy.—The Electricity Committee report that they have been in correspondence with the Admiralty in regard to the supply of electricity to a proposed wireless telegraphy station to be erected at Stoneywood. The committee recommended that a supply be given at a flat rate of 3½ per unit, the Admiralty to guarantee a payment of £350 per annum for five years, the Corporation to lay the feeder cables from Ferryhill to Stoneywood, and the Admiralty to pay the sum of £1,000 towards the cost.

ARGENTINE: *Telephone Progress.*—At the end of 1907 the United River Plate Telephone Co. had 15,499 subscribers and the Co-operative Co. 5,601.

AUSTRALIA: *Victoria Tramways.*—The *Australian Mining Standard* says that although the revenue of the St. Kilda-Brighton (V.) electric tramway for the year which closed on June 30th was actually £911 higher than that for the previous year there is again a deficiency on the year's operations of about £5,450. This, however, is not much more than half of last year's deficiency, which amounted to £9,782. But it must be borne in mind that the fire which destroyed the power-house, the car-sheds, and rolling stock in March, 1907, necessitated heavy expenditure, both last year and this; the outlay on this account during the previous financial year was £9,941, and during the year just closed £5,000 more has been spent on replacements. Then heavy interest charges have to be taken into account, and these amounted to about £2,000 for the past year. The balance-sheet, therefore, stands as follows:—Estimated expenditure, £15,800; estimated revenue, £10,350; estimated loss, £5,450. If it were not for the £5,000 for replacements, and the £2,000 interest, the loss would have been only £450. The actual revenue for eleven months was £9,700, and that for June is estimated at £650, making up a total of £10,350; whilst actual working expenses were £10,800. The total cost of making good the damage caused by the fire was estimated at £15,200, and of this £12,941 has been expended up to the end of June, leaving £2,259 still to be provided.

Victoria.—The Bendigo City Surveyor has drawn up a scheme for utilising one of the falls in the Coliban water race, between Sedgwick and the Crusoe Reservoir, for generating electricity for public lighting in the city and suburbs. The estimate for supplying and fixing a generating plant, including a transmission line to the city boundary, is estimated at £10,260. The report has been referred to the committee of the Council for consideration.

BANBRIDGE: *Electric Lighting.*—Messrs. T. L. Miller, Wilson, and Pegg have placed a scheme of electric lighting before the Council, under which they show considerable savings compared with the present system of public lighting by means of gas. A special meeting is to be held to consider the matter.

BARRY: *Electric Lighting.*—The Barry Chamber of Trade has disapproved the proposed electric lighting scheme of the Council.

BELFAST: *Cavehill and Whitewell Tramways.*—At the last meeting of the Corporation a resolution was moved "That it be an instruction to the Tramways and Electricity Committee to postpone further negotiations with the Cavehill and Whitewell Tramway Co. for the purchase of that company's undertaking for twelve months." The mover of the resolution stated that his reason for it was the unsatisfactory position of the Corporation tramways undertaking. After some discussion the resolution was withdrawn, the Mayor stating that so far as he knew, the Committee had no intention of buying the company's undertaking.

Tramway Fares.—At the weekly meeting of the Tramway and Electrical Committee on Monday the fares question was again discussed for some time, and the Town Clerk, Sir Samuel Black, submitted counsel's opinion, which was that the fares recently put in force are in accordance with the law.

BERKHAMSTED: *Provisional Order.*—The Chesham Electric Light & Power Co., Ltd., have notified the Council of their intention to apply for an electric lighting Provisional Order for the district.

BLACKROCK: *Electric Supply.*—At the August monthly meeting of the Council a report was presented with regard to the Central Ireland Electric Power Bill, which has been passed by Parliament, containing all the clauses which were specially provided to safeguard the interests of Blackrock. A provisional agreement has been entered into between the Council and the promoters of the Bill for a supply at 1¼d. per unit up to a certain point, and 1½d. per unit after that.

BOURNEMOUTH.—*Electric Cliff Lift.*—An electric lift on the West Cliff was opened on August Bank Holiday. It will be remembered that a similar lift on the East Cliff was opened a short while ago.

BRIGHTON: *Power Supply.*—A provisional agreement between the Electricity Committee and the London, Brighton & South Coast Railway Co., for a supply of electric power to the company's Brighton works (full particulars of which we gave in our last issue), has been confirmed by the Corporation. In moving the adoption of the agreement at the last meeting of the Corporation, Alderman Carden, the Chairman of the Electricity Committee, suggested that some portion of the £750 standing charge to be paid by the railway company should be placed towards the repayment of the capital charge, and thus shorten the time for the repayment of the loan. The agreement was eventually signed and sealed.

BURNLEY: *Death of Tramway Committee Chairman.*—The death took place on August 5th of Alderman Metcalfe, who was Chairman of the Tramways Committee, to which position he was appointed in 1906.

CARDIFF: *Condition of Tramway Track.*—Notice has been given of a resolution at a City Council meeting, asking for the appointment of an expert to investigate the "causes of the disgraceful and dangerous state of the tramway track and to recommend the best way of placing and keeping the said track in a satisfactory and safe condition."

Tramwaymen's Wages.—The Tramways Committee has again been considering the conditions under which the tramway employees are working. After a long discussion it was decided to pay the men time and a quarter overtime after nine and a half hours per day, and not to give increased wages.

CLEVEDON: *Electric Lighting.*—A proposal that the Council should apply to the Board of Trade for an electric lighting Provisional Order was rejected at the last meeting.

COLCHESTER: *The Electricity Works.*—The local papers state that a report of the Council in committee concerning the position of the electricity department has been presented, but that it is so mysteriously worded as to convey no information. It may be recalled that some time ago complaints were made as to alleged nuisance from the electricity works, and as extensions were contemplated, Messrs. Mordey and Dawbarn were called in as consulting engineers to advise on the whole position, and especially as to the erection of a new generating station on another site. A consultative sub-committee has been formed, but no definite proposals from it have been forthcoming. It was stated in the Council last week that the works are so fully loaded that if an accident happened to one of the machines during the "peak," either the tramways would have to be suspended or part of the lighting shut down. It appears that Messrs. Mordey and Dawbarn have advised the Corporation that there is a cheaper way out of the difficulty than building a new station, but no definite information was given at the last meeting, when the matter was discussed.

DAMASCUS: *Electricity Supply.*—A British Consular report states a line of 3⅓ miles of electric tramway was ready and open for traffic on February 7th, while the lighting part of the project was not finished till July. Very few private houses are as yet lighted by electricity, but it is expected that most of the well-to-do people will soon use it. The hotels, coffee houses, and theatres are now nearly all lighted with electricity, besides the great mosque and the principal streets. The railway stations are not so lighted.

DARLINGTON: *Tramway Revenue.*—For the first seven months of 1908 there has been a decline of 7 per cent. in the tramway receipts, a result which is attributed to trade depression.

Electricity Charges.—The charge for private lighting is to be reduced to 3½d. per unit, owing to the competition from gas. This is the lowest price in the North of England with the exception of Newcastle, which is the same.

DARTFORD.—*Rural Provisional Order.*—The Board of Trade have decided to defer for six months the question of revoking the Strood and Dartford (Rural District) Electric Light Order, 1903.

DENNY: *Electricity Supply.*—The Town Council has unanimously decided to proceed with a scheme of electricity supply. An agreement has been come to with the Electric Power Co

DONAGHADEE: *Electric Lighting.*—A firm of electrical engineers have placed before the Council comparative figures showing the saving which would be effected by the establishment of an electricity works as against a gas works. Further particulars have been asked for.

DUNDEE: *Tramway Accounts.*—The annual report of the Tramways Committee shows that the revenue for the past year amounted to £60,572, and the expenditure to £39,879. The balance of £20,692 has been applied to capital charges, depreciation, renewals, &c. The passengers carried numbered 16,176,134, an increase of 621,229, and the mileage run was 1,281,552, an increase of 118,760.

Third-Party Risk.—At the last meeting of the Town Council objection was taken to the proposal to set aside £1,000 out of revenue as insurance against third-party risks. It was suggested that this sum was inadequate, and that £1,500 should be so allocated. The committee's recommendation to set aside

Digitized by Google

£1,000, however, was passed, it being pointed out that they had never yet paid more than £525 in one year.

FELIXSTOWE: *Nuisance from Electricity Works.*—Complaints have been made of alleged nuisance from residents near the electricity works, and the letters in question have been referred to the engineer.

FINLAND: *Telephones.*—In a British Consular report it is pointed out that in Helsingfors the number of telephone subscribers already exceeds 7,000, the population being 160,000. The telephones are not a Government monopoly and their cost never exceeds £3 3s. per annum.

Electric Railways.—The electric railway from Hyvinge station to Naas estate, a distance of 9·3 miles, built at a cost of about £16,000, has been in operation since January, 1908, and was recently officially inaugurated. This line may probably be extended to Hangö and Forssa.

GILLINGHAM: *Local Government Board Inquiry.*—Mr. H. R. Hooper, of the Local Government Board, has commenced an inquiry into the general position of the Council's electricity undertaking, mainly with the view of ascertaining in what manner the present loss may be mitigated or obviated. Mr. Hooper some time ago carried out a similar inquiry at Buxton, and as his recommendations in that instance proved beneficial, he has recommended that Mr. A. D. Chalmers, the Gillingham Council's electrical engineer, should pay a visit there, as the circumstances of the two places are peculiarly identical. When this recommendation was laid before the Council at its last meeting, opposition was taken to the Council having to pay the expenses of the trip, it being suggested that the journey was being made simply to educate the engineer up in his own work. It was ultimately decided that the engineer should visit Buxton.

GLASGOW: *Electricity Accounts.*—The gross revenue of the electricity undertaking for the year to May 31st was £255,462, and the working expenditure £115,318; from the balance there has to be deducted £54,715 interest on loans, and £52,308 sinking fund charges. The balance for the year is therefore £51,061, compared with £44,824 last year. From this balance there has to be written off £50,151 for depreciation, and the balance of £910 has been transferred to reserve fund account, which now stands at £22,122. The total capital expenditure to May 31st, less depreciation, stood at £1,685,085, of which £147,798 were expended during the year. The number of consumers is now 16,926, an increase of 1,429 for the year, and the quantity of electricity sold to private consumers was 31,087,522 units, an increase of 26 per cent. over the previous year. There are now 3,853 motors, with a total horse-power of 25,748, connected to the mains, against 3,302 motors in the previous year, with a total horse-power of 19,805. The public lighting consists of 857 arc lamps, and the maximum demand upon the station was 22,186 kw., compared with 19,645 kw. during the previous year. In view of the favourable position of the undertaking (the income for the year having increased by £28,557, whilst the working expenditure has only increased £9,081), the Committee recommend considerable concessions in the charges for electrical energy. For private lighting purposes the charge will be 5d. per unit instead of 3½d. per unit, whilst the charge to the Watching and Lighting Committee for public street lamps has been reduced by £2 per lamp per annum.

GRANTHAM: *Audit of Electric Lighting Companies' Accounts.*—The Council, which has the option of purchasing the undertaking in the town of the Urban Electric Supply Co. at the end of seven years, and afterwards at the end of every seventh year, has decided to support the Bermondsey Town Council in its protest against the action of the Board of Trade in doing away with the official audit of electric lighting companies' accounts, and to accept the audit of the companies' own auditors.

GRIMSBY: *New Generating Set.*—A new 500-kw. generating set has been erected at the power station, and will shortly be ready for testing.

GREENOCK: *Electricity Surplus.*—After meeting interest and sinking fund charges, there is a surplus of £700 upon the working of the electricity undertaking for the past year.

HALIFAX: *Record Tramway Receipts.*—During the three days of the Yorkshire Show, the receipts upon the Corporation tramway system amounted to £1,375, being £711 more than those for the three corresponding days of last year.

HASLINGDEN: *Through Tramway Communication.*—Negotiations between the Haslingden and Rawtenstall Corporations as to through running of electric trams have, for the present, been broken off.

Tramway Supply.—Owing to the fact that the Lancashire Power Co., with whom the Council had arranged to take a supply, does not now intend to carry their cables into the district for the present, a difficulty has arisen with regard to working the tramways. The reconstruction of the lines from horse traction is nearly completed, but under their Act of Parliament the Council is prevented from erecting a generating station. The Local Government Board has been communicated with.

HASTINGS: *Sunday Trams.*—Notwithstanding the Corporation a few weeks ago passed a resolution that Sunday trams should only be allowed on the understanding that the profits from them should not be taken into account in any purchase negotiations, the Hastings Tramways Co. continues to run its cars on Sundays. It is said that the opinion has been expressed by two eminent King's counsel that the resolution of the Council is illegal.

HULL: *Municipal Tramways Conference.*—The Chairman of the Tramways Committee, Deputy Chairman, the Tramways Manager, and the Electrical Engineer have been authorised to attend the Tramways Conference in Nottingham in September.

ITALY: *Genoa: Tramway Tunnel.*—A tunnel more than a mile in length, said to be the longest in existence for use by a tramway, has just been opened by the Genoa Street Railway Co. It connects Genoa with Rivarolo. The work of constructing the tunnel was commenced on June 1st, 1905.

LEAMINGTON: *Accident to Electrical Omnibus.*—An electrical omnibus, belonging to the Warwick and Leamington Electrical Co., was descending a steep incline near Leamington on Monday last week, when the brakes failed to act, and the vehicle got out of control. The driver managed to steer the vehicle safely until a waggon lower down the hill blocked the road, and in endeavouring to avoid this the omnibus dashed into a cottage on the roadside. Ten of the passengers were injured, and had to be conveyed to the Warnesford Hospital, Leamington.

LEITH: *New Generating Set.*—A new steam dynamo was put into operation at the electricity works last week, when the Convener of the Electricity Committee took the opportunity of reviewing the progress of the undertaking since its inception. He stated that in 1898 the plant installed consisted of five small steam dynamos of an aggregate capacity of 720 h.p.; in 1900 a further 550 h.p. was added; in 1901 another of 500 h.p. capacity; two further sets of 600 h.p. each were added in 1903, and one of 1,000 h.p. in 1905, whilst with the 1,000 h.p. set just put into operation, the total capacity of the plant in the station was now 4,770 h.p. It is interesting to note that this latter set has cost only about £200 more than the 500 h.p. set of 1901 in capital cost.

LIVERPOOL: *Tramway Loans.*—Tenders to the amount of £1,785,000 have been received in response to the Corporation's invitation for tenders for £500,000, the average rate of the tenders being £2 6s. per cent. discount. The rate at which the last bills were issued was £3 4s. 9½d. per cent.

LONDON: *Westminster: Smoke Nuisance.*—In his annual report the Medical Officer of Health, Dr. F. J. Allan, again draws attention to the desirability of steps being taken to have the qualification "black" omitted from the section of the Public Health Act which deals with smoke nuisance. Dr. Allan asserts that it is owing to the smoke nuisance in Westminster that in 1907 there were in Westminster 200 hours of sunshine less than in the suburbs of London.

St. Pancras: Tramway Track.—A deputation has waited upon the Highways Committee of the London County Council to urge the retention of the wood paving of the tramway tracks along Hampstead Road and High Street. In reply to the request, Mr. Whitaker Thompson, the Chairman of the Highways Committee, pointed out that as the Borough Council had insisted upon the conduit system, which necessitated an additional metal rail and therefore further increased the cost of maintenance, the Borough Council should meet the County Council by agreeing to pay the increased cost of maintaining the wood paving. The committee could not see their way to treat St. Pancras differently from the rest of London. A resolution was passed at the last meeting of the Borough Council authorising the Town Clerk and the Borough Engineer to continue during the vacation negotiations with the London County Council with a view to arriving at a settlement of the dispute.

Stepney: Meter Rents.—The Electricity Committee reports that they find the Council is in an unduly disadvantageous position with regard to those consumers whose consumption is regulated by time switches. A rental of 6d. per month is charged for these time switches, and the Borough Electrical Engineer has demonstrated to the Electricity Committee that the consumers effect a very considerable saving in their accounts by their use. As, however, the cost of the installation and maintenance of these instruments is more than that of the ordinary meter, the committee are of the opinion that the present time switch meter rental should be increased to 2s. per month in order to cover the out-of-pocket expenses of the Council. This report has been adopted.

MAIDSTONE: *Electricity Finances.*—The accounts for the year to March 31st show a surplus, after meeting capital charges, of £1,278. The units sold show an increase of 200,000 over last year, three-fifths of which is due to the Loose and Tovil tramways, but, in spite of the introduction of metal-filament lamps, the units sold to private consumers for lighting showed an increase of 5·5 per cent. In several towns, although the number of consumers had increased, the units sold for lighting purposes, the engineer points out, had decreased. The units sold for power purposes did not show such a large increase as last year, owing chiefly to several large consumers not being so busy. The revenue has increased by £1,400, while the costs have only increased by £411, and the gross profit upon the average capital employed is the satisfactory figure of 8·1 per cent. The total costs per unit sold is 1·05 pence. In the final paragraphs of his report Mr. Hoadley says that what is very badly required, however, is a reduction in the selling price of metal-filament lamps. Electrical cooking and heating apparatus was becoming

Digitized by Google

much cheaper, and more reliable, and the price was bound to come down still further as the apparatus became more general. In the field of power supply, especially where small units of power were required over an area, electric motors stood practically alone, and to-day it was in very few cases that prejudice or want of confidence in their ability to do the work had to be overcome.

MANCHESTER: *Mutual Telephone Co.*—At the meeting of the Corporation on Thursday, Dr. Skinner proposed the appointment of a special committee to consider and report upon the position of the Corporation towards the Mutual Telephone Co., Ltd., and as to whether or not any payment should be made by the Corporation to reimburse the expenditure incurred by the company in endeavouring to promote a telephone system for Manchester. Dr. Skinner argued that the Council was in honour bound to make some recompense to the company in consequence of their having incurred expenditure as a result of a resolution which was subsequently rescinded. The motion was lost.

Trolley Omnibuses.—At the last meeting of the Corporation, a recommendation by the Tramways Committee authorising the Chairman, the Deputy-Chairman, the Chairman of the Permanent Way Sub-committee, and the General Manager of the tramway, to visit Germany to inspect some trolley omnibuses was carried. One councillor, however, objected to the constitution of the deputation on the ground that none of the members possessed any scientific knowledge of the subject, and suggested the appointment of some other persons who understood the business, and who would be able to bring back an intelligent report. It was pointed out that if the trolley system of omnibuses was found practicable it would be very useful in certain districts for which the Tramways Committee is bound to provide a service. For instance, Urmston was approached from Stretford by narrow winding lanes, and the adoption of the system there would save a large expense in street widenings.

Compensation for Tramways Accidents.—At the last meeting of the Corporation it was stated that the amount of compensation paid for tramway accidents during the past year was £15,000, against £9,000 for the previous twelve months. The Chairman of the Tramways Committee said he could only account for the increase by the fact that people were beginning to realise more the claims they could make for compensation for any slight accident. It would soon become a question for consideration whether the Tramways Committee should endeavour to make the best terms by insurance or go on as hitherto.

NEWCASTLE-ON-TYNE: *Tramwaymen's Grievances.*—The Newcastle Tramway Workers' Union has petitioned the Corporation Tramways Committee for protection of the drivers against cold and wet. The revision of some day duties which in some cases were spread over 13 hours with more than nine hours' actual work, was also asked for, and the recognition of long service in the case of enginemen and firemen at the power station, brakesmen and handy men at the depôts, none of whom were granted the 1s. a week conceded to workers last year in recognition of three years' service. The committee has replied to the effect that the covering in of the motormen's driving platform, &c., could not be entertained, and in regard to the revision of day duties, the committee considered that they had done all in their power and could do nothing more. As to the recognition question, the committee considered that nothing further could be done in the matter. On the holidays question the committee, in their reply, stated that they must have the services of the men on Saturday. The Union has decided to ask the Tramways Committee to receive a deputation on the questions in dispute.

NEWPORT: *Power Supply by Non-Statutory Companies.*—The Corporation has, in response to a communication from the Incorporated Municipal Electrical Association, agreed to support the views expressed at the Nottingham Convention with regard to opposing the granting of wayleaves along their tracks by railway companies to non-statutory electric power supply companies for the purpose of laying mains. The question was raised by the Scotch representatives at Nottingham *apropos* of a suggested scheme of this nature in the West of Scotland.

Third-Party-Risks.—The Electricity Committee have decided to accept the offer of the British General Insurance Co. to insure the tramways against claims above £1,000 and up to £10,000, with a total of £20,000 in one year, at an annual premium of £70; and they have also decided to reduce the proportion to be paid to the Corporation's own fund to £400 per annum, instead of about £650, as at present.

NORWAY: *New Electric Railway.*—H.M. Embassy at Christiania reports the opening of the first electric railway in Norway, from Thamshaven to Svorkmo, a distance of about 20 miles. The power station is some six miles from Thamshavn and the power is generated by a waterfall 58 metres high, developing 3,000 horse-power, and driving five turbines. In addition to passengers, the railway will carry copper ore from the Meldal mines, the owners of which are also the proprietors of the railway.

NUNEATON: *"Rateable Value" Basis of Charging.*—A new scale of charging for electric supply has been put into force, viz., on the basis of 15 per cent. of the rateable value of the property supplied, plus 1½d. per unit. Consumers preferring the old flat rate of 5d. per unit will be allowed to continue on this.

OLDHAM: *Smoke Nuisance.*—At a meeting of the Town Council last week, Councillor Cheetham asked why mill companies were continually prosecuted for the emission of black smoke from their factory chimneys, whilst the electricity station belched forth black smoke daily, and was allowed to continue without prosecution. He contended that the power station chimney was a bigger nuisance than any other in the town, and whilst the Corporation were the biggest owners in this respect, he would refuse to support any further prosecutions for black smoke nuisance. The Chairman of the Electricity Committee replied that the smoke inspector had taken numerous observations of the power station chimney and found no fault with it.

OXFORD: *Electrobuses.*—It is stated that the Electric Vehicles Development Co. has made application to the Corporation for permission to run a number of electric omnibuses.

PAISLEY: *Electricity Finances.*—The Borough Treasurer, in submitting his annual statement regarding the financial position of the various departments of the Burgh, states that he found the electricity department in somewhat straitened circumstances, mainly owing to the short term allowed for repayment of loans and the large ratio of capital to earning power. This year the deficit was £853, and it was clear that they had been selling current at less than cost price. Admittedly private lighting was a remunerative item, and therefore the loss must arise from the supply for power and traction purposes. The greatest gainers evidently were the Paisley and District Tramways Co., who took 1,581,870 units out of a total of 2,035,612 for power and traction. A very adverse factor during the year had been the excessive price of fuel, which cost £1,163 more than in the previous year.

PERTH: *Extension of Electricity Boundary.*—An inquiry under the Private Legislation Procedure (Scotland) Act, 1889, was held last week, into an application by the Corporation to extend the boundaries of the city and the limits for the supply of electricity, &c. The application also included authority to construct certain new tramways. For the latter purposes borrowing powers amounting to £11,500 were asked. These portions of the order were passed by the Commissioners.

PERU: *Electrical Appliances.*—According to a British Consular report the market for electrical appliances in Peru is very limited. In Lima there are electric tramways, urban and suburban, and an electric light plant. Electric power is very little used for industrial purposes; 100 horse-power per hour costs £1 1s. 6d. Light for private houses is expensive, 16 candle-power lamps cost about 8d. per kilowatt hour. Moreover, the Santa Rosa Electrical Company have a clause in their concession which stipulates that no consumer can use any appliances which they (the Company) do not provide. The regulation of the current supplied by this Company is very unreliable, so that lamps are continually being burnt out and the light is very unsatisfactory. It is estimated that there are 25,000 lamps actually in daily use in the town of Lima. The Company also supply light to Callao, but many, if not the majority of people at this port, prefer to use gas which, bad as it is, is found to give more satisfaction.

PLYMOUTH: *Electricity Accounts.*—The Electricity accounts, which were abstracted in our issue for July 23rd, were approved at the meeting of the Council on Monday. Mr. Anthony, in moving the adoption of the minutes of the Electricity and Street Lighting Committee, said the receipts for private lighting had fallen off, no doubt due to the fine weather during June last, when there were only five wet days; in June, 1907, there were only the same number of fine ones. The annual report of the electrical engineer was entirely satisfactory, and reflected great credit upon Mr. Okell and the electricity staff. In spite of the increased price of coal, the price of the electric light had been kept the same as before. The reserve fund had now gone up to over £9,000, and it was thought the time had now arrived when the reserve fund should be invested, and the interest used as a contribution towards the sinking fund charges. He thought some of the committee could assist the Electric Light Committee in this matter, and have the Corn Exchange and the Meat Market and other public buildings lit with the electric light. A petition had been received from residents of property in Treville Street suggesting that the electric light should be used instead of gas. It indicated that, as far as the public were concerned, they preferred electricity to gas. Unfortunately the Council had cut down the estimates, and the committee were unable to accede to the request.

PORTSMOUTH: *Electricity Surplus.*—The sum of £2,000 has been handed over to the relief of rates from the profits of the electricity undertaking for the past year.

ROCHFORD (Essex): *Tramways and Lighting.*—The Rural District Council has decided not to offer any opposition to a proposed scheme of tramways and electric lighting embracing Leigh and Hadleigh.

SALFORD: *Tramway Accounts.*—The annual report of the General Manager for the year ended March 31st, 1908, states that the total length of tramways worked by the Corporation at that date was as follows:—Salford, 36¾ miles (owned by Corporation); Manchester, 9½ miles (running powers by agreement);

Digitized by Google

Eccles, 8 miles, Swinton and Pendlebury, 6¾ miles, Prestwich, 7 miles, Whitefield, 4½ miles (all the above are leased to the Corporation); Trafford Park, 2½ miles (worked jointly with the Manchester Corporation). The total mileage owned or worked was therefore 75 miles. The total quantity of electrical energy used during the year for haulage, lighting of cars, &c., was as follows:—Supplied by Salford, 7,195,501 units; Manchester, 1,185,029 units; Eccles, 322,054 units. After making allowance for the quantity recharged to the Corporations of Manchester and Bury, the total quantity used by Salford cars was 8,575,959 units. The car mileage run in connection with the above amounted to 5,416,948 miles, giving an average consumption of 1·58 units per car mile. There were 176 cars in stock on March 31st, but consequent upon the increasing demands tenders have been accepted for the supply of 24 cars of the single truck, double-deck type, with outer covers. The traffic returns for the year show an increase in the gross receipts of £6,947, but the average receipts per car mile are slightly less than the figure for the previous year, due in a large measure to the large amount of wet weather prevailing in the summer months. From the Borough Treasurer's statement of the income, expenditure, and financial position of the tramways undertaking, at March 31st, 1908, it is seen that the year's working resulted in a gross profit of £92,276, to which must be added interest on investments, &c., making a total available balance of £96,761; payments to local authorities for running powers, &c., absorbed £25,893; interest and sinking fund charges, £41,970; repairs, &c., of property, Church Street, £92; contribution in relief of rates, £18,000; depreciation and renewals fund, £10,806. The amount standing to the credit of the depreciation and renewals fund at March 31st, 1908, was £58,307. The following further particulars relating to the undertaking are given in the report:—Total borrowing powers, £1,192,599; borrowing powers exercised, £684,858; unexhausted borrowing powers, £507,741; gross capital expenditure, £689,384; traffic revenue, £238,856; total revenue (including interest on investments, &c.), £244,048; working expenses, £147,286; passengers carried, 45,771,611; percentage of working expenses to receipts, 60 per cent.; average revenue per car mile, 10·67d.; working expenses per car mile, excluding power cost, 4·47d.; average working expenses per car mile, including total power cost, 6·44d.; average fare per passenger, 1·25d.; total amount of sinking fund in hand and unapplied, £98,764 3s. 11d.; amount of sinking fund applied in reduction of debt, £46,708 2s. 9d.

Proposed New Generating Station.—Negotiations are proceeding for the acquisition by the electricity department of the site of the Wilburn Street depôt for the erection of a new generating station.

SHEFFIELD: *Tramway Accounts.*—For the year ended March 25th last the revenue from the Corporation tramway system was £292,395, whilst the total working expenses were £177,949. After meeting capital charges there is an actual credit balance of £47,471. The number of passengers carried was 77,568,686.

SOUTH SHIELDS: *Electric Railway.*—The powers of the North & South Shields Electric Railway Co. for the compulsory acquisition of land belonging to the Corporation have expired.

Electricity Accounts.—The accounts of the electric lighting undertaking, which were given in our issue for July 16th, have been adopted. The gross profits for the year amounted to £12,070, equal to 6·8 per cent. interest on the capital outlay.

SOUTHGATE: *Electric Supply.*—Mr. W. C. C. Hawtayne has been retained to advise the Council with regard to the agreement with the North Metropolitan Electric Power Supply Co., at an inclusive fee of £31 10s.

STEYNING: *Electricity Charges.*—The Brighton Corporation have notified the Council of increase in the electric supply tariffs to 4½d. per unit for lighting, without restriction; 2d. per unit for power and heating, and 2s. 6d. per quarter rental for meters. Complaint is made that the flat rate for lighting is 4d. in Brighton, and the Council think Steyning should be granted the same terms. The respective Town Clerks are to confer.

STOCKTON: *Overhead Wires.*—The Cleveland and Durham Electric Power Co. has communicated with the Rural District Council with regard to their overhead wires in Haverton Hill district, and pointing out the arrangements made to render them as safe as possible. The company point out that the length of span is short, the voltage much less than that ordinarily allowed in tramway cables, whilst the cables are stronger, and the risk of breakage is reduced to a minimum. In addition, the protective device would come into operation immediately the wire snapped or touched anything. The question has been deferred for a fortnight, and in the meantime information will be obtained as to the conditions imposed upon the company in other districts.

SUNBURY: *Electric Lighting.*—Notice has been received by the Council from the Electric Light & Traction Co. of their intention to apply for an electric lighting Provisional Order for this district.

SWINTON: *Re-opening of Tramways.*—A portion of the old Dolter surface-contact system has now been converted to the overhead trolley system, and opened for traffic. The section now working is between Rotherham and Swinton, and the remaining section, about two miles, between Swinton and Mexborough, is being pushed on with. Local satisfaction is expressed at the cars now keeping schedule time.

TORQUAY: *Electric Supply.*—An application has been received from the Dolter Electric Traction Co. for an increase in the maximum supply of current for tramway purposes, and upon this a report has been made by Messrs. Kincaid, Waller, Manville & Dawson, the consulting engineers to the Corporation. In this report the suggestion is made that an oil-driven plant should be installed in the present power station at an estimated cost of £6,820, but the committee are unable to recommend the acceptance of this suggestion. They have, however, considered in detail a report by the electrical engineer, which pointed out that whatever additional plant was installed in the present station, it would only meet the difficulty temporarily, and that in his opinion the ultimate removal of the works would have to take place in a year or two. He was of the opinion that before any decision was arrived at in regard to the addition of plant on the present site, the tramway company should be asked to give a guarantee not to apply for a further increase in their maximum demand for a period of at least two years. In order to meet the present demands of the company, Mr. Storey, the electrical engineer to the Council, suggests that the present motor generator should be divided up and a new high-speed steam engine and sole-plate fitted to the direct-current portion, thus forming a completely new unit of 250-kw. capacity. He also proposes to put in a new surface condensing plant with electrically-driven air and circulating pumps. With the cost of removing foundations and other alterations, the estimated cost of this scheme is put at £2,954. This recommendation has been confirmed by the Council.

WIGAN: *Electricity Finances.*—Mr. H. R. Hooper resumed last week on behalf of the Local Government Board, the inquiry into an application for sanction to additional capital expenditure upon the Corporation electricity undertaking, which was commenced as far back as in November, 1906. The first inquiry, which was divided into two parts, viz., the expenditure of unauthorised capital, and proposed extensions at the generating station, was adjourned, *sine die*, the inspector asking that more elaborate details be prepared. Since then, it has been thought advisable to hold two inquiries, one dealing with over expenditure, the other with the proposed extensions. To this suggestion the Board agreed, and the inquiry was resumed on July 29th last, dealing only with over expenditure The inspector was quite satisfied with the particulars produced, and at the conclusion of the inquiry, complimented the officials on the way the information had been prepared. The position now is that excess expenditure over loans, to the extent of £22,696, has to be sanctioned, in order to put the matter upon a proper footing. The way will then be clear for an application for sanction to further loans in the ordinary way. Most of the excess is represented by an overdraft at the bankers.

WIMBLEDON: *Electricity Accounts.*—The accounts of the electricity undertaking for the past year show that although the receipts were considerably more than in previous years, there was a decrease of £150 in the profits. This was caused by the increased price of coal, increased rates and taxes, and by the fact that nearly £1,200 more was absorbed in repayment of loans than in previous years.

Water Supply.—The Electric Lighting Committee has decided that the construction of a weir across the river Wandle, at an estimated cost of £150, be proceeded with for the purpose of improving the supply for condensing water to the electricity works.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERDEEN.—Expenditure to the extent of £6,681 is to be incurred in connection with the supply of electricity to the districts of Woodside, Old Aberdeen, and Bucksburn.

The Electricity Committee has decided to recommend the Corporation to proceed with an extension of the electricity works, without delay, at an estimated cost of £16,000.

BOURNEMOUTH.—The Electrical Engineer recommends the installation of additional generating plant in the tramway power station.

DERBY.—A Local Government Board inquiry was held last week at the Guildhall, Derby, into an application by the Corporation for sanction to borrow £7,500 for the purposes of the electrical undertaking. Of this amount £5,750 is for mains and services, and the remainder for motors, transformers, radiators, and arc lamps.

DUBLIN.—The Lighting Committee has recommended that a

Digitized by Google

loan of £10,000 be applied for in connection with the further extension of the electric lighting plant.

GRIMSBY.—An additional feeder for supplying the Great Central Railway Co. with current at the docks is to be laid at an estimated cost of £175.

HORNSEY.—The Borough Council is to extend its mains from Turnpike Lane along Wightman Road at an estimated cost of £370.

LEYTON.—Sanction has been received from the Local Government Board for the borrowing of £895 for the provision of additional plant for the tramways.

LONDON COUNTY COUNCIL.—Tenders are invited for (*a*) the supply and delivery of low-tension cables, cable boxes, and other material required for the wiring and fitting for electric lighting and for power purposes of the electricity generating station at East Greenwich, and the central car repair depôt, Woolwich Road, S.E.; (*b*) for the wiring and fitting for electric lighting of the central car repair depôt; (*c*) for the supply, delivery, and erection at certain of the Council's tramways sub-stations of high- and low-tension switchgear; and (*d*) for the supply, delivery, and erection of six 500-kw. and one 150-kw. motor generators. Full particulars from the Clerk to the Council (fee, £2 for each specification, returnable), and tenders by September 8th.

REIGATE.—Tenders are invited for the supply and erection of a complete surface condensing plant with cooling tower, &c. Full particulars from the Electrical Engineer (fee, £1 1s., returnable), and tenders to the Town Clerk by August 20th.

SALFORD.—On Tuesday Mr. Tulloch, of the Local Government Board, held an inquiry at the Town Hall, *re* an application by the Corporation for sanction to borrow £15,281 for the purposes of the electricity undertaking. It was stated that the amount was required as follows:—£11,707 for cooling plant; £575 additional expenditure on the turbo-generating plants, and £3,000 for the extension of the Prestwich lighting system, over which the borough had control.

ST. ANNES.—The Local Government Board have sanctioned the borrowing of £3,500 for mains extensions.

SOUTHAMPTON.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £3,000 for the purposes of the electric lighting undertaking. The loan is for prospective expenditure upon new mains and services.

STRETFORD.—Tenders are invited for the following work in connection with their electrical undertaking:—Contract No. 27, steam boilers and accessories. Contract No. 28, economisers and accessories. Contract No. 29, mechanical stokers. Forms of tenders, &c., from the Town Clerk (fee one guinea, returnable in each case), and further particulars from Mr. T. L. Miller, 19 Brazennose Street, Manchester. Tenders to the Town Clerk by August 24th.

WHITEHAVEN.—A Local Government Board inquiry was held last week at the Town Hall with reference to an application by the Corporation for sanction to borrow £1,700 for electrical purposes.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Rebuilding of premises of T. Venables & Sons, drapers and furnishers, 103–115, High Street, Whitechapel.

Additions to St. James's Schools, Forest Gate. Architects, Newman & Jacques, 2 Fen Court, E.C.

Wesleyan Sunday Schools at Canning Town. Architects, Withers & Meredith, 50 Cannon Street, E.C.

Stores, Stables, &c., at Stratford. Architect, W. Stewart, 4 Aldgate, E.

Additions to premises at Stratford of Young & Martin. Architect, P. H. Adams, 65 Leadenhall Street, E.C.

Alteration of premises in Aldgate for provision importers. Builders, Vigor & Co., King Street, Poplar.

Additions (£1,350). Custom House School. Builder, H. C. Horswill, 182 Green Street, Forest Gate, E.

E.C.—Extension of premises by J. Buchanan & Co., distillers, 26 Holborn, E.C.

N.—Eighteen houses and one shop at Muswell Hill. Architect, W. J. Keith, 7 East India Avenue, E.C.

Fifteen houses, Hornsey. Architect, John Farrer, 2 Coleman Street, E.C.

Premises in High Street, North Finchley, for London & South-Western Bank, 170 Fenchurch Street, E.C.

St. Alban's R.C. Church, Finchley, for the trustees.

Additions to Convent Laundry, Highgate. Builders, E. Kerry & Sons, 63 High Street, Highgate.

Eight houses, Finchley. Builder, C. W. Scott, Church End Station, Finchley.

Three houses, Finchley. Builder, J. Chillingsworth, Bibsworth Road, Finchley.

Two houses, Stroud Green. A. W. Jones, North Finchley.

Gymnasium at Muswell Hill. Builders, T. D. Steed & Sons, 2a, Langdon Place, N.

Moravian Sunday School, Hornsey. G. Mabey & Co., Upton Manor, N.

N.E.—Rebuilding of business premises in High Street, Shoreditch. Builders, J. Haydon & Sons, Teesdale Street, Hackney Road, N.E.

N.W.—Proposed extension of tramway depôt. Collindale, Chief Engineer, Metropolitan Electric Tramways, 4 South Place, E.C.

S.W.—Development of new road, Putney. Architect, J. C. Radford, 223 Upper Richmond Road, Putney.

W.—Buildings in Askew Road, Hammersmith. Architect, J. J. Kelf, 215 Hoe Street, Walthamstow.

Adaptation of Stratford House for Lord Derby. Lofts & Warner, Estate Agents, 130 Mount Street, W.

Buildings in Berkeley Street, Piccadilly. Builders, Patman & Fotheringham, Islington.

Shops and showrooms, Great Portland Street. Architects, J. W. Simpson & M. Ayrton, 3 Verulam Buildings, Gray's Inn, W.C.

W.C.—Offices in Aldwych for insurance company. Marler & Marler, surveyors, 176 Sloan Street, S.W.

Alterations, Adelphi Restaurant, Strand, to fit as public offices, Sir Horace Tozer, Agent-General for Queensland, 1 Victoria Street, S.W.

PROVINCES.

BARKING.—Hospital buildings for District Council. Architect, C. J. Dawson, East Street, Barking.

BEDFORD.—Offices for County Council (£2,650). W. W. Marks, Clerk, Shire Hall, Bedford.

BOLTON.—Restoration St. George's Church. Architect, J. L. Simpson, Bolton and Liverpool.

BURTON-ON-TRENT.—Police station and court-house. Architect, Hy. Beck, 30 High Street, Burton-on-Trent.

EASTBOURNE.—Alterations, business premises. Architect, F. G. Cooke, 3 Hyde Gardens, Eastbourne.

EAST HAM.—Rebuilding "Red Lion" public-house, High Street.

Extension of Liberal Club. J. H. Carte, "Knighton," Aldersbrook Road, Ilford.

GRAVESEND.—School (£9,350). Architect, J. J. Robson, 335 High Holborn, W.C. Builder, G. Gates, Frindsbury, Rochester.

HULL.—Completion (£25,170) City Hall. Architect, J. H. Hirst, City Hall, Hull. Builder, W. Sanderson, Temple Street, Hull.

ILFORD.—Hospital. Architects, Armstrong & Wright, 38 Grainger Street West, Newcastle-upon-Tyne.

MANSFIELD.—Additions to Braemhill Schools (£3,100). Architects, Vallance & Westwick, White Hart Chambers, Mansfield.

RAWTENSTALL (Lancs.).—Weights and Measures Office. H. E. Clare, clerk, County Council, Preston.

RICHMOND.—Development Selwyn Estate. Worsfold and Hayward, surveyors, 80 Cannon Street, E.C.

Alterations to Richmond Theatre.

Business premises, North Road, Richmond. Architect, W. Vincent, 3 West Park Crescent, Kew Gardens.

ROTHERHAM.—Secondary school (12,287). Builders, H. Arnold & Son, Doncaster.

SALFORD.—Baths in White Street. Architects, Mangnall & Littlewoods, 42 Spring Gardens, Manchester.

Alterations to St. James's Hotel, St. James's Street.

SOUTHAMPTON.—Fire station (£4,210). J. A. Crowther, Borough Engineer. Builders, Dyer & Sons, Bevois Hill, Southampton.

WALSALL.—Additions to "The Four Horse Shoes," for the Wolverhampton and Dudley Brewery Co.

Additions to Mission Church for the Church Council of St. John's, The Pleck.

WIGAN.—Circus and Assembly Hall in Library Street, for J. Worswick & Sons.

WIMBLEDON.—Extension of Technical Institute.

Conversion of St. George's College into Pension. Architect, R. A. Hinds, Wood Nook, Wimbledon Hill.

Residence and motor-house. Surveyors, Boyton, Sons & Trevor, 70 Coleman Street, E.C.

Twenty-nine houses, Melrose Avenue. C. Barwell, The Elms, Merton, Wimbledon.

Shop and showrooms. Builders, Whitehead Bros., 21 Hill Road, Wimbledon.

WINCHESTER.—Offices for County Council. Consulting Architect, T. G. Jackson, 14 Buckingham Street, Strand, W.C.

Lamps, Public Lighting, and Miscellaneous

BOLTON.—The Electricity Committee invite tenders for the supply of 25,000 tons of bituminous engine slack to be delivered at the electricity works, Spa Road. Tenders have to be in by noon on August 27th.

KINGSTON.—The Works Sub-Committee of the Town Council have been requested to consider the question of the lighting by electricity of the public lamps in Canbury Gardens.

PORTSMOUTH.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £5,000 for public lighting purposes. During

Digitized by Google

the course of the inquiry Mr. F. A. Tulloch, the inspector, said that he had investigated the expenditure of certain amounts upon incandescent street electric lighting, and was inclined to think that this was an extravagant means of illumination in comparison with the cost of gas lighting in the town. Mr. W. S. Foale, the electrical engineer, pointed out that it was in consequence of the previous expenditure upon incandescent electric street lamps that the Gas Co. reduced their charges by 5s. per lamp per annum, and thus showed a considerably cheaper method of illumination. In the present case, however, metal-filament lamps would be used, which would considerably reduce the charges for current.

SPAIN.—Tenders are invited for the supply of four electric cranes at Huelva. Tenders, Huelva, September 6th. A deposit of 5 per cent. of the value of the tender (which must be increased to 10 per cent. if the tender be accepted) will be required. A copy of the form of tender and other general information may be seen at the Commercial Intelligence Branch of the Board of Trade.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Victorian Postmaster-General's Department has accepted the following tenders:—300 counters for switchboards, at 7s. 3d. each, £108 15s., the India Rubber, Gutta Percha, and Telegraph Works Co., Melbourne; 3 cable waggons, at £16 5s. each, Wearne Brothers, Port Melbourne; 125 translators, telephone, ordinary, at 11s. 8d. each, 50 translators, telephone multiplex, at 12s. each, 100 telephone attendants' head and breast telephone sets, at 36s. each, J. Bartram & Son, King Street, Melbourne; one mile of 50-pair silk and cotton insulated telephone switchboard cable, £190, one mile of 100-pair silk and cotton insulated telephone switchboard cable, £565, British Insulated & Helsby Cables, Melbourne.

BRIGHTON.—The tender of Messrs. Siemens Bros and Co. for cable and pilot wire, in connection with the supply to the London, Brighton & South Coast Railway Co.'s works, at £3,194 and £57 10s. respectively, has been accepted.

FINCHLEY.—The Council has accepted at £964 the tender of Mr. A. E. Faulks for extending the engine-house at the generating station.

FULHAM.—The Electricity Committee has accepted the tender of G. Aldington, Wimbledon, at £12, for repairs to the destructor shaft.

MANCHESTER EXHIBITION.—Messrs. Ward & Goldstone have received a contract for the supply of wires and cables for the Electrical Exhibition in Manchester, through Messrs. Lomax Kendal & Co., who are the contractors.

ROTHERHAM.—The Council has accepted the tender of the Worthington Pump Co. for an electrically-driven pump at £283.

SALFORD.—The Council has accepted the tender of the Blasberg Engineering Co. at £11,457 for the supply and erection of a water-cooling plant; also the tender of Waring & Gillow, Ltd., at £344 for re-wiring portion of the Royal Technical Institute.

THIRSK.—A contract has been entered into with the Northern Counties Electricity Supply Co. for public lighting for three years at £205 per annum.

WALSALL.—The Electricity Committee has decided to purchase a 3-in. Venturi water meter from George Kent, Ltd., for measuring water from the canal in connection with new condensing plant at £70. The tender of Jesse Tildesley, Ltd., at £18 10s. for steel girders for the cooling tower and purifier foundations has been accepted.

WIMBLEDON.—An offer of the British Electric Transformer Co., Ltd., to supply two 50-kw. transformers in exchange for five disused transformers and the payment by the Council of £66 has been accepted.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire-bars, net c.i.f. port of arrival, quoted on Tuesday night was £64 to £64 10s. per ton (last week £61 5s. to £61 15s. per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the creditors of the Easton Light Co., Ltd., will be held at Broad Sanctuary Chambers, Westminster, London, on August 18th, at 4 p.m. Creditors desiring to be present should communicate with the liquidator, Mr. L. Philips, at the above address.

Creditors of the Seville Tramways Co. are requested to send particulars of their claims to the liquidator, A. F. Judd, 2 Broad Street Place, Finsbury Circus, London, by September 8th.

LEA RECORDERS.—Among recent orders for these recorders, which are made by Mr. James E. Lea, 46 Brown Street, Manchester, are: One for the Derby Corporation Electricity Works, one for Messrs. Bolckow, Vaughan, & Co., six for the London County Council, and one for the St. Pancras (London) Borough Council.

COMPANY MORTGAGES, &c.

BRITISH ELECTRIC TRACTION COMPANY.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date, and not required to be registered under Section 14 of the Companies Act, 1900, has been filed. Particulars—Floating charge on the company's undertaking and property, present and future, including uncalled capital, dated June 30th, 1898, securing £1,473,653 perpetual debenture stock, in favour of the Electric & General Investment Company, Ltd.

GUILDFORD ELECTRICITY SUPPLY CO.—Particulars of £25,000 debentures, created by resolution of November 21st, 1905, have been filed pursuant to section 10 (3) of the Companies Act, 1907, the amount of the present issue being £200. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees.

REASON MANUFACTURING CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Trust deed, dated December 18th, 1900, securing £25,000, charged on certain lands in Preston, Brighton, with factory and other buildings thereon and company's general assets.

SWITCHGEAR COMPANY (BIRMINGHAM).—A trust deed dated June 30th, 1908, to secure £2,000 debenture stock, charged on the company's property, has been registered. Holder—J. Sermon, 140 Eccles New Road, Weaste, Manchester.

SWITCHGEAR CO.—Second Debenture, dated July 7th, 1908, to secure £2,000, charged on company's property, present and future, including uncalled capital, has been registered. Holders—Cowans, Ltd., 4 Queen Victoria Street, E.C.

MISCELLANEOUS CITY NOTES

AMERICAN TELEPHONE & TELEGRAPH CO.—Messrs. Baring Bros. & Co., Ltd., are prepared to buy the coupons of the 4 per cent. convertible gold bonds falling due on September 1st, at the current rate of exchange.

COMPANIES STRUCK OFF REGISTER.—Notice is given that the names of the following companies, among others, will be struck off the register at the end of three months, and the companies dissolved, unless cause is shown to the contrary:—Accumulator Syndicate; Dorchester and District Electric Supply Co.; Kingsbridge and South Devon Electric Lighting and Traction Co.; Penarth Tramway Syndicate.

ELECTRIC SUPPLY CO. OF VICTORIA.—The directors recommend a dividend of 6 per cent. on the preference shares for the past year, carrying forward £782.

MARCONI'S WIRELESS TELEGRAPH CO.—The share certificates for the 7 per cent. cumulative participating preference shares are now ready, and may be had on application at the office of the Company, Watergate House, Adelphi, London, W.C., in exchange for bankers' receipts for payments on application and allotment.

MATHER & PLATT.—An interim dividend on the ordinary shares of 5 per cent., free of tax, for the half-year ended June 30th, being at the rate of 10 per cent. per annum, has been announced.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAYS CO.—The directors have declared an interim dividend of 5 per cent. per annum, less tax, on the ordinary shares for the past half-year.

OXFORD ELECTRIC CO.—An interim dividend of 5 per cent. per annum, less tax, has been declared upon the ordinary shares for the past half-year.

POWER GAS CORPORATION.—The capital of this company has been reduced from £350,000 to £300,000, divided into 250,000 ordinary shares of £1 each and 100,000 deferred shares of £1 each.

SIR W. G. ARMSTRONG WHITWORTH & CO.—An extraordinary general meeting was held on Friday, when an issue of £1,000,000 4 per cent. debenture stock was authorised. This stock has been sold *en bloc* to the Law Debenture Corporation, who have offered it to the public at 102½.

APPOINTMENTS AND PERSONAL NOTES

As a compliment to the mains superintendent, Mr. Mackay, on the occasion of his marriage, the Aberdeen Corporation Electricity Works Department gave a smoking concert on Friday, the chair being occupied by Mr. J. A. Bell, the City Electrical Engineer. A presentation was made to Mr. Mackay.

Mr. J. Slevin, the electrical and tramways manager of the Wigan Corporation, has, it is stated, in consequence of being relieved of a portion of his duties in the tramways department through the appointment of a traffic manager, intimated his willingness to accept a reduction of £50 in his present salary.

The salary of the Electrical Engineer to the Eccles Corporation, Mr. H. Angus, has been increased from £250 per annum to £350 per annum.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

BAKER STREET AND WATERLOO RAILWAY CO.—At the half-yearly meeting on Monday, Sir George Gibb, the Chairman of the company, presiding, the report and accounts given in our last issue were adopted. The Chairman congratulated the proprietors on the very satisfactory progress of the undertaking. For the first time they had entered the ranks of dividend-paying railways, being able to pay not only the full 4 per cent. on the preference stock, but also, out of their own resources, a dividend at the rate of ¾ per cent. per annum on the whole of the ordinary shares. He believed that in the four half-years since the railway was opened the railway had shown a larger percentage growth in business than had previously been shown by any Tube railway undertaking, and this must be regarded as a most encouraging feature. During the June half-year they had carried nearly 13 million passengers, an increase of three millions, or a little over 30 per cent., as compared with the corresponding six months of 1907. The explanation of the relatively good growth in their traffic was, he thought, to be found in the location of the railway, which had created an entirely new facility to travel, and did not depend, as many new lines did, on the diversion of traffic from any other railway route. The development of through traffic was especially satisfactory. They had through bookings with nine different companies, and out of a total traffic of about 13 million passengers, about 4,750,000, or 36 per cent., had been passengers travelling with through tickets. The through traffic exchanged with the Central London Railway amounted to 40,000 passengers per week. Their exchange with the Piccadilly Tube had been 55,000 per week, and with the City and South London about 30,000 per week. He watched the development of this through traffic with great interest, because it was undoubtedly in the general development of traffic movement, not on one line only, but on all lines, and by close harmony of working and co-operation in advertising and in working, that the best hope for the prosperity of the urban railways in London lay. He sincerely hoped that the era of narrow jealousy and foolish fighting had passed away. They must, however, be content with a smaller yield from a through passenger than they got from a local passenger. On the "Bakerloo" Railway the average fare from local passengers, including workmen, was 1·55d., while their average receipt from their proportion of through traffic was only 1·56d. per passenger. The balance available for dividend, apart from the payment by the Underground Company under their guarantee, was £20,892, and the Board recommended a dividend declared at the rate of 4 per cent. per annum on the preference shares and a dividend at the rate of ¾ per cent. per annum on the ordinary shares. The Underground Company held all the ordinary shares except £298,030. They had guaranteed a dividend at the rate of 5 per cent. per annum on the whole capital until the Paddington extension had been either completed or abandoned, and under this guarantee they paid for the past half-year £2,142, which payment, together with the balance of net revenue available, made up the dividend on the shares held by the public to the rate of 3 per cent. per annum. With regard to the Paddington extension, the directors were not yet prepared to make a definite recommendation. The matter was still under the consideration of the Board, who hoped to be in a position to make a recommendation on the subject at the next half-yearly meeting.

BLACKWOOD & FLEETWOOD TRAMROAD CO.—The report for the half-year to June 30th states that, including the sum brought forward, there is a profit of £3,662 after providing for debenture interest. The directors recommend a dividend of £4 per cent. per annum, which will absorb £3,000 and writing off £500 to depreciation reserve, carrying forward the balance of £162. The number of passengers carried during the half-year was 899,346. The meeting is on the 26th inst.

CENTRAL LONDON RAILWAY CO.—At the half-yearly meeting on Thursday the report and accounts given in our last issue were adopted. Sir Henry Oakley, the Chairman, who presided, said that the undertaking had been completed by the construction of the line at Shepherd's Bush from the down road round the yard into the up road, so as to make a continuous working, and advantage had been taken of the opportunity to establish a station exactly opposite the entrance to the Franco-British Exhibition, which had been of the greatest possible use, and had earned its living most handsomely. The expenditure on capital account had been very small. On the line and station they had spent £58,650, and on additional generating plant £11,048. The financial position of the company was quite simple. There were powers for about £240,000 yet unexercised, and the expenditure on capital account was £113,000 in excess of their money. They had probably £50,000 more to spend, so that there were £145,000 of liabilities to be paid out of £224,000. They had, therefore, a margin of £81,000. Dealing with the revenue for the half year, the chairman briefly put the history as follows:—For the first four months, up to the end of April, there was a decline in the daily receipts and in the number of passengers. There is no doubt that this traffic was the short distance traffic, and the only way to meet it would have been, of course, to have rearranged their fares, but on considering it carefully the Board had determined to test the working for a year before making any alteration. On the opening of the exhibition on May 14th, however, passengers increased daily, and in six weeks they got 676,000 more passengers than in the corresponding period of last year. In reply to questions, the chairman said he was not in a position to state that there would be an exhibition at Shepherd's Bush next year, but they were given to understand that the promoters were endeavouring to arrange for its continuance next year in some form or another.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—At the half-yearly meeting on Tuesday, Sir George Gibb, Chairman of the company presiding, the report and accounts given in our last issue were adopted without comment.

CHATHAM AND DISTRICT LIGHT RAILWAYS CO.—The result of the half-year's working to June 30th shows receipts amounting to £19,061 and expenses to £12,433. Deducting rent of Rochester Corporation lines, interest on debentures, interest on loans, &c., and expenditure on lines abandoned, there is a balance of £4,086, to which has to be added the balance brought forward from December 31st, 1907, viz., £348, leaving a balance of £4,434 available for distribution. The directors recommend a dividend of 5 per cent. per annum on the preference shares, carrying forward £1,494. The directors regret that, owing to continued trade depression in the Chatham district, the revenue for the half-year has been very disappointing. The Rochester Corporation extension lines to Strood Hill and Frindsbury were opened at Easter and leased to the company. Satisfactory arrangements were made for the supply of current for these extensions from the Kent Electric Power Co. During the half-year the loan of £2,500 from the company's bankers has been repaid. The directors will, as usual, provide for depreciation when the final accounts are made up at the end of the year. The meeting is on the 21st inst.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—The report for the June half year states that, after providing for debenture interest there is an available balance of £868, out of which the directors recommend the payment of the usual half-yearly dividend on the 5 per cent. preference shares, which will absorb £475, and that the balance of £393 be carried forward to next half-year.

EDMUNDSONS' ELECTRICITY CORPORATION.—The Directors' report for the year ended March 31st, 1908, states that the net profit after payment of debenture interest amounts to £2,610, which, with the sum of £17,807 brought forward from last year, makes a total of £20,417. The directors recommend that this amount should be carried forward to the next account. The loss on working the local authority undertakings has this year, in addition to the net amount of the urban company guarantee, been deducted from the gross trading profit and shown on the profit and loss account. The diminished return shown on loans and investments is entirely attributable to the fact that a much larger provision for reserve and depreciation has been made by the subsidiary companies, an additional amount of over £12,000 having been so set aside, of which over £10,000 is apportionable to the Corporation's holdings in these companies. The directors believe that this more liberal application of profits to these purposes is calculated to enhance the credit and strengthen the position of the Corporation no less than that of the subsidiary companies, whilst the money is equally available for capital purposes, whether it is so dealt with or whether it appears in the Corporation's accounts. Although not apparent on the face of the accounts, which can only reflect improvement in the accounts of the subsidiary companies to the extent to which those companies make larger dividend distributions, the directors are satisfied that the position is better than it was a year ago, and that there is evidence of its steady improvement. The gross profits of the subsidiary companies have increased during the year by £9,433, the amount expended on capital account during the year being £69,065. This compares with £92,760 for the previous year. The reduction of £40,926 in the item of investments and advances to subsidiary companies is accounted for by a reduction in the amount of the advance to the urban company consequent upon the issue of £75,000 debenture stock by that company. A sum of £1,491 has been added to the reserves, which now amount to £183,564. As the shareholders are aware, the report of the committee appointed at the last annual general meeting was adopted by the shareholders at the extraordinary general meeting held for the purpose in February of this year. The committee's report included recommendations for the appointment of the present board and for the creation of £200,000 prior lien debenture stock. The consent of the debenture stockholders to the immediate creation of £100,000 5 per cent. prior lien debenture stock was subsequently obtained, and that amount of stock has accordingly been created and recently issued. The proceeds of this issue are expected to provide for the Corporation's capital requirements during the next two years, and the directors believe that this provision will go far towards safeguarding the financial position of the Corporation. Mr. F. E. Gripper has resigned his position as managing director, and is now the general manager of the company. Mr. Stanley Beeton was appointed to a seat on the board in accordance with the recommendations of the committee above referred to, and the shareholders will be asked at the meeting to confirm

Digitized by Google

this appointment. Mr. P. D. Tuckett retires by rotation and offers himself for re-election.

At the meeting on Thursday, the report of the accounts was adopted. The Chairman, Mr. P. D. Tuckett, said that the reduction shown in the trading profits for the year was accounted for mainly by the smaller turnover, and by the fact that the local authority losses had been charged directly against the profit instead of to reserve, as formerly. He believed that with care and prudence they would recover part of their money, and the directors were not going to jeopardise the future by reserving dividends unless the position warranted it. No doubt they had a long and uphill road to travel before they would be again in sight of dividends, but his opinion was that there was nothing to warrant the impression that the electric supply industry was retrograding.

GREAT NORTHERN & CITY RAILWAY CO.—The Earl of Lauderdale presided over the half-yearly meeting last week, when the report and accounts given in our issue for August 6th were adopted. The greater portion of the chairman's speech was devoted to the falling off in traffic, viz., 1,393,835 passengers, as a consequence of which the revenue had decreased by £5,364. He said this was due mainly to the competition of the London County Council electrified tramways and in some degree to the alteration of certain fares, as from November 1st, 1907, but the additional revenue from increased fares had undoubtedly compensated to a great extent for the heavy loss in passengers. Nearly half the loss of traffic had occurred between Highbury and Moorgate, where they had so far felt the tram competition most severely. The Board had done their best to meet this competition by speeding up the trains, and by running non-stop trains. Referring to the recent fire at the Moorgate Station of the City and South London Railway, the chairman stated that it was hard to find anything on their system that was combustible, and altogether it could be taken that they were practically immune from fire risks.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—At the half-yearly meeting on Tuesday, Sir George Gibb, Chairman of the company presiding, the report and accounts given in our last issue were adopted. The Chairman said that this railway was not only a new undertaking, but was what might be called a new route, a condition which meant that traffic had to be developed and was longer in coming than over a route already served by other means of communication, but the growth continued for a longer period. This being so, he thought the growth of the traffic up to date had been unusually rapid. They were only in their third half-year, but had carried 17½ million passengers, which was an increase of 5½ millions compared with the corresponding period of 1907. The permanent way and car equipment was proving excellent, and he thought it was lasting better than on any other London railway with which he was acquainted. The total expenditure had been 4·81d. per car mile, including rates and taxes, or 1·03d. per passenger. They were able to declare a dividend of ¾ per cent. upon the whole of the paid up capital of the company.

GREAT WESTERN RAILWAY CO.—The report for the June half-year shows that the cost of electric train working has been £13,778, compared with £11,382 for the corresponding period of 1907. The total is made up as follows:—wages of train men, £1,669, electric current, £8,309, oil and stores, £981, repairs and renewals, £3,109. The train mileage of electric cars during the half-year was 189,161, compared with 157,958 for the June half-year of 1907. At the meeting on Tuesday the report and accounts were adopted.

LANARKSHIRE TRAMWAYS CO.—The result of the half-year's working to June 30th shows receipts amounting to £33,960 and expenses to £18,992. Deducting contributions payable to local authorities, interest on debentures, and interest on loans, there is a balance of £13,125, to which has to be added balance brought forward from December 31st, 1907, viz., £895, leaving a balance of £14,020 available for distribution. The directors recommend a dividend of 6 per cent. per annum for the half-year on the share capital issued prior to January 1st, 1908, and a dividend of 6 per cent. per annum on the new issue of 2,077 shares from date of payments of the instalments to June 30th, 1908, carrying forward £5,155 to revenue new account. The directors have pleasure in reporting that the traffic receipts have again been very satisfactory, exceeding by over £4,000 the receipts for the corresponding half-year of 1907. Although the expenses have been very heavy, owing to high prices for coal and legal charges in opposition to Parliamentary Bills affecting the company's interests, the profit available for distribution after reserving £1,117 15s. for contributions to local authorities, as compared with £621 10s. last year, is sufficient to pay a dividend at the rate of 6 per cent. for the half-year as against 5½ per cent. at June 30th, 1907, and to carry forward approximately the same amount. The directors will, as usual, provide for depreciation when the final accounts are made up at the end of the year. During the half-year the balance of the loan from the company's bankers, viz., £7,500, has been repaid. The 2,077 shares offered to the shareholders in February last were subscribed for in full. The proceeds have been utilised in constructing the two extensions referred to in the previous report and the purchase of seven additional cars. The directors regret that, owing to delays in passing the plans by the local authorities and late delivery of certain materials, the lines were not opened as early as anticipated. As the company's plant is already working at full load, negotiations are pending for the supply of current in view of the above extensions, which will obviate for the present further capital expenditure on power station plant.

LIVERPOOL OVERHEAD RAILWAY CO.—At the half-yearly meeting on Tuesday, the report and accounts, given in our last issue, were adopted. Sir W. B. Forwood, who presided, said that the company had, in common with others, felt the stress of the great depression in trade, yet it was difficult to see how the trade of the port at Liverpool could be conducted without their railway. So much so, in fact, that he often thought the company had a claim on the Dock Board of a subsidy. There was no prospect of it at present however.

LONDON, BRIGHTON & SOUTH COAST RAILWAY CO.—At the meeting of the London, Brighton & South Coast Railway Co. on Wednesday last week it was stated that the conversion of the lines between London Bridge and Victoria to electric traction was proceeding rapidly, and experimental running between Peckham Rye and Battersea Park would be commenced before the end of the year.

MIDLAND RAILWAY CARRIAGE & WAGON CO.—The accounts for the year to June 30th show a gross profit of £55,594. £4,000 have been set aside for depreciation, and £5,000 were absorbed by the interim dividends. The directors now propose to pay a dividend on the ordinaary shares at the rate of 7½ per cent., free of tax, and a bonus of 10s. per share free of tax. £5,000 are to be added to reserve fund (bringing this to £115,774), and £4,152 are carried forward.

NORTH-EASTERN RAILWAY CO.—The half-yearly report to June 30th shows that the number of car-miles travelled by the electric passenger trains of the company during that period was 1,840,161, against 1,861,415 in the corresponding period of 1907. The cost of the electrical energy purchased was £12,224, against £13,048 in the June, 1907, half-year, and the wages of trainmen amounted to £3,699, against £3,853.

NORTH LONDON RAILWAY CO.—At the half-yearly meeting last week it was stated that competition of the Great Northern and City Tube Railway and the electric tramways continued to increase, and no relief in this respect was to be anticipated.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The transfer register and register of preference shareholders will be closed from August 18th to 31st, 1908 (both days inclusive) for preparation of warrants for the interim dividend for the half-year ended June 30th, 1908.

TYNESIDE TRAMWAYS & TRAMROADS CO.—The directors' report for the half-year ending June 30th, 1908, shows a surplus of receipts over expenses of £3,242, which, with the balance brought forward from last half-year makes a total available of £3,665, and after deducting interest on debentures, loans, &c., amounting to £1,209, there remains a balance of £2,456. This profit the directors propose to appropriate as follows:—Dividend on preference shares at the rate of 5 per cent. per annum (less income tax), £497; to the credit of reserve for renewals, depreciation, and other contingencies, increasing this to £5,500, the sum of £900; proportion of registration and formation expenses, £330; leaving to be carried forward to next half-year £728. The decreased profit for the half-year, as compared with the corresponding period of last year, is entirely consequent upon the reduction in receipts, amounting to £1,251, against which the reduction of running expenses is only £18. This falling-off in revenue is attributable to the smaller traffic on the company's lines, caused by labour troubles and the depression in trade which have been prevalent in the district during the period. Of the unissued preference shares, 27 were applied for and allotted during the half-year, and a further 50 have been applied for since June 30th, thus leaving 890 still unissued. The consols held in respect of Parliamentary deposits have been released and are now retained as an investment of the reserve fund.

YORK UNITED GAS LIGHT CO.—At the half-yearly meeting last week the Chairman stated that at the recent inquiry into an application by the York Corporation for borrowing powers for electrical extensions, it was brought out that the cost to the ratepayers of the public electric lighting was very considerably more than that of the displaced gas lighting. Wherever an impartial judgment could be brought to bear upon the merits of the rival illuminants it was conceded, said the Chairman, that gas was much more efficient and suitable for street lighting than electricity.

PARA ELECTRIC RAILWAYS & LIGHTING CO.—The annual general meeting was held in London last week. Sir W. Evans-Gordon, Chairman, who presided, said that the construction of the railways did not begin until August 15th, 1906, and the contractors, Messrs. J. G. White & Co., has been confronted from the outset with many difficulties. These had been overcome, however, and the whole system of about 35 miles of single track had been converted, and all the mules and horses had disappeared. The equipment consisted of 68 cars, in addition to a number of old cars converted for use as trailers. The report and accounts dealt with the year ended November 30th, 1907, and therefore covered the time when confusion and disturbances arising from the reconstruction were at their highest. The present company had only been in possession of the undertaking for two years, and the receipts for the year ended

Digitized by Google

November 30th, 1906, amounted to £136,166, and in 1907 to £137,098, whilst from the lighting business the receipts had been £65,728 and £67,485 respectively. With regard to the supply of electricity, the demand had increased beyond the capacity of the company's station, and a new 450 kw. generating set was shortly to be installed. After full consideration, the directors had decided to replace the old overhead feeders by underground cables, and they believed that this outlay would be justified. On the past results of the undertaking, it was estimated that the gross receipts for the first complete year under electrical working to December, 1908, would be £220,000, from which would have to be deducted estimated working expenses of £132,000, these being taken at 60 per cent. of the receipts. After deducting London and general expenses, interest and redemption of debentures and preference share dividends, it was calculated that there would be £28,000 for depreciation, reserve and dividends on the ordinary share capital. The report and accounts were adopted.

NEW COMPANIES

CERTUS GEARLESS CO.—This company was registered on July 24th, with a capital of £25,000 in £1 shares, to acquire the assets and liabilities of the "Certus" (Gearless) Co., Ltd., to adopt an agreement with the said old company and the liquidator thereof, and to carry on the business of mechanical, electrical, sanitary, gas, and water engineers, makers of electrical tramcars, motor-cars, carriages, cycles, and other vehicles, manufacturers of engines, machines, &c. The subscribers are:—Sir James H. Renals, Bart., C. Nathan, A. C. Godwin-Smith, E. Gillett, D. C. M. Hume, J. W. M. Rogers. Minimum cash subscription, £6,400 The number of directors is not to be less than three nor more than seven; the first are the Right Hon. Earl of Kinnoull, D.L., J.P., Sir James H. Renals, Bart., and C. Nathan. Qualification, one share. Remuneration, £100 each per annum (chairman £150), and 10 per cent. of the profits available for distribution when 10 per cent. is paid, divisible. Registered office, 43-4, Great Windmill Street, W.

CORDOVA & NORTH WESTERN RAILWAY CO. (1908).—This company was registered on July 14th, with a capital of £100,000 in £10 shares, to acquire the concession from the province of Cordova for a railway from Cordova, passing by La Calera, along the River Primera to Dique de San Roque, through Cosquin, and thence to Cruz del Eje, and any branches or extensions thereof, to enter into a contract or contracts with any person or persons for the acquisition, completion, construction, and equipment of such railway, to enter into an agreement with the Cordova & North Western Railway Co., Ltd., to complete, equip, and work, by steam, electric, or other power, the said railway and any extensions or branches thereof, &c. The subscribers are: G. W. Grinnell-Milne, C. H. Sanford, G. Hannaford, T. Merrylees, A. Malden, G. Hassenden, and F. A. Kentfield. The number of directors is not to be less than three, nor more than six; the first are G. Grinnell-Milne, C. H. Sanford, and G. Hannaford. Qualification, 25 shares. Remuneration not more than £1,000 each per annum. The directors are specifically authorised to create £600,000 4 per cent. debentures. The amount which they may borrow on debentures or debenture stock, or otherwise, in addition to this £600,000, without the sanction of a general meeting, is left blank in the Articles of Association. Registered office, Salisbury House, London Wall, E.C.

COWEYS.—This company was registered on July 15th, with a capital of £6,000 in £1 shares, to adopt an agreement with L. E. Cowey, and to carry on the business of electrical, hydraulic, mechanical, manufacturong, civil, and mining engineers, founders, &c. The subscribers are: K. Houston, C. W. Inman, E. P. Barrington, B. B. Houston, W. P. Hunter, C. Brown, E. W. Church. Private company. The number of directors is not to be less than three nor more than five; the subscribers are to appoint the first. Registered office, 39 Victoria Street, Westminster.

"ELECTRICITY."—This company was registered on August 6th, with a capital of £1,000 in £1 shares, to acquire from C. A. F. Duranty the benefit of certain inventions relating to the production of electricity, and to carry on the business of electricians, engineers, suppliers of electricity for light, heat, power, or other purposes, &c. The subscribers are:—C. E. De Wolf, 27 Bidston Road, Oxton, shipowner; W. C. Bacon, 14 Cross Street, Manchester, shipowner; T. F. Harrison, 67 South John Street, Liverpool, shipowner; H. E. Fry, Godmanstone, Dorchester, gentleman; F. S. Watts, 7 Whittingham Avenue, E.C., shipowner; N. Denny, The Moat, Eltham, Kent, merchant; J. Rankin, 67 South John Street, Liverpool, shipowner. Private company. The number of directors is not to be less than three nor more than five; the first are C. A. F. Duranty and C. E. De Wolf, and the following nominees of C. E. De Wolf, viz.: W. C. Bacon, N. Dunn, and T. F. Harrison (all permanent). Table "A" mainly applies. Registered by Walker, Son, & Field, 61 Carey Street, W.C.

FOREIGN AND COLONIAL LIGHTING.—This company was registered on July 29th, with a capital of £30,000 in £1 shares, to carry on the business of engineers, producers of electric light or power, gas makers, and suppliers, &c. The subscribers are:—A. Herrmann, S. J. Wilkinson. Private company. The number of directors is not to be less than three nor more than five; the first are not named. Qualification, £250. Remuneration (except managing director), £150 each per annum (chairman, £200). Registered office, 58 Finsbury Pavement, E.C.

IRVINE GAS CO.—This company was registered in Edinburgh on August 1st, with a capital of £25,000 in £1 shares, to take over the business carried on by the Irvine Gas Light Co., and to supply gas, electricity, or other illuminant in the Burgh of Irvine. The subscribers are:—H. Lumsden, Castle Street, Irvine, solicitor; M. Watson, Bank Street, Irvine, cashier; R. Bremner, Bridgegate, Irvine, clerk; T. Miller, 15 Hill Street, Irvine, retired baker; B. Boyd, 170 High Street, Irvine, insurance agent; A. Walker, Bank Street, Irvine, gas manager; A. P. McLachlan, Seagate House, Irvine, solicitor. The number of directors is not to be less than five nor more than thirteen; the first are B. Boyd, A. Young, J. Gillies, R. Bremner, J. S. Gilmour, J. Johnston, A. R. Wilson, and M. Watson. Qualification 50 shares. Remuneration as fixed by the company. Registered office: 36 Cotton Row, Irvine, Ayrshire.

KITSON EMPIRE LIGHTING CO.—This company was registered on July 24th, with a capital of £100,000 in £1 shares (40,000 7 per cent. cumulative preference), to acquire from A. Kitson the benefit of certain patents and assets of the business carried on by him at 5 Hythe Road, Willesden, as the Kitson Light Foreign Supply Co., also to acquire from Empire Light, Ltd., of 100 St. Martin's Lane, W.C., certain patents for the invention known as the Empire Light, to adopt agreements: (1) with the said A. Kitson, and (2) with the said Empire Light, Ltd., and to carry on the business of manufacturers of lamps and stoves and other lighting and heating apparatus and plant, electrical, mechanical, and general engineers, &c. Private company, with three subscribers, viz.:—A. Kitson, 100 St. Martin's Lane, W.C., engineer; Scott Lings, 139 Cannon Street, E.C., merchant; and A. J. Hall, 19 Hammetton Road, Bromley, Kent, solicitor, taking one share each. The number of directors is not to be less than three nor more than seven; the first are A. Kitson (life director), and others to be appointed by the subscribers. The debenture holders have the right to nominate a director. Qualification (except debenture holders' director), £500. Remuneration (except managing directors), £50 each per annum (charge £200), and 5 per cent of the net profits available for distribution dividend.

LUX CANDLE CO.—This company was registered on July 14th, with a capital of £2,000 in £1 shares, to adopt an agreement with A. A. Barron, and to carry on the business of manufacturers of and dealers in electric candles, lights, and stoves, electric lighting and heating apparatus, batteries, dynamos, and switches, metal workers, electrical and general engineers, &c. Private company with only three subscribers, viz.: A. A. Barron, Cedarwood, Kidderpore Avenue, Hampstead, N.W., electrical engineer; A. Hooydonk, 11 Cork Street, W., decorative artist; and J. T. Brown, 29 Great Eastern Street, E.C., merchant, each taking one share. The first directors are A. A. Barron and A. Hooydonk. Remuneration, £50 each per annum.

NEWCASTLE-EMLYN AND DISTRICT ELECTRIC SUPPLY CO.—This company has just been registered with a capital of £2,000 in £1 shares, to generate, develop, and accumulate electrical power derivable from the falls of the River Tivy, and to carry on in Newcastle-Emlyn and adjoining districts the business of an electric light, heat, power, and supply company. The subscribers are:—T. J. Williams, J. R. Parkinson, W. Lloyd, A. P. Davies, J. E. Davies, W. E. Fuller, D. Jones. Minimum cash subscription, £1,300 The number of directors is not to be less than four nor more than seven; the first are not named. Qualification, £25.

PALVO CO.—This company was registered on July 30, with a capital of £3,000 in £1 shares, to adopt an agreement with H. Whitfield, and to carry on the business of dealers in dust-removing apparatus, electric or mechanical apparatus and other fittings, &c. The subscribers are:—H. Whitfield, Mrs. K. Whitfield. Private company. H. Whitfield is sole director. Qualification, 25 shares. Registered office, 10 Dane Street, Holborn, W.C.

SOLIUM ELECTRICAL CO.—This company was registered on July 28th, with a capital of £42,000 in 40,000 "B" shares of £1 each and 40,000 "A" shares of 1s. each, to carry on the business of manufacturers of and dealers in electrical, incandescent, filament lamps, electrical engineers and contractors, manufacturers of and dealers in electric, magnetic, and galvanic apparatus, &c., and to adopt an agreement with A. Hurter, J. McConnell, T. A. Hill, and E. Jardine. The subscribers are:—T. A. Hill, J. McConnell, J. W. McCraith, E. Harlow, A. Cherry, T. H. Smith, H. Atkin. Minimum cash subscription, £5,000. The number of directors is not to be less than three nor more than six; the first are T. A. Hill, J. McConnell, and E. Jardine. A. Hurter may, while holding 500 "A" and 5,000 "B" shares nominate a director. Qualification (except such nominee), £500. Registered by Jordan & Sons, Ltd., 116-17, Chancery Lane, W.C.

TANGITANA DEVELOPMENT SYNDICATE.—This company was registered on July 20th, with a capital of £2,000 in £1

Digitized by Google

shares (500 "A" and 1,500 "B"), to seek and secure openings for the employment of capital in Morocco and elsewhere, to carry on business as prospectors, miners, explorers, concessionaires, engineers, manufacturers of electrical and mechanical appliances, to erect electrical, gas, steam, pneumatic, or other installations, plant, and accessories for the supply of electricity or other power, &c. The subscribers are:—A. D. Bredenberg, H. J. Jones, H. T. Cornwell, J. L. Morris, S. T. Niell, J. P. Roe, H. Inchvald. Minimum cash subscription, 100 shares of either class. The number of directors is not to be less than three nor more than seven; the first are A. D. Bredenberg and H. J. Jones (both permanent), and H. T. Cornwell. Qualification 50 "A" or 100 "B" shares. Remuneration according to profits. Registered office, 72 Victoria Street, Westminster.

UNDERWOOD (MANCHESTER).—This company was registered on July 20th, with a capital of £3,000 in £1 shares, to adopt an agreement with W. G. Underwood, and to carry on the business of electricians, electrical, telephonic, and telegraphic engineers, fitters, &c. Private company, with two subscribers, viz.:—W. G. Underwood, 435 Chester Road, Old Trafford, Manchester, electrical engineer; and T. N. Underwood, 435 Chester Road, Old Trafford, manufacturers' agent, each taking one share. The number of directors is not to be less than three nor more than five; the first are W. G. Underwood (permanent, subject to holding 100 ordinary shares), and others to be appointed at statutory meeting. Registered office, 34 Pall Mall, Manchester.

WESTERN SHERARDISING CO.—This company was registered on July 22nd, with a capital of £20,000 in £1 shares, to acquire an exclusive licence for the counties of Cardigan, Pembroke, Carmarthen, Radnor, Brecon, Glamorgan, Hereford, Monmouth, Gloucester, Wilts, Somerset, Dorset, Devon, and Cornwall, to treat articles by certain processes for depositing metals on metals, known as the "Sherardising" and analogous processes, to adopt agreements: (1) with P. Dawson, and (2) with the Sherardising Syndicate, Ltd., and to carry on the business of galvanisers, zinc workers, steel and iron masters, blenders of alloys, &c. The subscribers are:—P. Dawson, R. Dawson, F. P. Bailey, C. E. Wilkey, W. J. Newall, J. W. Hinchley, W. K. Porteus. Minimum cash subscription, 5,000 shares. The number of directors is not to be less than three nor more than five; the first are W. J. Newall, W. W. Underwood, and P. Dawson. Qualification (except first directors), £100. Remuneration £50 each per annum, and 10 per cent. of the surplus profits remaining after 10 per cent. is paid, divisible. Registered by A. E. Hills, 6 King's Bench Walk, E.C.

YORKSHIRE CABLE CO.—This company was registered on July 28th, with a capital of £5,000 in £1 shares, to carry on the business of electricians, engineers, contractors, and manufacturers or producers and workers of and dealers in electricity, electric wires, cables, dynamo and instrument wires, &c. The subscribers are: R. R. Stell, J. A. Stell, Mrs. S. J. Stell, W. J. Stork, W. Morgan, J. H. Haley, and O. Morgan. Private company. The first directors are R. R. Stell, J. A Stell, and W J. Stork. Registered by Jordan & Sons, Ltd., 116-17. Chancery Lane, W.C.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTRIC COOKING APPLIANCES.—The latest catalogue from Simplex Conduits contains particulars of a number of forms of electric heating and cooking apparatus for domestic use, a branch of work to which the company has paid a good deal of attention of late. The kettles range from a cheap form of tinplate kitchen kettle to ornamental drawing-room tea-kettles on wrought-iron stands. Several useful patterns of water and milk heaters are included, and some attractive designs of hot-water cans, some of which are fitted with regulating switches so that they can be used either for boiling or for keeping water hot. Apparatus for the table is represented by a Russian coffee machine and a hot-water urn, hot dishes and hot plates, and a charming design of antique brass egg-boiler. Other apparatus includes glue-pots, sealing-wax heaters, sterilisers, curling tongs heaters, shaving pots, flat-irons, and saucepans.

ELECTRICAL SUPPLIES.—A very complete catalogue of electrical supplies has been brought out by Messrs. Ward and Goldstone, of Manchester, which contains particulars of a long range of articles manufactured at their large new works at Springfield Lane, Salford. The first section of the list deals with fuses and distribution-boards, and attention should be drawn to several improved patterns of replacement fuse carriers. There are also a number of ironclad fuses, some of which are combined with the firm's "Dutton" ironclad switch. Water-tight and other plain fittings for mills, factories, &c., are listed, many of them suitable for metal filament lamps, and a full line of interior conduit material is included. In the section devoted to switches, plug lamp-holders, &c., we notice a special form of cord-grip designed to protect the flexible where it leaves the lamp-holder. Prices are included of carbon and metal filament lamps and a special design of auto-transformer for enabling low voltage lamps to be used on ordinary circuits. Other items comprise fans, motor starters, porcelain insulators, and stage lighting apparatus, and long sections are devoted to cables and wires, bells and accessories, and high-class electric light fittings respectively.

ENGINEERING LITERATURE.—Messrs. Crosby Lockwood & Son send us the first number of a quarterly circular of engineering and technical literature, classified under subjects, published at their recently opened technical book-room in Victoria Street. The circular contains particulars of a number of important books on engineering, science, and technology published during the past three months in England and in America, and it will be repeated every quarter.

FLAME ARC LAMPS.—The Union Electric Co. are issuing to non-technical consumers a very attractive coloured mail card representing an "Excello" lamp surrounded by moths and butterflies, with the inscription, "It always attracts."

OUTSIDE FITTINGS.—A new leaflet from the Edison & Swan United Electric Light Co., Ltd., illustrates a series of shop window and street lamp fittings, consisting of strongly-made carriers with half-clear, half-opal reflecting globes and three light tale fittings.

PREPAYMENT METERS.—The Rochdale Electric Co., Ltd., have sent us a pamphlet describing the latest form of the Watson prepayment meter, which is of the clockwork-driven discontinuously integrating pattern of very ingenious construction. Since the original appearance of this meter some improvements in detail have been made, chiefly with a view to rendering it impossible to affect the reading by tampering with the meter. Two of these meters are on view at the Franco-British Exhibition. One is for continuous current with a capacity of 6-8 c.p. lamps for penny-in-the-slot, and the other for alternating current with a capacity of 10-8 c.p. lamps for shilling-in-the-slot. The latter meter is fitted up with 10 lamps and 10 switches for demonstrating purposes.

SWITCHGEAR AND ACCESSORIES.—Mr. P. F. Brittain, who holds the sole agency for the Universal Electric Manufacturing Co., of Peckham, is sending out an abbreviated list illustrating some of the specialities of the company. A representation of one of the sub-station switchboards which the firm have supplied to the Franco-British Exhibition is included, and particulars are given of a number of special patterns of chopper switches, bridge and switch fuses, ironclad fuse boxes and boards, battery switches, complete choking coils, street posts, brackets, and pillars, and cable sockets and boxes.

TICKET PUNCHES.—British Insulated and Helsby Cables, Ltd., have issued a leaflet descriptive of the Mallins' patent magnetically locked ticket punch, which is in extensive use on the Liverpool tramway system. The punch is provided with a removable circular cover to which a locking bolt is attached. A slight circular motion applied to the cover enables this bolt to shoot into a suitable hasp, thus effectually locking the cover to the body of the punch. The cover can now only be unlocked by the application of a specially designed and powerful electro-magnet. If any attempt is made to pick this lock a shutter descends inside the punch, and the word "caught" appears at a window provided in the cover. The number of tickets punched is accurately recorded by a reliable self-setting veeder conveniently fixed inside the case.

WATERTIGHT AMMETERS AND VOLTMETERS.—A new list has been issued by the Union Electric Co. of ammeters and voltmeters in watertight cases, constructed and tested so that they will work under actual pressure conditions. These instruments are manufactured by Messrs. Hartmann and Braun, of Frankfurt. The movements included one of the electromagnetic moving coil hot wire types, and these are contained in a large variety of designs of cases constructed of various materials, and finished in different ways, to comply with the requirements of a great variety of conditions of practical working.

Strike.—The employees of the Metropolitan Amalgamated Carriage & Wagon Co. at Wednesbury are out on strike, in protest against the dismissal of one of the workmen. They have taken advantage of the opportunity to put forward some alleged grievances, and now ask for a 10 per cent. advance of wages. The Chairman of the company declines to treat with the men until they have all returned to work, but the latter regard this as a means of shelving the difficulty until certain large contracts now in hand are completed. They have therefore decided to continue the strike. About 1,200 men are affected.

SUMMARY

CONSIDERABLE losses have been made on the undertaking of the Acton Urban District Council, who convert and distribute a supply bought in bulk from the Metropolitan Electric Supply Co. The accountant has issued a special report on the subject, in which he states that the more electricity the Council supplies the greater will be its deficiency. (Page 274.)

IN response to complaints by the municipal authorities of Ealing, Col. Yorke made another inspection of the track of the London United Tramways last week, but complaints are again being made that the inspection was insufficient, as the Borough Surveyor was unable to keep pace with Col. Yorke during his walk over the track. The Colonel broke all records by inspecting 2 miles 10 yds. of track on foot in 27 minutes. (Page 274.)

TESTS of a 5,000-6,000-kw. Willans-Siemens' turbo-alternator at Manchester, showed steam consumptions below 16 lbs. per unit, with steam at 190 lbs. with 100° F. of superheat, and a vacuum of 27 ins. (Page 274.)

A NOTABLE example of the applications of electricity in the shipbuilding industry is found in the electrical equipment of Messrs. SWAN, HUNTER & WIGHAM RICHARDSON'S shipyards. Considerable use of electric cranes is made in the large roofed-in sheds, where steamships of very large size, such as the *Mauretania*, can be built. Electric power is also used to a very large extent in driving special plate-punching machines and other appliances, about the yard, many of which were specially designed for electric driving. Electric power has been in use at the Walsend yard since 1893. (Page 275.)

WE are able to publish a full list of all the firms who have, up to the present, notified their intention of exhibiting at the Manchester Electrical Exhibition in October. (Page 279.)

THE inauguration of the public electricity supply at Arbroath, Scotland, took place yesterday. The history of the undertaking dates back to 1899, when the first Provisional Order was obtained, but no supply was obtainable until this year. The steam-driven station has at present a capacity of 450 kw., but extensions will be necessary in the near future. The supply is continuous current at 500 and 250 volts. (Page 280.)

AN article by Mr. C. C. MONCKTON gives some interesting results of the working of the Trinidad-Tobago wireless telegraph system. (Page 281.)

ONE of the Papers read before the recent Convention of the American National Electric Light Association was by Mr. P. D. WAGONER, and dealt with the use of tungsten lamps in series for street lighting. Compara-

Digitized by Google

tive tables of costs of various forms of street lighting under American conditions are given. (Page 283.)

A Paper by Mr. W. W. Freeman, read at the Chicago Convention of the American National Electric Light Association, contains an interesting review of the effect of the introduction of metal filament lamps on the electric lighting industry. (Page 284.)

An armature coil winding machine, which is in extensive use, and which obviates the necessity for separate formers for each sized coil is described. (Page 285.)

Under Electrometallurgy and Electrochemistry an abstract is given of a long Paper by E. Stassano upon the treatment of iron and steel in the electric furnace. Figures of costs are gone into, and a description is given of the author's rotary furnace, examples of which are to be found in quite a number of steel works on the Continent. (Page 286.)

Prof. Carus-Wilson has sent in an addition to his reply to the discussion of his lecture on "Rail Corrugation," delivered before the Tramways and Light Railways Association on July 10th last. In a written communication to the discussion, Mr. F. Bland calls attention to the corrugations which have appeared on the tyres of the wheels on the Helsingborg tramways, and a communication from Mr. W. F. Ireland relates to the effect of the conical surface of the tyres. (Page 287.)

Illustrations are given of some new wall plugs recently introduced, on page 288.

An elaborate system of high pressure water supply for fire protection is being laid down in New York; the mains are fed at pressures up to 300 lbs. per sq. in. by powerful centrifugal pumps, driven by 800 b.h.p. induction motors at various pumping stations. (Page 289.)

A Paper read before the National Electric Light Association, and purporting to be a general review of the progress made in the electrical industry during the year 1907, gives some interesting information relating to the state of the industry. Of particular interest are the various methods of charging for electrical energy; those in vogue in Montreal especially are worthy of attention. Miscellaneous information with regard to the progress in the lighting industry and also concerning the testing of meters, and the lighting of advertising posters, is given. (Page 289.)

A Paper by Mr. W. L. Waters, read at the recent Convention of the American Institute of Electrical Engineers at the Atlantic City, dealt with recent developments in single-phase generators, and showed how the two principal difficulties in their design of single-phase generators of large pole pitch, namely, in the results of pulsation in the armature reaction and the mechanical stresses on the end connection of the armature coils, can be overcome by the use of copper dampers and substantial supports for the end connections. (Page 291.)

A Paper by Mr. W. F. Long, read before the Cape Town section of the Institution of Electrical Engineers, contains some notes on the electric lighting of main and side streets in Cape Town by means of flame arcs and metal-filament lamps. A comparison of cost was also given between the latter and incandescent gas lighting. (Page 293.)

The patent specification of H. A. Mavor for the speed control of a polyphase induction motor, effected by arranging for the primary member to rotate in either direction, was published at the Patent Office on Thursday last. Among the other specifications published is one by R. Lenner for a limit switch for small house-lighting installations, and another by H. G. Reist for an improved method of ventilating the core bodies of electrical machinery. Siemens Brothers' Dynamo Works and J. Birrer have one relating to the construction of the rotating field systems of turbo-alternators. A specification by Dr. R. Goldschmidt describes an alternating current generator with a short-circuited rotor and neither brushes nor slip-rings, and another by G. Siebt relates to improvements in wireless telephony. Two other patent specifications abstracted refer to the manufacture of an insulating material from peat, and to flexible supports for metal filaments respectively. (Page 294.)

The works of Messrs. Ernest Scott & Mountain, near Newcastle, are chiefly devoted to the manufacture of electrical machinery for mining purposes. As will be seen from an illustrated description of the works in this issue practically the whole of the machinery is electrically driven. Power is taken from the mains of the County of Durham Electrical Power Distribution Company. (Page 295.)

Under Electrical Science in the British and American section, notes are given on recent work regarding radium emanations. In the Papers abstracted in the Continental section, Kreusler describes the magnetic and electric properties of absolutely pure iron; Reboul investigates the "electrocapillarity" of metals immersed in gases; and Mercadier announces an extension of his system of monotelephonic transmission. (Page 297.)

The new Queen's Road tramway extension in Belfast, which has been constructed by the Harbour Commissioners to facilitate access to the shipbuilding yard, was opened last week. The final surplus on the last year's working of the Belfast Corporation tramways amounted to £4,306, after a contribution of £8,962 to the General Purposes fund of the Corporation. The working expenses averaged 4·94d. per car mile.—The accounts of the Blackburn undertaking shows a net profit of £1,144, and the tramways accounts a profit of £804. The adoption of the trackless trolley system has been proposed in the suburbs of Dublin.—A conference is to be held between a number of local authorities in order to consider the present condition of the permanent way of the London United Tramways Co., which is alleged to be very unsatisfactory.—A new development has occurred in the Haslingden tramway negotiations owing to the discovery that the Parliamentary powers, although permitting the working of tramways, do not empower the construction of a generating station. The Corporation are appealing to the Board of Trade. It has been decided not to employ the Dolter system for the projected Hythe tramways.—The Portsmouth Electricity accounts record a payment of £2,000 towards the rates and £335 carried to reserve. The total cost per unit, including all capital charges and provision to reserve, was 2·64d. per unit. (Pages 299-300.)

Local Government Board inquiries have been held at Salford (£15,281) and Tonbridge (£4,200). For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. (Page 301.)

A number of tenders have been received for arc lamps at Gravesend, but owing to the amount somewhat exceeding the Engineer's estimates, a decision of the matter has been deferred. A large contract has been given by the Canadian Government for the construction of overhead lines in connection with one of the Niagara power schemes. (Page 302.)

At the meeting of the Metropolitan District Railway Co. last week, Sir George Gibb stated that the Company was now in a much sounder position than it had been. The number of passengers carried during

Digitized by Google

the period under review had increased by 16½ per cent. over the corresponding half of 1907. The net result of the half year's working was a deficiency of £8,951, as compared with the figure of £18,035 for the corresponding half of 1907. At a meeting of debenture holders of Messrs. Willans & Robinson, it was decided to sell the Company's leasehold interest in the Queensferry works. It was announced at the meeting of the Loch Leven Water & Electric Power Co. that considerable progress was being made with the scheme, and that the production of aluminium at Loch Leven would commence some months earlier than had been anticipated. (Pages 302-303.)

We publish this week a full list of the firms who have notified their intention of exhibiting at the Electrical Exhibition to be held in Manchester in October. The total number is 177, which just exceeds the numbers represented at the exhibition at Olympia in 1905. There can thus be little doubt that the success of the exhibition will be assured, as although the expenses will be far heavier this time owing to the necessity of erecting a special building for the occasion, it is but reasonable to expect that a large number of firms who are still hesitating will now decide to take part as soon as they see how many of their trade competitors are already on the list. It must also not be forgotten that the Olympia exhibition realised a handsome surplus, and that from the purely financial point of view the results depend as largely on the number of visitors attracted to the exhibition as on the number of exhibitors. From the standpoint of the exhibitors themselves, this latter consideration is the most important, quite apart from whether the exhibition itself pays its way, and the task of making the show attractive is one to which the individual exhibitor contributes as much as, if not more than, the organisers. We believe that all the firms on the list have taken up the matter whole-heartedly, and that they will spare no effort in displaying to the very best advantage all they have to interest the electrical public. Among the absentees a few of the larger electrical firms are to be noticed, and this is a matter for regret as we cannot but think that it is false economy to abstain from taking part in a representative exhibition of this nature; as we have said, there is reason to hope that at least some of these firms will change their minds. It was feared at one time that the firms of the Cable Makers' Association would abstain from exhibiting altogether, but this fear has not been realised; the British Insulated & Helsby company are on the list, and it is not improbable that more will follow suit, especially as there are several non-Association firms there. The electrical fittings makers are not present in force, but doubtless many are exhibiting through local wiring contractors and wholesale agents, several of whom have already applied for space. The same applies to a number of other manufacturers who will be represented by their district agents.

Attention of electrical engineers has been called to the deplorable balloon accident at the Franco-British Exhibition last week by the suggestion which has been freely made, that the fire was possibly of electrical origin. From the remarks made by the coroner at the opening of the inquest on Tuesday, it appears that he considers that sufficient evidence will be available to ascertain the cause of the gas having become ignited. In order to guide the jury, however, before evidence was heard—a somewhat indiscreet proceeding in this case—he told them that there was no reason to suppose that anyone had been smoking in the marquee in which the explosion occurred, and that there was no suggestion of sparks from any factory in the neighbourhood, yet, of course, it was an undoubted fact that something must have ignited the gas, and he took the jury to view the tent and its surroundings "to see the electric wires, and to learn whether there was a short circuit or sparking." The coroner also stated, however, that, so far, there seemed to be no negligence attached to anyone. The inquiry is adjourned until September 2nd, and we await the further proceedings with interest. In the meantime, we would suggest that electrical experts be employed to view what is left of the tent, &c., and of the electrical installation to settle if possible the question as to whether the cause of ignition was "electrical." This may not be difficult. It has been stated that a fan driven by an electric motor in the marquee itself was actually employed to ventilate the enclosure, and to remove any gas from it, and that the commutator of this motor was exposed. This has still to be proved by evidence, and if it is proved to be a fact we shall have to express our disagreement with the Coroner's view that there was no negligence. To employ a commutator type of motor in a tent close to a bag containing a large volume of hydrogen gas would be absolutely foolhardy.

During last week a condition of affairs occurred at Covent Garden market that is apt to recur at occasional intervals. A cold June, followed by a sufficiency of rain, and three weeks' of hot weather, from the middle of July to the first week in August, combined to produce simultaneously unusually heavy crops of vegetables, with the result that the supply far exceeded the demand, and phenomenally low prices were reached, which more than counterbalanced any advantage that the market gardeners may have obtained by the healthy output of their fields. This recalls one of the reasons why the application of electricity as a stimulant to plant growth should receive continued attention. The late Prof. Lemström pointed out that not only does the electric discharge produce a greater output per acre of land cultivated, but it has the additional effect of hastening the ripening of the crop. Mr. Newman has confirmed this in his experiments, and its commercial value is one that is of the utmost importance. In advancing by a few weeks the time at which the various vegetables are ripe for picking, their market price may be doubled or trebled, and this effect has a far greater worth to the grower than a fairly large percentage increase in the productiveness of his ground. We would refer all those who are interested in this subject to Sir Oliver Lodge's communication, published in our issue of July 16th, which calls attention to the fact that the application of electricity as an aid to agriculture has passed beyond the stage of a scientific experiment, and has reached a point where useful commercial results are obtainable. He describes

Digitized by Google

Mr. Newman's large-scale experiments carried out under practical working conditions. The installation amounts to very little more than the erection of a network of wires over the field at a height at which they will not be disturbed, and arrangements for keeping these wires continuously charged at a high electrical pressure. The pole-work, &c., is of a simple character, and, although the electrical generating machinery and its accessories are of necessity more complicated, when it is once fitted the subsequent supervision and maintenance is a comparatively small matter.

HEAVY LOSSES ON THE ELECTRICITY UNDERTAKING AT ACTON

THE position of the electricity undertaking at Acton is giving considerable concern to the Urban District Council, who have apparently been unsuccessful in their other branches of municipal trading as well. The *Times* published on Tuesday a *résumé* of the accountant's statement on the accounts, in which it is said :—"The electric light undertaking showed a loss, there being a deficiency for the year of £2,934. The total cost to the Council of each unit, exclusive of loan charges, was 3·48d., as against 3·76d. in the preceding year, and the Council is in this position that the more electricity it supplies the greater will be its deficiency; this has resulted in gas being substituted for electricity in the streets. The total debt on capital account in connection with this undertaking was £58,011."

We have applied to the Town Clerk for a copy of this report, but he has not seen his way to send us one. We have already summarised in our issue of July 23rd a previous statement issued by the accountant, and we have this before us, together with some notes upon it made by Mr. Blair, the Electrical Engineer, and a copy of the accounts themselves for the year ended March 31st last. Electrical energy is bought "in bulk" from the Metropolitan Electric Supply Co., and is converted by the Urban District Council, and retailed to consumers. It appears that the total sum arrived at by adding the cost of conversion and distribution to the amount paid for the units "in bulk" and the capital charges far exceeds the revenue from current sold. We are endeavouring to obtain some further figures, and to check some items in the accounts which are not very distinctly rendered, and hope to present our readers with an analysis in our next issue.

COL. YORKE'S INSPECTION OF THE EALING TRAMWAYS

THERE have for some time been disputes over matters connected with the tramways between Ealing Town Council and the London United Tramways Co. It will be remembered that there was considerable opposition to the Parliamentary sanction of the tramways to the district, and although ultimately this was withdrawn, the terms of settlement were not regarded as satisfactory to either party. Since 1901, when the tramways commenced running, there have been frequent complaints from the local authority with regard to the conduct of the trams, and the tramway company have been accused of laying insufficiently heavy track, upon which they are running cars of excessive weight. Not only has the noise made by the cars been objected to repeatedly, but it is alleged that these heavy cars with top covers frequently sway in such a manner as to endanger the safety of the public. Representations to the Board of Trade with regard to the unsatisfactory condition of affairs have several times been made, but it is stated that in several of these cases the tramway company have temporarily patched up the track before the arrival of the inspector. The attitude taken by the tramway company is that the track is in perfect order and that the safety of the public is in no way in danger, and they deny that temporary repairs have been made just before Board of Trade inspections.

Col. Yorke, the Chief Inspector to the Board of Trade, has recently carried out three inspections, but the Ealing authorities have complained that these examinations of the track were not sufficiently thorough. The third inspection took place last week under somewhat amusing circumstances. It appears that Col. Yorke first of all inspected the lines by driving along the road in a motor-car belonging to Sir Clifton Robinson, but not accompanied by the Corporation officials. This procedure was not approved of, and on account of a protest Col. Yorke visited Ealing again by appointment, and met the Mayor and other officials, saying that he had come to inspect the line again on account of their complaints, and was ready to go over the entire length of the track. The following amusing account of what actually occurred at this juncture is contained in the *Morning Leader* :—

"Without more ado, the gallant officer—who, though elderly, is a tall, spare, and able athlete—moved off down the track as though he were late for the last train, but would catch it or die. The surprised officials panted after the fast and long-striding colonel, but soon saw (for it was a proper August day) that they would not be in at the finish. For the Mayor of Ealing, as his interested burgesses lining the pavement soon regretfully observed, came down very soon to his first speed, and then reversed his gear. The surveyor, who has seen fifty years' municipal service, but is still hale and a good sport, though his beard is white, tried hard at first, but got off the track like his chief and waved adieu to the rapidly diminishing colonel. But he provided the officer with a time-keeper. He sent a tram after him, and somebody with a stop-watch. The colonel did the first mile in 14 minutes with ease. The full course is two miles ten yards, and getting near the end the colonel sprinted, fair heel and toe, and did the balance in 13 minutes. He was followed closely by two perspiring tramway officials. But the colonel was as fresh as when he started."

Although comparisons are made between the ages of some of the Corporation officials and Col. Yorke, it may be remarked that the hero of what has been described as an "Olympic" inspection is over sixty years of age.

When the Colonel returned by tramcar to the Town Hall and again met the authorities, they were in a great state of indignation. The surveyor again complained that the inspection was quite insufficient, but in reply Col. Yorke at once offered to go over the line again, that is to say between the Town Hall and Hanwell boundary, and, proceeding to mount a tramcar which had just stopped opposite the Town Hall, he said, "Come along, we will get into this car." The surveyor, however, refused to traverse the line with Col. Yorke in a car, although he said he was prepared to walk with him as far as was deemed necessary. Col. Yorke, however, declined to accede to this, and, after some further conversation, it is reported that the Mayor has forwarded an official protest to the Board of Trade.

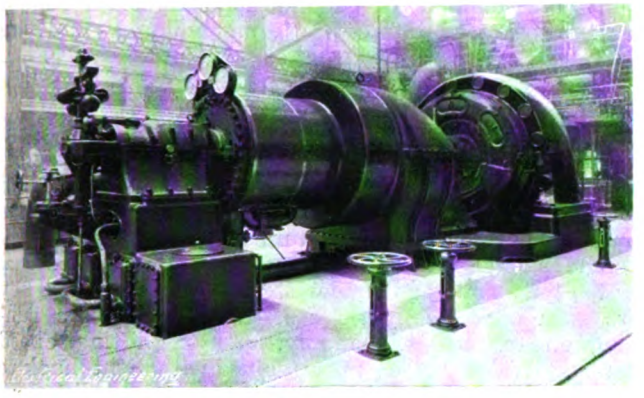
TESTS ON A 6,000 KW. WILLANS-SIEMENS TURBO-ALTERNATOR

BY the courtesy of Mr. S. L. Pearce (City Electrical Engineer, Manchester), and of Messrs. Willans & Robinson, we are able to publish some of the results of the tests of the 6,000 kw. Willans-Siemens turbo-alternator, which was put into operation at the Stuart Street works of the Manchester Corporation last May. The tests, made last June, show that the steam consumptions at full load were practically the same as the guaranteed figures, in spite of the fact that doubt had been expressed in some quarters whether the results promised would be obtained in actual practice. Owing to the machine having been originally specified for a 5,000 kw. normal load, the guarantees were at this rating and also at 25 per cent. overload. The machine was made, however, in order to run continuously at 6,000 kw. The guarantees were: at 5,000 kw. 16·03 lbs. of steam per unit generated; and at 6,250 kw. 15·85. These figures apply to steam at 190 lbs. pressure, with a superheat of 100° F., and a 27 in. vacuum. This vacuum is the highest that it will be possible to run at regularly owing to the high temperature of the cooling water. [It will be remembered that the Manchester Corporation are now making arrangements for a better water supply—ELECTRICAL ENGINEERING, Vol. III., p. 752.] The actual steam consumption was below 16 lbs. per unit at loads above 5,000 kw., the curve reaching a minimum of 15·84 at 5,650 kw.

A full description of the machine appeared in our issue of May 14th last (ELECTRICAL ENGINEERING, Vol. III., p. 735), but for convenience we repeat a few of its leading characteristics.

Digitized by Google

A general view of the set is shown in the illustration below. A feature is the comparatively small length of the machine: its overall length is only 36 ft., and the overall length of the turbine and alternator is



General View of Willans-Siemens 6,000-kw. Alternator.

46 ft. 3 in. The diameter and the high-pressure expansion chamber is 34 in., the intermediate pressure 51 in., and the low pressure 77½ in. The length of the low-pressure blading is 8 in. The diameter of the turbine shaft is 11 in., the weight of the rotor 13 tons, and the total weight of turbine and alternator 158½ tons.

The machine is totally enclosed, and air is forced into the stator at a pressure of 3 in. of water, passes through the stator and rotor, and out again through the hollow feet of the stator to an exhaust duct which leads outside the engine-room. A small house has been built outside the generating station to accommodate the motor-driven Sirocco-blower, which is capable of forcing 21,000 cub. ft. of air per minute through the alternator. Air is drawn into the fan-room through a dust-filter consisting of zigzag screens of woolly cloth mounted on a bamboo frame. The fan is driven by a 23 b.h.p. motor.

The following are the leading specified particulars with regard to the alternator:—

Output.—Normal full load output, 7,060 k.v.a. or 6,000 kw. with a power-factor of 0·85.

Generator supplies three-phase current at a pressure of 6,500 volts between phases, and a frequency of 50 cycles per second, when running at 1,000 r.p.m.

Overload.—The machine is capable of dealing with overloads of 15 per cent. continuously, 25 per cent. for 1½ to 2 hours, and 50 per cent. for ¼ hour.

Temperature Rise.—At normal load the machine is rated for a temperature rise not exceeding 45° C.

Excitation.—The generator is excited at 200 to 225 volts from the station direct-current bus-bars.

The alternator is of the salient pole type, there being six poles of round section, each pole being a separate casting. The field windings are of flat copper, insulated with presspahn between turns, and pressed together with a pressure of 100 tons. The stator of the machine consists of open slots with former-wound coils, there being four slots per pole per phase. The condenser is placed immediately beneath the turbine. It is of the "Contraflo" type, with a cooling surface of 10,500 sq. ft. Its air-pump is driven by a 50 h.p. motor, and the circulating pump by a 250 h.p. motor.

THE APPLICATION OF ELECTRICITY TO A GREAT SHIPBUILDING INDUSTRY

Electrical Equipment of Messrs. Swan Hunter & Wigham Richardson's Shipyards

THE name of Messrs. Swan Hunter & Wigham Richardson, Ltd., has been prominent in the mind of the technical public ever since the great engineering triumph of the construction and launch of the *Mauretania* was accomplished, although previously to this the history of the firm represents a no mean series of pioneering successes. From the first this firm, or combination of firms, adopted their own methods of tackling shipbuilding problems, with the result that their yards are probably the finest in that centre of shipbuilding industry, the Tyne, and enable them to turn out the largest boats now afloat in remarkably short time. The equipment of these yards affords a remarkable example of the applications of electric power to shipbuilding, and by the courtesy of the firm we are able, in the following article, to present a few notes on the electrical plant installed and the method of supply.

It should be said at once that electricity was adopted for lighting at the Wallsend yard as long ago as 1882, and for power in 1893. To understand the system adopted in the yards, it must be remembered that the operations of the Newcastle-upon-Tyne Electric Supply Co., Ltd., have, within recent years, developed from the generation and distribution of electricity through a comparatively restricted area to a system of power supply in bulk over the major portion of the two counties. For the first few years of supply a 240-volt direct-current system was sufficient and the earlier portion of Messrs. Swan Hunter's shipyards and lighting are fed from this source. Lately, however, a three-phase supply has been obtained, being transformed down from a pressure of 6,000 volts to 440 volts, and circuits carrying about 400 amperes each have operated motors for various purposes running at a frequency of 40 cycles per minute. The whole of the shipyard machinery, with one or two unimportant exceptions, is electrically driven, over 5,000 h.p. of motors and lighting being installed. For the purpose of supply three sub-stations are in operation, one being situated at the Neptune Works, Walker (the first yard supplied from outside mains), another near the Dry Dock Department, and a third at Wallsend. The two former are interconnected on the distribution side, and it is possible that this system of linking may be extended. As an example of the fluctuating nature of the load, it may be mentioned that the starting, stopping, or reversing of a single plate roll means an average instantaneous alteration of load of 50 h.p.

The main purposes for which the supply is used are for operating the various machines in the joiners' workshops and the engine shops, direct driving many of the shipyard tools, driving hydraulic pumps and air-compressors, operating overhead cranes in the engine works and shipyard, driving the service pumps for drawing water from the river for yard purposes and into the testing tanks, lighting the yards with arcs and the offices with incandescents, and operating a recently-installed dry-dock pumping equipment. Roughly speaking, direct current is used for these purposes, with the exception of the joiners' machines, the yard water service pumps, the dry-dock pumps, the overhead cranes in the new Neptune shipyard, and a large air-compressor recently installed in the Wallsend sub-station. In addition, when a boat is being equipped a direct-current 240-volt service is taken on board the

Digitized by Google

vessel, from which portable electric drills, deck planers, and temporary shop lighting are operated. A direct-current voltage of 480 is only used in the case of the overhead cranes in the engine works, the remaining direct-current motors being 240 volts compound-wound giving variable speed by shunt regulation; while in the oldest sheds some cranes erected in 1892, and which were operated by steam-driven generator sets, are still worked by two of the old Clarke-Chapman generators, running at 110 volts and direct coupled, one at each end of the shaft of a 150 h.p. three-phase motor. As this service was only remodelled four years ago, full credit must be given to these pioneer machines for thirteen years' good service, as the only alteration made electrically was to substitute a compound winding for the separately excited shunt winding, to further fit them for crane service.

The cable system throughout the yards is nearly all an overhead protected or insulated wire distribution, partly of bare copper but mostly either on wooden poles or insulators, so far as outdoor work is concerned, as the wires are likely to be fouled by constructional iron-work on the jibs of the locomotive cranes used throughout the yards. In the shops the cables are rubber covered and mounted on porcelain insulators. Where it is necessary to use underground cables, these are laid solid in bitumen.

The largest and most modern sub-station is that situated at the east end of the Wallsend yard, inasmuch as in addition to the 240-volt direct-current supply it contains a high-tension chamber separated off from the rest of the building by expanded metal partitions and containing six oil-cooled Berry transformers, each of 200 kw. capacity, connected in star on their primaries and in mesh on the secondaries so as to form two sets of converting systems from 6,000 to 440 volts. In order to supply the pneumatic system in this part of the shipyard, an Alley & McLellan air compressor, capable of giving 1,200 cubic feet of air per minute at a pressure of 90 to 120 lb. per square inch, is direct coupled to a 260 h.p. three-phase slow-speed B.T.-H. motor running at 170 revolutions per minute, and, in addition, there are two 250 kw. B.T.-H. motor-generators for supplying the direct-current energy. The switchboard is provided with duplicate bus-bars, and means are provided for placing any circuit or any machine on either of them. If required, the whole lighting and power output of the station can be united by combining the bus-bars.

The roofed-in sheds in which the *Mauretania* was built are familiar in general appearance to all our readers who are interested in shipbuilding, and are partially illustrated in Fig. 1, showing prominently one of the overhead cranes, and incidentally showing the *Mauretania* in course of construction. These sheds are in duplicate, 680 feet long and 110 feet high from ground to crane-rails, and 90 and 100 feet wide respectively. Their overhead electrical equipment consists of four cranes capable of lifting 5 tons normal load single purchase, and 10 tons maximum with double purchase, and four smaller ones capable of lifting 3 tons normal and 6 tons maximum under similar conditions. They are each operated by three series-wound motors running on the 240-volt supply, and the lifting speed varies between 140 feet per minute with light hook to 70 feet per minute with full load. The controllers are

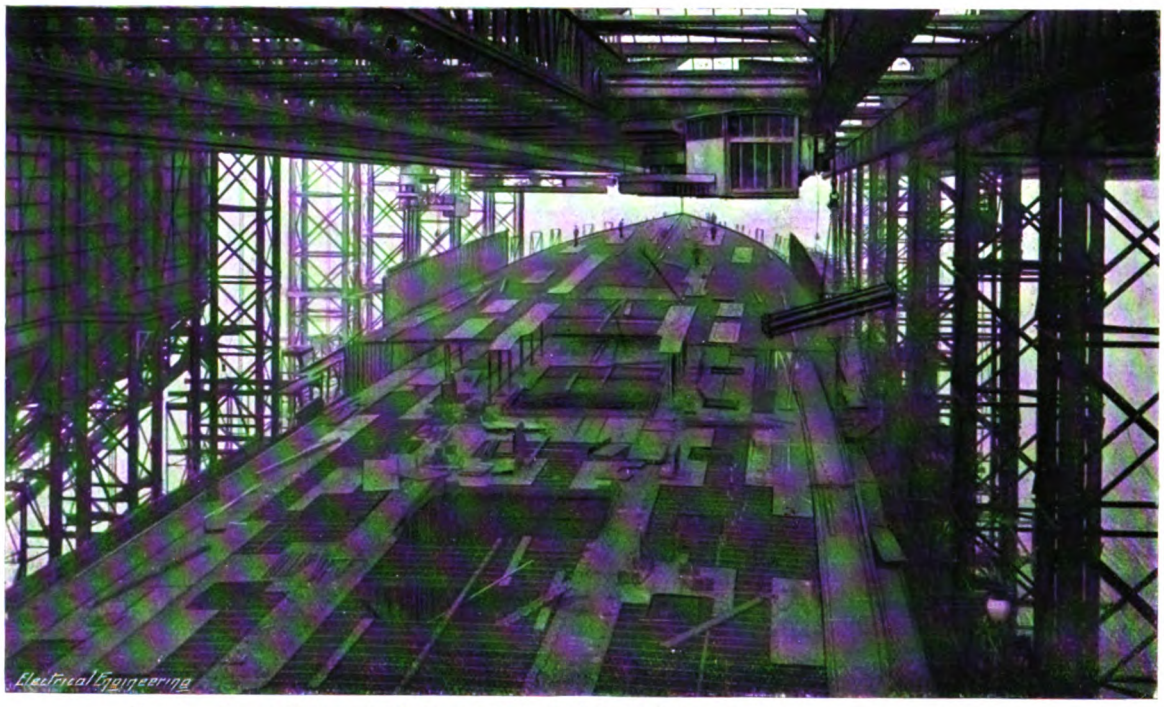


Fig. 1.—Large Roofed-in Shed showing R.M.S. "Mauretania" in course of Construction.

placed in a cage containing the driver, suspended beneath the running rails near the end of the revolving jib, so that the driver has an almost uninterrupted vertical view of his work. The cranes can be transported from one set of rails to another by means of a large transporter running across the end of the sheds, and their normal position when a shed is working full is to have three small cranes, one at each side and one on the centre set of rails, with two of the larger cranes running on the intermediate tracks. Five cranes can therefore be working at various parts of a vessel at one time. At the Neptune works a new set of sheds, 400 feet long, has been erected which are not roofed in, and in this case two cantilever cranes for the outside berths and two inner cranes are employed. These are each capable of lifting three tons. They are operated by means of three-phase current slip-ring motors, the rotor resistances being sufficiently large to carry their full current continuously in order to give variation in lifting speeds. The lift of about 80 feet is accomplished at about 70 feet per minute with light hook, and a slip of about 11 per cent. being found with full load.

The heavy duty required from the plate punching,

Digitized by Google

bending, shearing, straightening, and joggling machines in a large shipyard renders independent electrical drive almost without exception necessary, and we illustrate one or two typical machines installed at Messrs. Swan

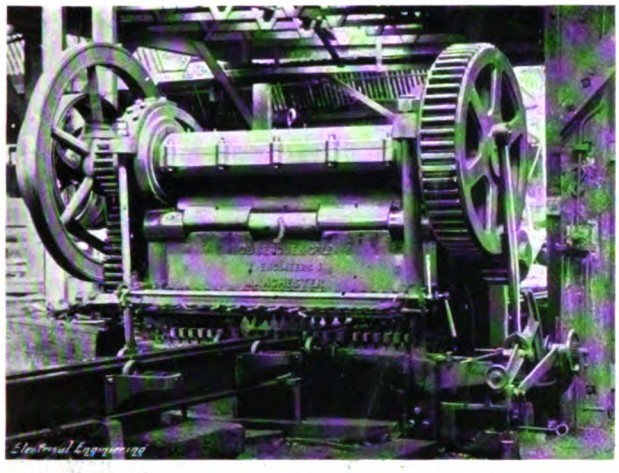

Fig. 2.—Electrically-driven Multiple Plate-Punching Machine.

Hunter & Wigham Richardson's shipyards. The first (Fig. 2) is a massive De Bergue multiple plate-punching machine capable of dealing with plates 7 feet wide and up to 45 feet long. Unfortunately, owing to the comparative insignificance in size of the motor as compared with the machine, the former is lost to view, but is located at ground-level at the side of the main upright of the machine to the left of the picture, being geared to the punch through a double set of spur-gearing. The number of punches on the machine is twenty-eight; it is designed to punch 1-inch holes through plates $\frac{7}{8}$-inch thick when cold, but the h.p. of the motor is only 20. The punches are arranged in four sets, and an interlocked controller is arranged so that not more than one set of punches operates at once. Moreover, in order to obtain graduation of power required, each set has three different lengths of punches, so that they do not all come into operation on the iron at the same time. We also illustrate a machine for countersinking the holes in plates (Fig. 3), in which the arrangement of the motor drive into a long shaft having a keyway into which fits a sliding bevel wheel for transmitting the powers to all positions will be noticed, and an electrically-driven plate-punching machine. The method of drive shown here is adopted by this firm for all forms of tools of this class. The motor is direct-coupled to the driving spindle of the mechanism, the shock of intermittent work being largely taken up by a heavy flywheel revolving in conjunction with the compound-wound motor (Fig. 4). Another interesting machine in the yard, not illustrated, is a set of plate-bending rolls by Messrs. J. Bennie & Sons, of Glasgow, capable of bending plates up to 2 inches thick and 36 feet long to a minimum radius of 2 feet, and operated by a 60 h.p. motor. In these yards hydraulic rivetters and pneumatic caulking tools are extensively used. The former are operated at a pressure of 900 lb. per square inch from three-throw hydraulic pumps operated through gearing by 40 h.p. Silvertown motors.

For the service of the boiler-shop an air-and-water pumping plant is installed, consisting of two sets of three-throw hydraulic pumps each operated by a 60 h.p. three-phase motor. These, together with the 40 h.p. motors referred to above, are automatically started and stopped from the accumulator by means of a hydraulic cylinder operating on a rack and wheel attachment on the controller. There is also an auxiliary hydraulic pump of 30 h.p. The compressed air supply is taken care of by a 60 h.p. three-phase two-speed motor having an automatically operated starter and controller.

One of the newest and most interesting portions of the equipment is an excellent dock-pumping installa-

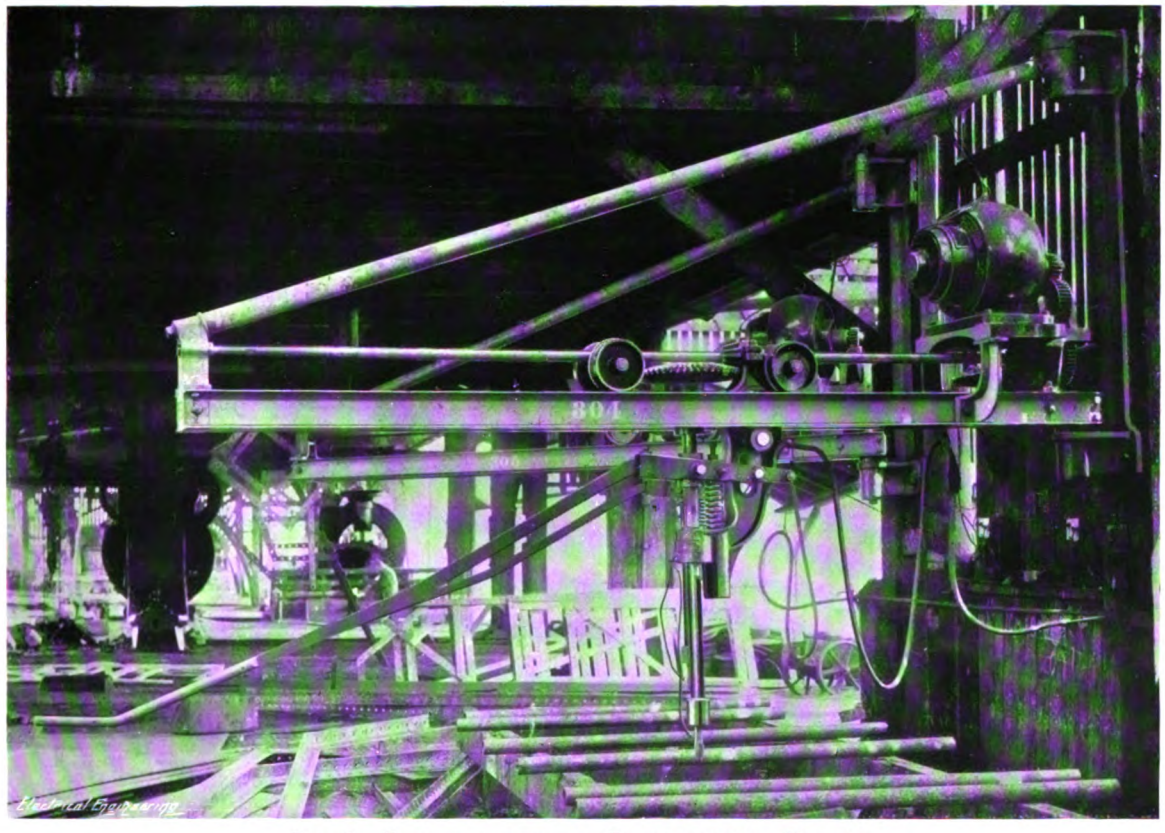

Fig. 3.—Electrically-driven Countersinking Machine.

Digitized by Google

tion which has just replaced a steam equipment for emptying a dry dock 550 feet long by 74 feet wide, and being filled at spring tide to a maximum height of 26 feet 6 inches over sill. The pump-house is below ground, measuring 56 feet by 27 feet by 20 feet. It contains all the hydraulic arrangements, but not the two main motors, these being of the B.T.-H. three-phase vertical-wound rotor induction type, and housed in a superstructure on the quayside. The motors, which are of 220 h.p. each, running at a speed of 386 r.p.m., are direct-coupled through vertical shafts to Worthington centrifugal pumps, having a 36-inch delivery each and capable of emptying the dock in 2½ hours maximum time. No regulation is found to be necessary to avoid an overload on the motors at times of approximately equal heights of water inside the dock and in the river, the pumps being perfectly self-regulating. The outlets of the pumps are, however, fitted with sluice valves, which for ease in handling

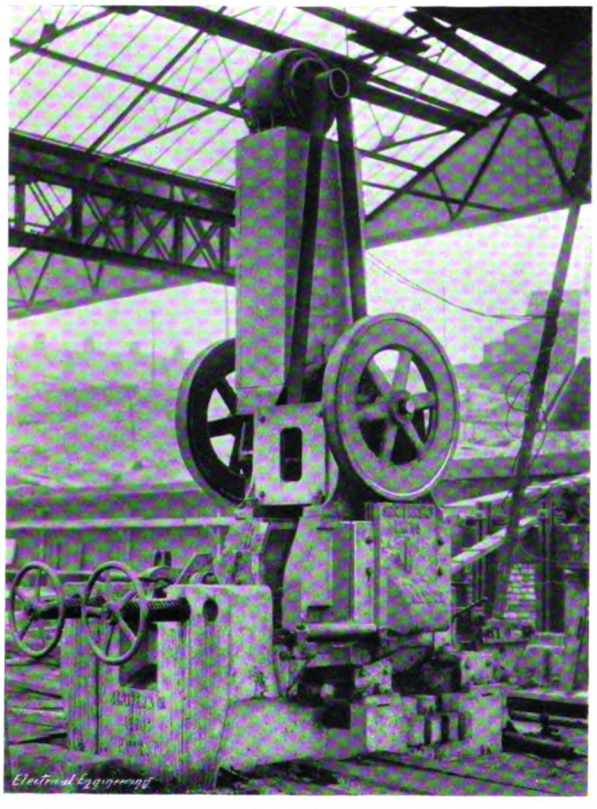

Fig. 4.—Electrically-driven Plate-Punching Machine.

are operated hydraulically. For this purpose a 15 h.p. induction motor operates the hydraulic pump, and pressure is applied either on the top of or under a piston on the sluice-valve spindle by valves situated in the pump-house switch gallery. In order to keep the dock dry against leakage after it has been pumped out by the main sets, a drainage pump with 8-inch delivery pipe is installed, direct driven by a 46 h.p. induction motor running at 480 r.p.m. This set is also used for pumping water into steamer tanks such as those of oil-tank boats when these have to be tested. In order to induce this pumping set to start work again after losing its water, as may frequently occur, a small Reavell four-cylinder air pump, giving 20-inch vacuum, driven by a 3 B.H.P. motor, is employed to suck the water through the pump when necessary. The whole of the switchgear for these motors is situated on a switch gallery at one side of the pump-house at a height rather above the spring-tide level in the dock outside, in order that under no conditions can it be flooded. The main motors are each controlled by a three-phase B.T.-H. oil break switch and a tramway type controller for inserting starting resistance, while the leakage pump is fitted with a standard B.T.-H. starting compensator. This plant has ousted two marine-type boilers and two steam-driven pumps of like capacity. The end of the dock is protected by a floatable caisson, and the pumping arrangements for this are at present steam driven. It is intended, however, to change these over in favour of electricity in the near future.

Messrs. Swan Hunter & Wigham Richardson keep an electrical shop for carrying out all works repairs, such as rewinding stators and rotors, and also for installation work on board the ships they build. An instance of the ingenuity of the department was shown when the electrical equipment of an enormous floating crane (which recently lifted the *Turbinia* bodily out of the water and deposited it in dry dock) came to be considered. A 60-volt generator was required on board for running arc lamps for night working. One of the old 110-volt dynamos from the early equipment of the works was taken; the field coils were connected in parallel, its armature kept as before, and coupled direct to a small steam engine running at 400 r.p.m. It is now running as well as ever under its new duty. Another instance is a home-made "conduit" arrangement used as an alternative to the overhead double trolley collector usually employed for the locomotive jib cranes which carry the huge plates to and from the plate-racks for storage. Owing to the increased height and outreach of the newer cranes it was found impossible to adopt the overhead system, and a device consisting of porcelain insulators with grooved tops in which the bare wire conductors rest was made. The trolley picks up the wires from these supports as it passes, running free of the insulators. Protection from contact by people passing is afforded by inclined boards, forming a species of slot system.

In conclusion, we must express our acknowledgment to the management and staff of Messrs. Swan Hunter & Wigham Richardson, Ltd., for their courtesy in placing sources of information at our disposal and giving us facilities for viewing their extensive yards.

Another Exhibition.—We have received notice of an exhibition which it is proposed to hold in October at Olympia, under the name of the Ideal Home Exhibition. Sections are to be devoted to electric and other forms of lighting, as well as cooking and heating. As the date clashes with that of the Manchester Electrical Exhibition, and also in view of the fact that a number of electrical firms are exhibiting at the Franco-British Exhibition, it is hardly to be expected that the electrical industry will be well represented.

Blankenese-Ohlsdorf. Single-phase Railway.—According to the *Elektrotechnische Zeitschrift*, some trouble has been experienced in the working of this railway. It is stated that the difficulties are due to imperfections in the constructional details of the electrical equipment, in particular of the insulation of the high-tension conductors, and not to any shortcomings of the single-phase system. The service is being dealt with at present by both steam and electric trains, and, of course, is not so good as when only electric trains were in use. The work on the cables and overhead conductors is being carried out at night, and it is expected that complete electrical working will be resumed on October 1st of this year.

Wireless Telephony.—According to the daily papers, some French naval engineers have been attempting to establish wireless telephonic communication between Paris and Dieppe, a distance of ninety miles. It is stated that several set phrases spoken into the transmitter at Paris were distinctly audible in the receiver at Dieppe. Details of the system employed are not given.

The *Matin* states that a wireless telephonic message was received fairly clearly at the Eiffel Tower station from a station at Pointe du Raz in Finisterre, some 500 kilometres from Paris. From Rome comes the news that successful experiments have been carried out by Prof. Majorana at Monte Mario, speech being transmitted distinctly at a distance of 60 kilometres.

THE MANCHESTER EXHIBITION: LIST OF EXHIBITORS

THE following is a complete list of all the firms who have notified their intention, up to the present, of exhibiting at the Manchester Electrical Exhibition in October:—

Adam's Manufacturing Co., Ltd., 106 New Bond Street, W.
Aërators, Ltd., Prana Sparklet Works, Upper Edmonton, N.
Aëro Automatic Fire Alarm Co., 66 Cheapside, E.C.
Clement Allen, 36 Wilmslow Road, Rusholme, Manchester.
Arcalia Electrical Manufacturing Co., 504 Stockport Road, Longsight.
Aron Electricity Meter, Ltd., 80A Salusbury Road, Kilburn, N.W.
H. Ashton, 8-10 Bull's Head Yard, Manchester.

Babcock & Wilcox, Ltd., 14 Deansgate, Manchester.
W. H. Bailey & Co., Ltd., Albion Works, Salford, Manchester.
W. J. Bates & Co., Victoria Iron Works, Denton, Manchester.
W. Batty & Sons, Ltd., 7-9 Market Street, Manchester.
Beanland Perkin & Co., School Close Works, Leeds.
Berry, Skinner & Co., 78 Upper Thames Street, E.C.
R. W. Blackwell & Co., Ltd., 14 Gt. Smith Street, S.W.
G. M. Boddy & Co., Newington Works, Liverpool.
G. Brady & Co., 49 Pott Street, Ancoats, Manchester.
Bray, Markham & Reiss, Ltd., Canada Chambers, Spring Gardens, Manchester.
British Insulated & Helsby Cables, Ltd., Prescot, Lancs.
British Westinghouse Electric & Manufacturing Co., Ltd., Trafford Park, Manchester.
T. W. Broadbent, Ltd., East Parade, Huddersfield.
Browett, Lindley & Co., Ltd., Patricroft, Manchester.
F. W. Brown & Co., 3 Cross Street, Manchester.
Brown, Boveri & Co., Ltd., Caxton House, Westminster, S.W.
Bruce, Peebles & Co., Ltd., Basildon House, Moorgate Street, E.C.
Bullers, Ltd., 6 Laurence Pountney Hill, Cannon Street, E.C.
Bullough's Adjustable Rail Joint Support Co., Ltd., Central Buildings, John Street, North, Liverpool.

Calmon Asbestos & Rubber Works, Ltd. (& Check Fire Door Co.), 1-3 Trinity Place, Tower Hill, E.C.
Le Carbone, 17 Water Lane, Gt. Tower Street, E.C.
Chamberlain & Hookham, Ltd., Solar Works, Birmingham.
Chorlton & Knowles, Mayfield Press, Boardman Street, Manchester.
Chas. Churchill & Co., Ltd., 6 Oxford Street, Manchester.
Climax Fire Extinguisher Co., 11 Exchange Buildings, St. Mary's Gate, Manchester.
Clipper Belt Hook Co., 251 Deansgate, Manchester.
J. Collier & Co., Warwick House, 29 King's Street, W., Manchester.
Concordia Electric Wire Co., Ltd., 64 Salusbury Road, Kilburn, N.W.
Congdon & Muir, 42 Deansgate, Manchester.
Consolidated Pneumatic Tool Co., Ltd., Palace Chambers, Bridge Street, S.W.
Crossley Bros., Ltd., Openshaw, Manchester.
Crypto Electrical Co., 155-157 Bermondsey Street, S.E.
Cunliffe & Croom, Ltd., Broughton Iron Works, Manchester.
Cutler, Wardle & Co., Ltd., 35-37 Dickinson Street, St. Peter's Square, Manchester.

T. H. & J. Daniel, Ltd., 22 Henrietta Street, E.C.
Dey Time Registers, 100B Queen Victoria Street, E.C.
Diesel Engine Co., Ltd., 179 Queen Victoria Street, E.C.
D.P. Battery Co., Ltd., Lumford Mills, Bakewell, Derby.
Drake & Gorham, Ltd., 66 Victoria Street, S.W.
Dryden & Co., Grimshaw Street Foundry, Preston.
John Dugdill & Co., Failsworth, near Manchester.
D. N. Dunlop, Westinghouse Co.'s Publishing Department, Westinghouse Works, Trafford Park, Manchester.

Electrical Engineering, 203-6 Temple Chambers, E.C.
Electrician, 1-3 Salisbury Court, E.C.
Engineer, 33 Norfolk Street, Strand, W.C.
Electrical Review, 4 Ludgate Hill, E.C.
Electrical Engineer, 139-140 Salisbury Court, Fleet Street, E.C.
Electrical Times, 8 Bream's Buildings, Chancery Lane, E.C.
Electrical Magazine, Bazaar Buildings, Drury Lane, W.C.
Electrical Field, 30-31 St. Swithin's Lane, E.C.
Electric Journal, 17 Bouverie Street, E.C.
Ebonestos Manufacturing Co., 127 Pomeroy Street, Old Kent Road, S.E.
Eckstein, Heap & Co., Waverley Mills, St. Simon's Street, Salford.
Edison & Swan United Electric Light Co., Ltd., 36-37 Queen Street, E.C.
Electric & Ordnance Accessories Co., Ltd., Cheston Road, Aston, Birmingham.
Electrical Power Storage Co., Ltd., 4 Great Winchester Street, E.C.
Electrical Press, Ltd., 37-8 Strand, W.C.
Electromotors, Ltd., Openshaw, Manchester.
Elliott Bros., Century Works, Lewisham, S.E.
Emmott & Co., Ltd., 65 King Street, Manchester.
F. Ernst & Co., 31 New Bailey Street, Manchester.
E. M. Evans & Sons, 18A-18B Fountain Street, Manchester.
Evershed & Vignoles, Ltd., Acton Lane Works, Chiswick, W.

Falk, Stadelmann & Co., Ltd., 83-87 Farringdon Road, E.C.
John Faulkner, 13 Strangeways, Manchester.
Ferranti, Ltd., Hollinwood, Lancs.

Galloways, Ltd., Knott Hill Iron Works, Manchester.
General Electric Co., Ltd., 67-71 Queen Victoria Street, E.C.
Gilbert Arc Lamp Co., Ltd., Chingford, Essex.
Glyco Metal Co., Ltd., 8-9 South Parade, Manchester.
Goodalls, Weaste, Manchester.
E. Green & Sons, Ltd., 2 Exchange Street, Manchester.
J. & H. Grevener, Eldon Street House, E.C.

Hacking & Co., Lord Street, Bury.
J. Halcrow (Nuremberg Engine Co.), 18 Coleman Street, E.C.
J. P. Hall & Co., Blackriding Ironworks, Werneth, Oldham.
G. Harland, Bowden & Co., 196 Deansgate, Manchester.
Hart Accumulator Co., Ltd., Marshgate Lane, Stratford, E.
Heatley & Gresham, Ltd., 110 Cannon Street, E.C.
Hebblewaite Bros., Ltd., Huddersfield.
Alf. Herbert, Ltd., Machine Tool Makers, Coventry.
Jas. Hodgkinson (Salford), Ltd., Ford Lane Works, Broad Street, Pendleton, Manchester.
Hoffman Manufacturing Co., Ltd., Chelmsford.
J. Hopkinson & Co., Ltd., Britannia Works, Huddersfield.
Howard Asphalt Troughing Co., Ltd., Trafford Park, Manchester.
J. Howden & Co., 105 Scotland Street, Glasgow.
W. R. Howell & Co., 42 Theobalds Road, W.C.

International Electric Co., 55 Redcross Street, E.C.
International Time Recording Co., 151-5 City Road, E.C.

J. Lomax Kendal & Co., Ltd., 4 John Dalton Street, Manchester.
Kennedy Bending Machine Co., 34 Norfolk Street, Strand, W.C.
Geo. Kent, Ltd., 199 High Holborn, W.C. (In charge of J. Pythia, Throstles Nest House, Congleton.)
Alex. Kenyon & Co., Victoria Bridge, Manchester.
J. Kerr & Co., 62 King Street, Manchester.
Key Engineering Co., Ltd., 38 Deansgate, Manchester.
Kirkpatrick & Rastall, 16 Barrack Street, Hulme, Manchester.

Lancashire Dynamo Co., Ltd., Trafford Park, Manchester.
Lancashire Electric Power Co., 196 Deansgate, Manchester.
J. E. Lea, 28 Deansgate, Manchester.
Liverpool Electric Cable Co., Ltd., 292A Vauxhall Road, Liverpool.
Ludw. Loewe & Co., Ltd., 30 Farringdon Road, E.C.
Luke & Spencer, Ltd., Broadheath, Manchester.
Lyle Trading & Manufacturing Co., Ltd., Temple Bar House, Fleet Street, E.C.

R. W. McDermott, Old Street, Ashton-under-Lyne.
Manchester Corporation, Electrical Department, Town Hall.
Percival Marshall & Co., 26-9 Poppin's Court, Fleet Street, E.C.
B. & S. Massey Steam Hammer Works, Openshaw, Manchester.
Matthews & Yates, Cyclone Works, Swinton, Manchester.
Mayer & Schmidt, Offenbach on Main, Germany.
Mirrlees, Bickerton & Day, Ltd., Scotland Street, Glasgow.
Mirrlees, Watson & Co., Ltd., Hazel Grove, near Stockport.
Mitcham Electric Fan Co., Ltd., 6 Broad Street Place, E.C.
Morgan Crucible Co., Ltd., Battersea Works, S.W.
Morton & Co., 8-9 The Arcade, Lord Street, Liverpool.
J. Musgrave & Sons, Ltd., Globe Iron Works, Bolton.

Nalder Bros. & Thompson, Ltd., 34 Queen Street, E.C.
National Gas Engine Co., Ltd., Wellington Works, Ashton-under-Lyne.
National Telephone Co., Ltd., 102 Portland Street, Manchester.
New Gutta Percha Co., Ltd., Dashwood House, New Broad Street, E.C.

O'Brien & Co., 5 Brazennose Street, Manchester.
Oliver Arc Lamp, Ltd., Cambridge Place, Burrage Road, Woolwich, S.E.
Oliver Machinery Co., Ltd., 201-3 Deansgate, Manchester.

Parmiter, Hope & Sugden, Hulme Electrical Works, Manchester.
C. A. Parsons & Co., 65-7 Prudential Buildings, Park Row, Leeds.
F. Pearn & Co., Ltd., West Gorton, Manchester.
Pearson & Co., 51 Moseley Street, Manchester.

ARBROATH ELECTRIC LIGHT AND POWER SUPPLY

THE public supply of electricity in Arbroath was officially inaugurated yesterday by the ceremony of opening the new electricity works. The resident population of this rising town, which is situated on the north-east coast of Scotland, some 17 miles distant from Dundee, is about 23,000; and, as there are several factories on the outskirts of the town, a public electricity supply was much to be desired.

As long ago as 1899 a Provisional Order for Electric Lighting was granted to the Corporation, and schemes for a small generating station were prepared. These schemes, however, were not proceeded with, and the question was not revived until 1904, when an agreement was entered into with the Empire Electric Light & Power Co. for the transference of the Order. Owing to the failure of that company, however, the Order was revoked by the Board of Trade in the following year.

A few years after this, Mr. G. Balfour, now chairman of the Arbroath Electric Light & Power Company, Ltd., made an offer to the Corporation to obtain a new Order. An agreement was concluded, and the Order was obtained at the end of July, 1907. Although two years were allowed for the commencement of the work, it is now only one year since the Order was confirmed, and the works are busily employed. It is interesting to note that the capacity of the present station is three times that of the station contemplated by the Corporation in their previous scheme. Moreover, there is sufficient space on the site to more than double the capacity of the station; and, as there is every reason to expect that extensions will soon be necessary, one end of both the engine and boiler rooms is temporary, and is constructed of corrugated iron sheeting on a steel framework.

The works are situated close to the harbour, and adjoin the dock branch of the Caledonian Railway. A siding will ultimately be constructed. The building is of brick; the engine-room measures 45 feet by 35 feet, and the boiler-room 50 feet by 45 feet. There are also a battery room and a pump room. A building which already existed on the site was found to be quite suitable for use as offices. The engine room is built in bays with brick piers supporting a gantry running the full length of the room, and carrying a 10-ton travelling crane. The brick chimney shaft which has a total height of 125 feet, is lined up to 47 feet above the ground level, and has an inside diameter of 5 feet 6 inches. The chimney was built by the Alphons Custodis Co., of London. The flues have been arranged, and space has been left for the construction of an economiser when required. The boiler plant consists of two Babcock & Wilcox water tube boilers, each capable of evaporating 7,500 lbs. of water per hour, and producing steam at a pressure of 160 lbs. per sq. in., and superheated to 480° F. Both boilers are fitted with chain-grate stokers, and the usual mountings, including duplicate feed valves. The steam piping is arranged above the boilers, and is all of mild steel with wrought flanges. Both exhaust and circulating pipes are of cast iron. Circulating water is obtained from the Brothock Burn, a river adjacent to the works.

There are two steam feed-pumps; a main pump supplied by Messrs. J. G. Weir, of Glasgow, and an auxiliary pump, horizontal duplex pump, manufactured by the Worthington Pump Engineering Co. Each of these pumps has a capacity of 1,800 gallons per hour. The feed water is treated by a purifying plant supplied by the Paterson Engineering Co., and the pump exhaust is utilised to heat the supply. A hotwell tank of 1,000 gallons capacity is also provided.

The principal generating set consists of a 300 kw. 500-volt continuous-current dynamo coupled to a triple expansion vertical reciprocating engine running at 375 r.p.m. The second set is a 150 kw. continuous-current dynamo direct-coupled to a compound engine running at 435 r.p.m. The dynamos, which are compound-wound, and are fitted with commutating poles, were supplied by Messrs. Thomas Parker, Ltd., of Wolverhampton. The engines were supplied by Messrs. Belliss & Morcom. These sets can generate at from 480 to 560 volts, and can withstand 20 per cent. overload for two hours. Messrs. Thomas Parker, Ltd., also supplied the two-machine 15 kw. balancer, a 28 kw. reversible booster, and a Tilney regulator.

Digitized by Google

The battery consists of 260 cells of the Electrical Power Storage Company's make, with lead-lined boxes, and arranged in two tiers. The total capacity of the battery is 600 ampere hours, and it is capable of delivering 400 amperes for one hour. The switchgear, instruments, and meters are carried on a white marble switchboard supplied by the British Thomson-Houston Co. Circuit-breakers are provided in each pole of the machines, and there are two sets of bus-bars with selective switches, by means of which a supply can be given at either 500 or 250 volts if necessary.

The cable network consists of Callander cables, laid solid except for a short length of cable over Brothock Bridge, which was drawn through a conduit built into the bridge during the recent reconstruction. There are three concentric feeder cables, the largest of which runs out to the factory district, and is intended to deal with the power load. This is of 0·6 + 0·6 + 0·1 sq. in. section, and is 720 yards long. Two other feeders of 0·25 and 0·15 sq. in. section respectively make up the total length of feeder cable to 1,600 yards. There is also 1,600 yards of three-core pilot cable. The distribution network is chiefly made up of three single cables of 0·1, 0·1, and 0·05 sq. in. section respectively, but there is a 0·6 sq. in. distributor in the power district. A special 0·22 sq. in. distributor supplies the arc lamps in the main thoroughfares. There are about 6,000 yards of three cable distributors.

The main streets are lit by 20 Crompton Blondel flame arc lamps of about 1,500 c.p. each. These are supported on ornamental cast iron pillars. Two 50 candle-power Osram lamps are fixed to each pillar for use when the arc lamps are extinguished. The lamps are controlled from switchboxes in the bases of the columns.

The supply has been well taken up by the residents and some of the factories, and there is every reason to expect that the undertaking will be well supported.

The contractors for the works, equipment, underground mains, and the public arc lamps were Messrs. J. G. White & Co., Ltd., and all the work was carried out in accordance with the plans and specifications of Messrs. Hawtayne & Zeden, the consulting engineers, to whom we are indebted for particulars.

THE WIRELESS TELEGRAPH SYSTEM BETWEEN TRINIDAD AND TOBAGO

By C. C. Monckton (Electrical Adviser to the Government of Trinidad)

COMMUNICATION between the islands of Trinidad and Tobago by means of radio-telegraphy has been open to the public since January, 1906, and some instructive results have been obtained from observation of the working of the system. The station at Trinidad is situated adjoining the North Post outlook for signalling incoming vessels to Port of Spain harbour; it is about 650 feet above sea-level, and a telephone line connects it to the exchange of the Commercial Telephone Company at Port of Spain, about seven miles distant. A line from this exchange is taken to a room in the Public Works Office, from which messages are sent and received.

The station at Tobago is on a hill 450 feet high, 58 miles from North Post, and about half a mile from the capital, Scarborough. On three sides of the aërial are the ruins of an old French fort, and one of these ruins has been utilised for the radio-telegraph apparatus. A telephone line runs to a small Government exchange in Scarborough.

At each station the apparatus is the same; the original transmitting sets installed consist of 3 b.h.p. Petter oil engines, driving 1½ kw. Lodge-Muirhead alternators, the current being raised to a high pressure by transformers made by the same firm.

During the first year duplicate sending apparatus was installed at each station, consisting of a 1¼ b.h.p. Petter oil engine driving a Newton dynamo used for charging a battery of ten chloride accumulators, from which power is taken when required to a Sullivan induction coil.

This last-named plant is now always employed except once a month, and it has been found suitable to communicate with a ship 200 miles distant. For longer distances the more powerful plant is used.

The accumulators are charged once a week, and the apparatus is always ready for signalling. The only trouble experienced with this smaller plant has been with the accumulators, the specific gravity gradually falling. The writer found on his last visit to the Colony that this was due to absorption of moisture by the acid of the accumulators due to the extremely humid atmosphere. The cause being found, the remedy was simple: during the rainy season liquid has to be syphoned off every few weeks, and acid added to the cells. The chlorine from the sea atmosphere has not at present affected the cells, which, during the year and a half of working, have shown no signs of deterioration.

The oscillators consist of "carpet" aërials of about 5,000 sq. ft., placed at a mean height of 65 feet from the ground. With the high-power apparatus two ¼-inch sparks in series are used, whilst for ordinary routine work with the induction coil a single ¼-inch spark is generally employed. The induction coil is rated for 10 amperes, but generally about 3 amperes at from 12 to 16 volts are employed. To signal 200 miles it is necessary to increase this to 7 amperes at 20 volts, using two ¼-inch sparks.

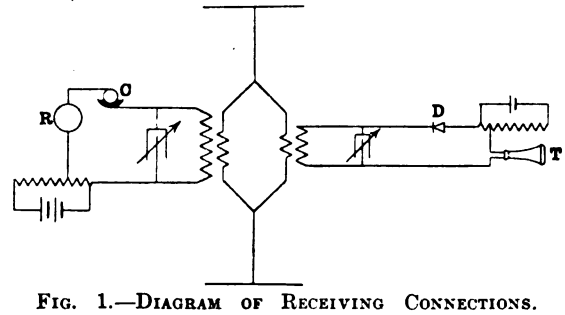

Fig. 1.—Diagram of Receiving Connections.

During the first two years the receiving was done solely with the Lodge-Muirhead steel-mercury coherer and recorder, but for the last six months other detectors and sound reading have been used in addition for practice. The arrangement of receiving circuits at present adopted is shown in Fig. 1, except that a looser coupling is employed with the telephone; it will be seen that the microphonic or lead-peroxide detector *D* and telephone *T* take the place of the coherer *C* and recorder *R*.

When the writer was last in Trinidad the American fleet of warships approached Port of Spain, whilst their transport with the most powerful signalling apparatus was in the harbour, about five miles distant. The wave-length of this ship was measured as 550 metres, and, when it was signalling with full power, it

Digitized by Google

was found impossible to receive readable signals at North Post from Tobago using the induction coil, even after altering the wave from 530 to 512 metres, and increasing the current to 7 amperes. Two other ships with waves of 510 and 500 metres respectively (as measured by the writer) could be picked up separately, though they were signalling at the same time, when they were 50 miles distant, and these did not interfere with the signalling from Tobago. As the North Post station does not possess a means of quickly altering the wave-length of the primary receiving circuit, this was kept constant and only the secondary was altered. The primary of the receiving transformer consisted of a single turn of wire, six inches in diameter, fixed in position, and the secondary coil was placed so that it could slide along the axis of the two coils. With the capacity in this secondary receiving circuit of 0·001155 mf. good signals could be received from the ship with a wave-length of 500 metres, to be cut out when the capacity was increased to 0·001165 mf. Signals from the second ship, wave-length 510 metres, were received when the capacity was still further increased to 0·001175 mf.; from the sound it would appear as if one of the ships were sending with an induction coil, the other using a transformer. When the American

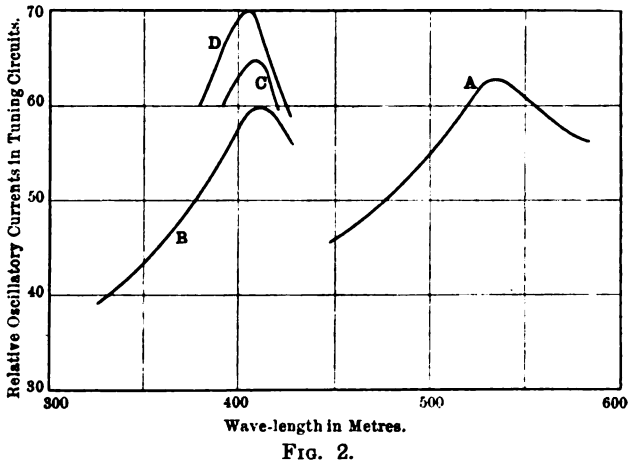

Fig. 2.

fleet was from 10 to 20 miles away the signals from the radio-telephone apparatus were apparent by a wavy line on the recorder and a buzz in the telephone, but the primary receiving circuit was too much out of tune to enable articulate sounds to be distinguished.

Considering the claims of absence from interference, when the lower capacity is raised, the writer decided to try this arrangement experimentally, but unfortunately he was only able to give a couple of hours to this work.

As even these preliminary experiments are of interest the results are given. In Fig. 2, A is the resonance curve under normal conditions of working, using a 5/16th inch spark, and with the induction coil taking 5 amperes with 10 volts across its terminals. A rough skeleton aërial was made 5,000 sq. ft., and raised above the earth so that the two carpets would be approximately parallel. As the aërial is on the slope of a hill, one side had to be raised 20 ft., whilst the other end was only raised 2 feet; the adjustment of the induction coil was not altered, but it now took 3½ amperes at the 10 volts, and the resonance curve *B* was obtained. The induction coil was then readjusted to obtain the best spark, and curve C was obtained, the coil taking 2 amperes at the same voltage. The earth capacity was next raised so as to be 4 ft. from the ground at the top end of the hill, keeping the other side as before; the curve D was then obtained with the same current. Raising the carpet another 2 ft. did not materially alter the readings. From these preliminary trials it is obvious, if a simple Hertz oscillator be employed, that by raising the earth capacity, larger oscillatory currents can be obtained with less power than with the lower capacity lying on the ground.

In the first trials of the system between Trinidad and Tobago, great difficulty was experienced from breaking down of the insulation of the oscillator, both at the mastheads and at the entry of the wires into the apparatus room. It is of much greater importance to keep good insulation with the simple Hertz form of oscillator, as developed by Lodge,

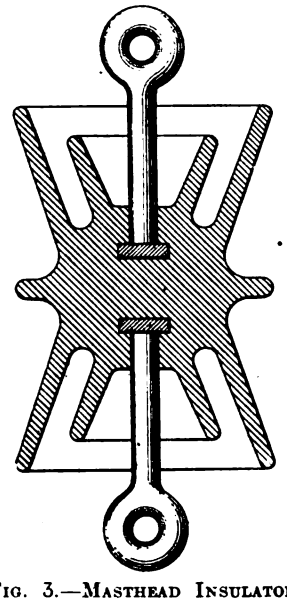

Fig. 3.—Masthead Insulator.
[From "Radio-Telegraphy," by C. C. Monckton (Constable).]

than with an aërial coupled to a closed type of vibrator; but complete success has been reached, even in the humid atmosphere of Trinidad, by using highly vitrified porcelain. The masthead insulators designed by the writer are of the form shown in Fig. 3. Using these insulators it is never found necessary even to lower the aërial for cleaning purposes; in fact, no attention is now required to be given to the aërial. The leading-in insulator now consists of an ebonite sheet

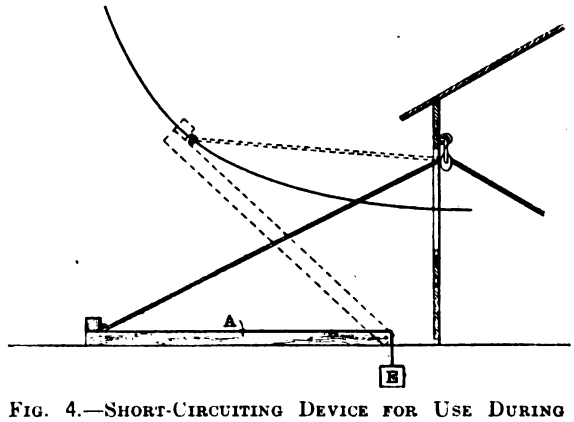

Fig. 4.—Short-Circuiting Device for Use During Thunderstorms.
[From "Radio-Telegraphy," by C. C. Monckton (Constable).]

which in itself is found useless, but it is separated from the building by porcelain rods.

The station at North Post has been struck by lightning on one occasion four times within ten minutes. The spark-gap is in a separate room from the rest of the apparatus, and the knobs had been brought together, whilst the wires had also been removed from the induction coil, so that the damage done was a slight fusing of the wires in the spark room. On the last stroke the aërial broke away at one of the masthead insulators. The writer has now adopted the method

Digitized by Google

illustrated in Fig. 4 to short-circuit the spark-gap during severe storms. The rod *A*, to which is fixed a copper strip, can be raised as shown by the dotted lines, so as to short-circuit the leads into the apparatus house.

From the experience of the Trinidad-Tobago working, the cost of oil for the engines for a station working up to, say, 150 miles without much signalling, would be £10 per annum, whilst for depreciations, repairs, and renewals about £100 should be allowed. In out-of-the-way places it is necessary to have two operators at each station to provide against illness, though only one is required to work the apparatus. The total annual cost of each station in the Trinidad-Tobago system is now £450 per annum; this allows for two operators at each station, labourers, messengers, supervision of the Public Works Department, and telephone rental. The average time for a message of twelve words to be transmitted from Port of Spain to Scarborough, including telephoning twice at both islands to avoid mistakes, is 20 minutes. The advantages of radio-telegraphy in the tropics is apparent from the fact that in this system the telephone causes more delay than the radio-telegraph.

AMERICAN VIEWS ON THE COMMERCIAL POSSIBILITIES OF METAL FILAMENT LAMPS

A PAPER entitled "The Status and Commercial Possibilities of High-Efficiency Lamps" was read by Mr. W. W. Freeman at the recent convention at Chicago of the National Electric Light Association. It was not the intent of this Paper to treat the lamp situation exhaustively or in detail, but merely to outline the principal characteristics and commercial values of the different lamps. The leading types of metal filament lamps now commercially available in America were classified as follows:—

Tantalum.—Efficiency, 2·0 watts per candle-power. Sizes, 40, 50, and 80 watts. Probable useful life double that of carbon lamp.

Tungsten—Efficiency, 1·25 watts per candle-power. Sizes, 40, 60, and 100 watts. Probable useful life double that of carbon lamp.

The Paper continues:—All of the above types of lamp produce a whiter light than the carbon lamp, and the equality of the light is generally regarded as superior. The filaments of the tungsten and tantalum lamps are much less sensitive to voltage fluctuations than the carbon lamps, and their candle-power performance is practically constant throughout life. The tantalum lamp, however, is best adapted to direct-current operation, the life being considerably shortened on alternating current.

The tungsten filament when not heated is very fragile, and the lamps must be handled with great care. Even with every possible precaution, the breakage in deliveries promises to be substantial for some time, at least, and this factor must not be overlooked in making calculations as to probable costs. The first lamps had to be used vertically, but, with reasonable care, it seems practicable to use the present lamps (except 100 watts) in any position. On account of the intensity of the light, it is desirable to use frosted-tip lamps with suitable glass shades almost invariably.

Figures are then given to show the saving that can be obtained in an installation of an aggregate of 2,400 c.p. by replacing 150 16-c.p. carbon lamps with equivalent lamps of higher efficiency. The cost for 800 hours is given as $720 for the carbon lamps, $460·8 for the tantalum lamps, and $288 for the tungsten lamps (assuming current at 12 cents per kw.-hour).

These reductions in prices represent a saving to the consumer in the cost of electric service through the use of the new lamps, provided he can so distribute them as to make them equally effective in illumination with the units previously used. This will often be impracticable, and perhaps possible only in exceptional cases where large units were formerly used or rearrangement of outlets is easy. In many, if not most, cases, the natural result from these lamps will be that the customer will obtain increased illumination at relatively, but not actually, reduced cost.

In regard to the policy which central stations should adopt, it seems to the writer that every improvement should be encouraged and offered to the public upon reasonable terms at the earliest moment practicable, and that the first reliable information concerning lamp developments should reach consumers through the lighting companies. If they do not promptly give their customers the facts, others will make erroneous and extravagant statements which will lead to misunderstanding and dissatisfaction.

It is evident that tungsten, or even tantalum, lamps cannot be thought of for free renewals, because of their extremely high cost. Furthermore, in any plan of distribution, the very limited supply must be recognised. In the United States in 1907 the demand for incandescent lamps exceeded 80,000,000 lamps, of which 20,000,000 were for increased business. To date, only about a half million domestic tungsten lamps have been manufactured, and, with the utmost factory expansion possible, not over 2,000,000 such lamps will be produced this year, or 2·5 per cent. of the lamp demand of 1907. While the supply of these lamps will increase rapidly, it is certain to be a matter of years before they can be obtained in sufficient number to largely displace the carbon lamps.

While it might seem that the natural demand for these lamps should come first from present customers, it must be recognised that the difference in the unit sizes and the substantial charge that must be made for the lamps, as compared with the free renewal policy with carbon lamps, common in the United States, will tend to retard the substitution of these high-efficiency lamps for the less efficient lamps, especially where small units are now used. In new work, however, where the wiring can be arranged especially for the new units, they can be used at once to great advantage, and in competition with the large gas units they should prove very effective.

The tantalum lamps appeared to possess great advantages until followed so closely by the tungsten lamps. Being a smaller lamp, both in bulb size and candle-power, than the present tungsten lamps, they can, of course, be used in many places where tungsten lamps are impracticable and where a more efficient lamp than the carbon lamp is desirable. It seems probable that if the tantalum lamps are to attain much use at present their sale must be pushed by the companies at prices involving a modest charge over the carbon lamps, say 25 cents each. With the life promised, companies can afford to put out these lamps in lieu of free carbon renewals with such an excess charge, and they will prove distinctly profitable to customers upon such a basis.

When we consider the tungsten lamps there ought to be no question of the demand, even at relatively high cost prices, and the expressions of opinion of scores of companies, show conclusively that the companies are well aware of the effective use to which they can be put in competition with other illuminants. At last it seems reasonable to believe we have an incandescent-lighting unit that can compete successfully with gas on even terms as to cost.

The only fear expressed from any source is that the demand for tungsten lamps from present customers may equal or exceed the present possible supply, and that the first effect of their introduction will be loss of revenue without compensating gains. The writer does not share this fear, but believes that tungsten lamps can be made immediately and increasingly useful to every company. The sizes of the units and other limitations previously referred to will necessarily offer restrictions in substitutions for other lamps in present installations. Furthermore, customers who are satisfied with their present electric service will not rush to purchase even high-efficiency lamps at $1·00 to $2·00 each in place of free carbon lamps, and there is no occasion for companies trying to persuade present customers to change to the new lamps. Such customers are entitled to a fair announcement about the types of lamps available to them and an opportunity to purchase them at reasonable and non-discriminating prices. Then the lighting company should feel free to bend all its energies unhesitatingly to securing new business and increasing old business, in both of which tungsten lamps can be used at once with very pronounced success.

While, doubtless, there will be instances where customers now using the larger incandescent lighting units can, and will, substitute tungsten lamps promptly and, as a result, obtain as good, or better, lighting service for much less money, yet for every such case there should be found scores of customers who are willing to pay something more than they are now paying in

Digitized by Google

order to obtain a great deal more light. There are also hundreds of stores in every city, the tenants of which are now using electricity sparingly in conjunction with gas, where all the lighting business should be secured with tungsten lamps without increasing the investment of the lighting company on account of services already installed. Possibly, however, the most inviting field for immediate exploitation of the large tungsten units is in competition with the hundreds of thousands of large gas lamps now in use and which type of lamp, in the opinion of the writer, can be rendered practically obsolete through intelligent campaigning with tungsten lamps.

The latter part of the Paper contained a collection of replies from the officials of a large number of American supply authorities to a series of questions on incandescent lamp practice. One of the questions was:—"What effect do you believe the commercial advent of the tungsten and other high-efficiency lamps will have upon the electric lighting industry, and what is your idea as to the best way of meeting the situation likely to ensue?" The replies to this question disclose a remarkable unanimity of sentiment. While there are a few who are fearful that the tungsten lamp will reduce their revenues and play havoc with them generally, the large majority of those who have expressed themselves seem to agree that the tungsten lamp will prove of immense benefit to the industry, as supplying a vehicle which for the first time will permit of real competition, as far as price is concerned, with gas and gasolene, and which, from its high efficiency and economy, will raise the standard of lighting, so that not alone will more customers be secured, but present customers will rather utilise this lamp to secure more light for the same money than the same light for less money.

STREET LIGHTING WITH METAL FILAMENT LAMPS IN SERIES

A PAPER was read by Mr. P. D. Wagoner at the Chicago Convention of the National Electric Light Association, dealing with use of tungsten lamps in series for street lighting.

In the early days of arc lighting the need of a smaller unit for lighting suburban and residential districts was keenly felt. To meet this demand the series incandescent system was developed, being first used in about 1880, at which time the lamps were used on circuits with open-arc lamps supplied with direct current from dynamos. Various methods of regulation were introduced from time to time, including the constant-current transformer, which was developed and placed on the market about 1902.

In the early history of series incandescent lighting, the life of the units that were used was approximately 150 hours, with an efficiency of 4 watts per candle-power. Improved manufacture of these lamps brought the figures to 3·5 watts per candle-power. This efficiency was obtained about 1885. The life of the 3·5-watt lamps at that time was from 200 to 300 hours, but, in the later development, reached an average life of 600 to 1,000 hours. For many years the latter figures remained unchanged, and the advocates of series incandescent street lighting were compelled to face the obstacle of comparative low efficiency. Only in recent years has the development of the tungsten lamp at 1·25 watts per candle placed the series incandescent system on a basis to compete effectively with other systems of street illumination.

Indications of most satisfactory tungsten life have been obtained in actual practice, and it would seem reasonable to expect an average life of 1,500 hours at 1·25 watts per candle. The initial efficiency seems to be maintained pretty generally throughout the life of the lamps, while with the carbon lamp it decreases from 25 to 50 per cent.

Generally speaking, there are two types of street lighting. The one employing a lighting unit of high candle-power, and the other a unit of low candle-power. There are sections of a city, such as alleys, residence and suburban districts, which may be more or less shaded by trees, and where the houses may be a considerable distance from the street, where the arc is not the ideal illuminant. Should a unit of high candle-power, such as the arc, be used in such a locality, the cost of illumination would be such as to necessitate a wide spacing of the lamps, resulting in illumination of widely varying intensity. It is in such places that the use of the tungsten lighting unit becomes important—in fact, a necessity. The introduction of the tungsten lamp permits of increasing the intensity of uniform illumination of such an installation without increasing the cost of energy above that of a system using carbon-filament lamps. The practical operation of such a system is simplicity itself, as the arcs for high intensity and incandescents for lower intensity may be operated in series on the same circuit.

Considered as a mere source of light, the series arc lamp is of higher efficiency than the tungsten lamp; but this fact does not necessarily mean higher illumination efficiency. As illumination varies inversely as the square of the distance from the source of light, and since, therefore, the intensity of illumination falls off very rapidly as the distance from the source increases, there are many cases in which a more uniform and, therefore, more satisfactory illumination can be obtained by means of incandescent lamps placed at closer intervals than by arcs of greater total light flux placed at longer intervals.

In the case of an arc lamp hung in the middle of a 30-ft. suburban road, its rays of maximum intensity being (in case of the magnetite or luminous arc) about 10 degrees below the horizontal, a large portion of the light will be wasted beyond the fences in the surrounding fields, where it is of no value whatever. The lighting of intermediate districts, between the principal business districts and the outlying districts, depends upon local conditions. In the residential section of cities having wide streets and long blocks, it may be found economical to place arc lamps at intersections of the streets and light the intervening spaces by incandescent lamps.

The Paper then proceeds to give some particulars of the system, and details the various sizes for which the constant-current transformer for series incandescent lighting has been standardised.

It is stated that lamps of 32, 40, and 60 candle-power have already been standardised. Higher candle-powers will probably be added later, as various arrangements for the suspension of the lamps have been devised. The ideal arrangement is to suspend the lamp in the centre of the street, though this is seldom practical. More often the poles are placed on one side of the street or an equal distance apart diagonally across the street; the lamps themselves being suspended by a suitable bracket attached to the pole, so as to project several feet over the edge of the curb, minimising the shadows from foliage, &c. This arrangement is not practicable with the ordinary Welsbach street lamp. As to the height of suspension, this depends to some extent upon the intrinsic brilliancy of the unit and the distance between units. In the carbon-filament lamp the height is usually from 10 to 12 ft., but with the tungsten, where the higher candle-power will be more popular, it should be higher;

Lamp.	Tungsten Incan.		Gem Incan.	Carbon Incan.	Nernst Horiz.	Welsbach Single.	Magnetite Arc.

Digitized by Google

probably from 15 to 18 ft. In all cases the lamps should be suspended at such a distance above the sidewalk or roadway as to avoid the rays shining directly in the eyes of a person approaching, but not so high that tree foliage will intercept the light rays.

There are two general forms of reflectors used with series incandescent lamps for street lighting. These include an old type, somewhat resembling an inverted cone. The lower surface is of white enamel or other suitable white finish. The objectionable feature of this type of reflector is that practically none of the rays emanating from the lamp strike the reflecting surface; in other words, the reflector does not serve the purpose for which it is intended. A new type, known as the "radial reflector," has also been developed, which consists of a stamped fluted steel disc about 22 inches in diameter, the under surface of which is finished in white enamel. This reflector serves as a protection for the lamp, directs the rays in the proper direction, and increases the effective illumination by about 20 per cent. The reflector is practically indestructible, and is made in one piece.

A table, comparing various systems of street lighting, is given on the opposite page.

In this table the life of the Welsbach mantle has been taken at 500 hours. However, there are certain authorities that give the average life of the Welsbach mantle at 300 hours. In the above comparisons the costs of poles and wires in the electric systems and posts and piping in the gas system have been disregarded, on account of the widely varying values, which are necessarily dependent upon local conditions; however, gas piping would ordinarily be more expensive than wiring for the electric system. For the same reasons, interest and depreciation have been disregarded, also labour of renewals except in the case of magnetite arcs, where renewal charges include trimming, electrodes, globes, tube renewals, and repairs.

In each of the installations the spacing of the units has been made such that the minimum illumination will be 0·006 ft. candle, even should alternate lamps be extinguished; with all lamps burning the minimum illumination—that is, the intensity midway between the lamps—would be about 0·024 ft. candle, which is ample.

ARMATURE COIL WINDING

IT has long been recognised that the accepted method of winding armature coils upon wooden formers is not only cumbersome but expensive, both in time and material, on account of the very high cost of having a separate wooden former for each separate coil. In practice it is found that these formers have to be continually repaired. Research has constantly been made in this direction, and one of the results was the recently published method evolved by Mr. Creedy for winding coils for semi-enclosed slots. In view of the importance of the subject it is interesting to examine the latest type of machine which has

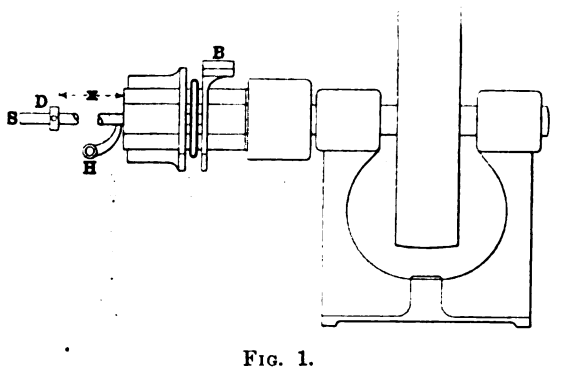

FIG. 1.

been produced for armature coil winding, and for this we are indebted to the Saxon Engineering Co., Ltd., of Stoke-on-Trent.

At a period when this firm was itself manufacturing dynamos the difficulty in former winding mentioned above presented itself to them as one which could be overcome, although there was at the time no satisfactory adjustable machine on the market. As a result, Mr. Cramp, of Manchester, and Mr. E. G. P. Bousfield, a director of the company, evolved the winding machine in its present state. This machine is perfectly adjustable in each dimension, and can therefore be used for winding any size of coil to the utmost nicety within certain

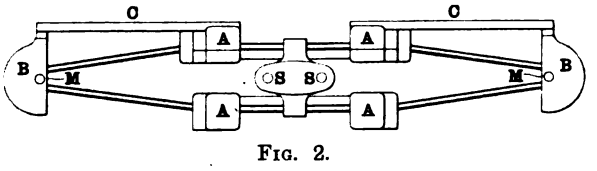

FIG. 2.

ranges. Moreover, when the coil is wound it can be "formed" with one movement of the machine so as to have the kinks at right angles to the coil in the most approved style.

Fig. 1 shows a side elevation of the machine as constructed by this company. It consists of a spindle carrying at one end a pulley and on an extension the adjustable device which is about to be described. Fig. 2 shows the end elevation, and Fig. 3 a plan of the device, also showing diagrammatically the course of the coil which is being wound upon it, this travelling along the path *BAA—BAA*. The fourth illustration shows Fig. 3 with the sliding head extended, and one is able at once to trace the familiar shape of a former wound coil as extended from the plain winding above traced. The machine consists of four slides *A*, which are adjusted by means of set screws, so that the outside measurement across each pair of slides is equal to the length of the winding which is enclosed in the iron of the armature. Two other slides *B* are connected to arms *C*, and are adjusted so that the distance from the outer edge of *A* and the inner edge of *B* is equal to the length of the coil which is required on the outside portion of the opened-up coil, as shown in Fig. 4. A collar *D* on one of the slide rods *S* (Figs. 1 and 4) is adjusted so that the distance of travel of the sliding head is equal to the distance between the two portions of the coil which are included in the iron of the armature. The slots in the slides *A* and *B* are opened or closed by means of set screws or movable washers between the plates respectively, so

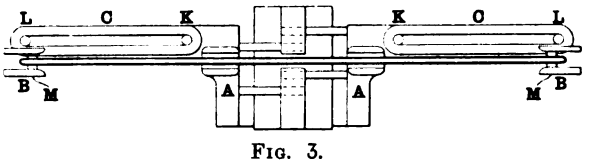

FIG. 3.

as to give the required thickness of coil, and the machine is then ready for winding the coil.

One end of the wire is fastened with a single twist to the screw provided on the machine for that purpose, in order to fix it to the machine in such a way that it will not slip off at the commencement of the winding. The machine is then rotated, and the wire guided through the slots till the required number of turns have been made. When this has been accomplished, the steady pins *KK* and *LL* are removed, leaving the arms *C* and slide *B* free to move about their centres, and by means of the handle *H* the whole of the movable block is drawn forward till the collar *D* stops further movement, giving

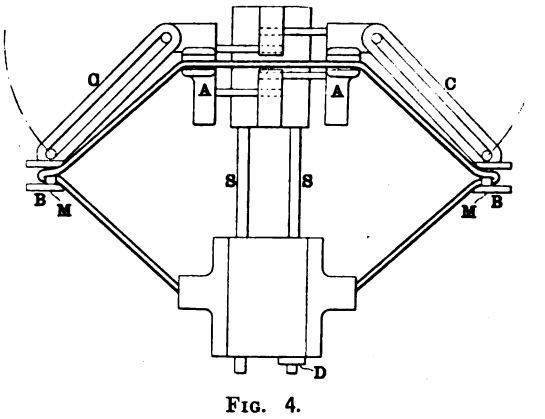

FIG. 4.

the coil the required shape. After binding with tape or other material, the coil is ready for removal from the wing nuts at the end and slipping off the guide plates *B*, after which the wing nuts can be replaced for another coil.

There are now two forms of machine in use. In the smaller and original machine the winding gear, together with head stock

Digitized by Google

and pulley, is practically as illustrated. The sizes of coil wound by this machine are 5 in. long by 3 in. broad up to 17 in. long by 10 in. broad, or slightly over, and wire up to a size of 14 L.S.G. can be taken. Among the users of this machine may be mentioned Messrs. Mather & Platt, Ltd., the Lancashire Dynamo & Motor Co., Messrs. Campbell & Isherwood, Messrs. the Electric Ordnance & Accessories Co., Ltd., Messrs. McWhirter & Sons, Glasgow, De Beer Consolidated Mines, Ltd., South Africa, the Electrotechnische Industrie of Holland, the Sunderland Forge & Engineering Co., Ltd., and other firms.

The second machine, which was designed at the request of the Admiralty, has a precisely similar winding appliance, except that it is on a larger scale, and will take coils from 6 in. long by 3 in. broad up to 21 in. long by 12 in. broad, carrying wire up to 8 L.S.G. It is, however, very much more complete in its arrangement, as it stands on its own bedplate, with back gear for giving four useful speeds, and has a friction clutch for stopping or starting the machine instantaneously, and guide pulleys for taking the wire direct from the rotating arm. The machine is patented in Germany, France, and the United States as well as in this country.

It will be seen that for simplicity of operation and certainty of action, the machine described above marks a distinct step in the economical production of electrical apparatus.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

ERNESTO STASSANO contributes an article to *Electro-chemical and Metallurgical Industry* of August upon the "Treatment of Iron and Steel in the Electric Furnace." He refers to previous articles which have appeared upon the subject in which the difficulties of reduction in the electrical furnace have been accentuated. Stassano states that he has overcome these difficulties, and says that the treatment of iron ores and iron agglomerates has passed the scientific experimental stage, and has taken its place in the industrial arts. He shows that a maximum consumption of 4 h.p.-hours is quite enough to produce the same results in an electrical furnace as 1 kg. of coal in a blast furnace, and if that energy is produced by water-power, the cost is 29s. 2d. per h.p.-year, or about ½d. per h.p.-hour, and with fuel at 16s., the electric furnace is on terms of equality with the blast furnace; fuel in this country, however, is very much less than 16s. per ton, although in Italy it may be 16s. or more. The furnace should fulfil the following conditions. (1) The chamber in which the electrical energy is transformed into heat, and in which the metallurgical process takes place, should be protected from the atmosphere. (2) The heat should be generated from the electricity at the highest temperature possible. (3) The whole apparatus in which the various operations are carried out should be designed and built so as to work continuously at full charge.

He then describes his well-known rotary furnace consisting of a sheet-iron cylinder with a conical roof lined on the inside with refractory material. The chamber for melting the metal is also in the form of a cylinder, and is provided with a fire brick cupola. Openings are provided for the electrodes, which are arranged to project towards the centre of the furnace, ends being at such a distance apart that arcs are readily formed and at a convenient distance from the bottom. The electrodes are externally protected by means of water-cooled cast-iron cylinders fitted to the exterior of the furnace. The movement of the electrodes is controlled by guide-rods outside the furnace. A metallic rod is fixed to the end of the carbon electrodes, the end of which is connected to a flexible cable, which passes below the furnace to the current supply. At the top of each of the water-cooled cylinders for protecting the electrodes a small hydraulic-pressure cylinder is provided, the piston rod of which is connected with the metallic rod of the electrodes, and thus the movement of the electrodes is controlled, and the distance between their terminals within the furnace is regulated. The lower part of the furnace is surrounded by an L-shaped rail of cast-iron, which rests on the inclined top of the pit-wall, and thus forms the support of the furnace. The longitudinal axle of the furnace is, therefore, inclined by a certain angle from the vertical. The furnace is revolved by means of gearing at the bottom. At the head wheel insulated copper rings are attached, which, by means of copper bars and elastic cables, transmit the current to the electrodes. The current is supplied from the generator to a series of brushes disposed round the top of an iron support in the middle of the pit. A distributing valve is placed on the top of the stationary iron support, which distributes the water for the pressure regulators and the cooling cylinders protecting the electrodes. The metal is discharged from the bottom of the melting chamber, and opposite to it another opening is left for charging. In the centre of the brick cupola an exit is provided for the gaseous products of the reactions. Through this exit the gases escape into a metal tube shut by a sand valve and leading to a vessel filled with water from which they may escape into the open air or can be used otherwise. This arrangement prevents any entering of air from the atmosphere into the melting chamber; neither can air get in on opening the charge hole, since the pressure inside is higher than outside, on account of the higher tension of the gases at the elevated temperature inside.

Although the arc temperature is very high, yet this electrical furnace will not overheat the charge in a detrimental way. Indeed, the chief characteristic of this furnace is that it is an air-tight chamber with a thermic source in its centre, radiating heat at a very high temperature. Evidently the temperature of the chamber will increase and tend to reach gradually that of the arc, but will not reach it. Experience shows that if the right proportion is used between the charge capacity of the melting chamber and the quantity of heat produced, the operation proceeds satisfactorily without overheating the charge. It seems clear, therefore, that refined iron may be obtained *from ore directly* in this furnace if it is charged with iron ore mixed in the right proportion with a reducing agent and fluxes able to transform the gangue into slag of a suitable composition to absorb the impurities of a single operation. Such a charge will be gradually heated out of contact with air. The flux cannot absorb oxygen, and maintains its quality also at an elevated temperature, so that it is able to react when the right temperature has been reached. Among the different oxides contained in commercial iron ore, that of iron is the first one which is reduced. The remaining oxides (SO_2, MnO, MnO_2, CO, MgO, &c.) are, therefore, left without reducing elements, and hence forced to pass, with the assistance of the flux, into the slag. In the same way, if pig-iron or iron scrap is used, mixed with the slag-forming materials, the pig-iron and impure iron may be successfully refined in the same furnace.

This furnace can be used for the extraction or iron directly from ore as the refining of pig-iron and raw iron. As the design and operation of the furnace exposes the material to the most elevated temperature in a neutral atmosphere, it is easy to produce iron of the finest and purest quality. As the atmosphere in the furnace is chemically neutral, and the operation may be carried out at will for any length of time, the metal may be almost completely freed from all impurities without the risk of oxidation. Stassano considers that the electric furnace can be as well used for the direct extraction of malleable iron directly from the ores as for the purification of pig-iron, scrap iron, or steels; the furnace is thus very valuable in a country lacking in fuel, but which is rich in water-power. The furnace may also be used as a valuable auxiliary in the ordinary iron and steel industry where blast furnaces, open hearth furnaces, and Bessemer converters are employed. Modern engineering industry requires special iron and steel for high-speed tools, and these cannot be chemically manufactured by ordinary metallurgical operations, but for this class of work the electric furnace is of the very greatest value. It would, therefore, appear that the electric furnace has come upon the scene in time to help or act as an adjunct to the old iron and steel industry, because its particular properties permit of the refining of material which has been manufactured by the older processes. At Turin the Stassano furnaces in the artillery shop are usually treating pig-iron and scrap iron, the product being generally manufactured to produce mild steel castings for railway wheels, automobiles, and for general mechanical purposes. In the article tables are given which show the efficiency of the furnace and the energy consumption, and make clear that up to a certain point the larger the furnace the greater the efficiency. For example, if steel is refined in a 220-h.p. furnace, it is found that 1·26-kw. hours were required per kilog. steel, whereas with a 100-h.p. furnace the energy required for the same production of steel was 2·3-kw. hours. The operating expenses for electric furnace work are low. The consumption of electrodes, expenses for repairs and insulation, and salary expenses are low, as experience has shown. During the long operation in artillery works and in Stassano's steel works, the consumption of electrodes was not more than 10 kw. per ton of metal. The expense for lining per ton of metal was on the average about 8s. 3d., except in rare special cases, where it rose to 11s. 5d. to 12s. 5d. per ton. With regard to wages, three men are quite sufficient for a furnace of 300 h.p., and five men, at the utmost six, can attend to a furnace of 1,000 h.p. when working with cold material, while for refining steel or reducing ore four men will be sufficient. The first furnace of the kind was erected at the artillery works of Turin. It consists of a 200-h.p. furnace operating on a three-phase current supply by the Societa Ellettricita Alta Italia. This furnace was first worked in the spring of 1903, and it has since then been kept in regular operation, about 2½ tons of steel being produced daily. The second plant was installed at Stassano's steel works in Turin. The installation consists of two 100-h.p. furnaces, which are generally used for experimental work, two 200-h.p. furnaces, one tilting and the other rotary, and two furnaces, one stationary and the other rotary, having a capacity of 1,000 h.p.

At the Bonner Fräser Fabrik in Bonn, Germany, a 200-h.p. rotary furnace has lately been installed, which is supplied by a three-phase current from the Berggist-Brühl electricity works, where the power is obtained from steam engines. The current is brought in at 5,500 volts, and by means of a transformer situated near the furnace it is reduced to 100 volts between phases.

TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION

Communications to the Discussion on Prof. Carus-Wilson's Lecture on Rail Corrugation

THE lecture on "Rail Corrugation," delivered by Prof. C. A. Carus-Wilson on July 10th at the last meeting of the Annual Congress of the Association, was discussed on Friday, July 24th, and a full report of the discussion was given in ELECTRICAL ENGINEERING, July 30th, page 173. An abstract of the lecture was given on page 107 of ELECTRICAL ENGINEERING for July 16th. It will be remembered that the lecturer stated that in his opinion corrugation was due primarily to the wheels running on unequal diameters, this causing skidding of the smaller wheel. This skidding, if grit was present on the rail, became intermittent, the period between the skids depending on the limiting twist of the axle.

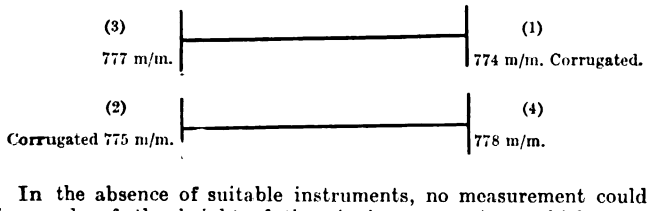
The discussion was opened by Mr. H. M. Sayers, who expressed the opinion that intermittent slipping would have the same effect as the intermittent skidding described by the lecturer. Such intermittent slipping could be caused by the sudden rise of motor torque when two or more notches of the controller were passed over without a pause. Mr. J. R. Salter suggested that the molecular change in the iron rails due to magnetisation might have some influence. The importance of ensuring uniform flange pressure was emphasised by Mr. J. S. Warner. Mr. S. Sellon objected to the tyre section shown by the lecturer, and called attention to the wear which must take place on the flange and rail-head before check-cutting can occur. He did not think unequal diameters essential for the production of intermittent skidding. The corrugations on the old Brixton cable tramway lines were put forward by Mr. J. Welling in support of Prof. Carus-Wilson's theory. Prof. Carus-Wilson replied very completely to all the questions put, but has sent in the following written communication with regard to his reply to Mr. S. Sellon:—

Prof. CARUS-WILSON (communicated): With regard to Mr. Sellon's criticism of my Fig. 2 (see ELECTRICAL ENGINEERING, July 16th, p. 107), he says, "by the time the wheel has arrived at that stage in which he has shown it the other rail is (worn) down in proportion." I think this explains where we differ. Mr. Sellon takes no account of the fact that along with the check cutting on the one wheel there is always a thinning down of the flange on the other wheel, so that the rail has not to be worn away "in proportion" to the cutting of the check. It is this thinning of the flange that makes check cutting on the straight possible, and justifies the practical accuracy of Fig. 2.

The following written communications to the discussion have also been received.

Mr. FRED BLAND (Tramways Department, Edgar Allen & Co., Sheffield) wrote as follows: As a manufacturer without an "axe to grind," or even a grinder to sell, I have taken considerable interest in this subject, but have no theory to put forward. I wished to place before the members an interesting addition to this subject, obtained during a recent visit to the Continent, one, I believe, that has not been touched upon as yet. The fact in question is the corrugations upon the tyres of the tramcar wheels of the Helsingborg tramways, which are plainly to be seen upon the tread of the tyres. The following information with regard to one car with such corrugated wheels may be of interest:—

(1) The diameter of the wheels and the relation to each other stand thus:—



In the absence of suitable instruments, no measurement could be made of the height of the single corrugations which were noticed several times, and which in this case were especially strong. This corrugation on the diagonal wheels was found in several cases, but also upon three wheels of one car, and upon four wheels of another car. The corrugation takes place upon the smallest wheel of the same axle, and in relation to both axles upon diagonally situated wheels.

(2) On the opposite wheel no corrugation was found, in spite of an exact and careful examination, whereas, as stated above, upon one car corrugations exist upon three wheels, and upon all four wheels on another car.

(3) The corrugations first occurred on a curve of 200-m. radius, which was run over quickly, and upon this spot the under surface was very bad, and although all sorts of trials were made, the lie of the rails could not be improved, and the corrugation was very strong.

(4) They think there is a possibility that on this spot the corrugation took place upon the wheels, and these transferred the corrugations to other portions of the track, and they draw this conclusion from the fact that the first corrugation was noticed after 1½ year's wear, and now for the first time after about five years' corrugations have occurred upon the greater part of the remaining track.

(5) Further observations are now being made as to the increase, or otherwise, of these corrugations.

(6) The corrugations on the tyres correspond exactly with the corrugations on the rails in form and length, and are distributed at about 7—8 c/m. distance from summit to summit on the circumference, and the cars which run with corrugated wheels make a peculiar buzzing noise when running quickly.

(7) The tyres are Krupps' steel, of at least 80 kg. per square mm., and are twisted off in the middle after running 50,000 kilometres.

(8) The rails are Phœnix rolling—section 25 B—tensile strain 70 kg. per square mm., and at least 45 per cent. carbon.

(9) Brakes shoes are ordinary gray iron, but in their opinion these are not a contributory cause; "flats," caused by careless breaking, were often noticed on the tyres at first, but not for the last three years, and they do not think that the "flats" on the tyres led to corrugation.

I have to thank Mr. t'Serstevens, the Secretary of the International Tramway Association (of which I have the honour of being a member), for the details, which I believe will be given at the forthcoming Tramway Congress at Munich in September, in connection with the Commissioners' Report upon Corrugation.

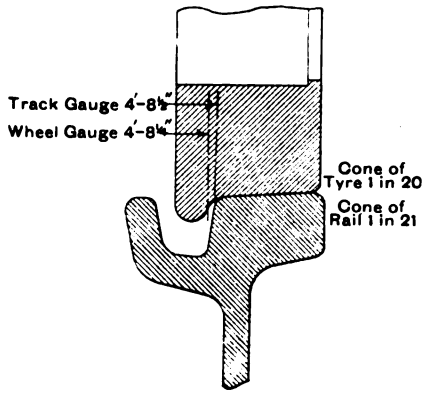
Mr. W. F. IRELAND (Rolling Stock Superintendent, L.C.C. Trams.):

The wheels as arranged on the model truck, *i.e.*, with one running on its flange, produce in effect a conical roller. This obviously will not roll in a straight line without the smaller end slipping on its path, but would run perfectly on a curve, the radius of which is identical with that of the natural rolling circle of the cone. Would not the reason for the accentuated slip, which is shown in the Professor's model to be due to energy stored up in the spring when track is sanded, be largely responsible for wear of the check, and not a result of it? It will be obvious that if a pair of wheels be considered as a cone, forced to travel in a rigidly defined path, which does not conform to the natural rolling curve of the cone, its axis will never be at right angles to its forced path when rolling; therefore, the flanges of the wheel would be constantly slipping on the check of straight track, as occurs on the inside rail of a curve track.

Professor Carus-Wilson says the flange cannot come into contact with the check until considerable wear has taken place. I cannot agree with this statement, as it will be readily seen that, given the condition of wheels or track to produce what is virtually a cone-shaped roller of a pair of wheels, check-cutting can be produced without wear having taken place, as, for instance, if tyres of different diameters are fitted to a pair of wheels, that pair of wheels will travel sidewise along the track and produce check-cutting and slip simultaneously. The effect of a cone being forced to roll in a straight line is to produce positive slipping points at the larger end, the intervals of which depend largely upon the coefficient of adhesion between the cone and the path and the strength of the cone to resist torsion. Therefore, with a low coefficient of adhesion the intervals are short and scarcely discernible, but with high coefficient of adhesion the intervals will be longer and dependent upon the torsional resistance of the axles. Are the intervals of slip, or pitch of corrugations, longer where smaller diameter axles are used? This should be so if both wheels are acting to produce corrugations on one rail only, in virtue of their different diameters at the running surface producing a conical roller similar in effect to the Professor's model when the brass strip is placed under the flange. Are any cases of corrugation known where the rail-

Digitized by Google

head and tread of wheels are flat? Burton-on-Trent have a flat-headed section of rail and flat-tread wheels. If these rails do not show signs of corrugations on straight track, have they done so after wheels with conical treads have been run over them, as, for instance, after the Midland Railway Co.'s cars



Sketch showing Relative Positions of Standard Tyre and BSS4 Track Rail. Half-size

obtained running powers over the Burton system? If the action of a cone forced to run in a straight path—when by reason of some defect, either in the rail-head or the wheels, the pair of wheels form the cone—tends to cause corrugations, these corrugations would, of course, only be formed on one rail by any particular pair of wheels, and the reason for both rails being corrugated would be accounted for by other pairs of wheels forming corrugations in the opposite direction.

Is it not reasonable also to conclude that *each wheel*, owing to the shape of the tread and its path (*i.e.*, the head of the rail, being conical), naturally desires to follow a circular path, but is forced to follow a straight one by the resistance of the axle, and should produce exactly similar effects on each rail simultaneously without reference to any torsional elasticity of the axle, just as the *pair of wheels* forming a cone does on one rail, and having regard to torsional elasticity of the axle. If this is so, would not the axle be subject to a constantly changing bending moment, and have some bearing on the question of broken axles? It is noteworthy that nearly all axles which have broken in London have done so at a point where this bending moment would be a maximum, *i.e.*, close to the outside of the wheel-boss, and not at a point where torsional stress would be a maximum, *i.e.*, the inside of the wheel-boss on that side of the axle on which the motor is suspended.

I should be glad if an explanation can be given as to the reason for both rail-head and wheel-tread having almost exactly similar inclination (see sketch of wheel and rail opposite). Assuming for the moment that wheel and rail perform the function of a rack and pinion, where the rack is stationary and the pinion rotary, would any sane engineer make the teeth with an inclination of 1 in 20 and expect to get equal wear over the whole face of the teeth?

Now, if one cone, as represented by the pair of wheels, having different diameters at their running surface, can produce corrugations on one rail, why should not each wheel do likewise, seeing that about two inches of the running surface is also a cone? Take, for instance, a wheel which has a diameter at the throat side of the tread is 30 in., and an inclination of 1 in 20; the diameter at the outside of the tread 2 in. wide will be 29·8 in. Every revolution of this wheel at the 30-in. diameter has travelled a distance on the track of 94·248 in., while the outside of the tread will only have travelled 93·620 in., *i.e.*, a difference, of, say, ⅝ in. per revolution. The question is now—What becomes of this ⅝ in.? Presumably the whole of the tread is equally loaded, and slip under these conditions would appear to be inevitable. I am not prepared to say that this is the cause of corrugations, but it is remarkable that where the inclination of the wheel tread and rail are similar, the wear of the rail is wavy in form and of a more pronounced nature than where considerable differences of inclinations occur, as where some cars have their wheels worn more or less flat. I have in mind the Council's subway tracks, where all the wheels were turned to exact diameters, and the inclination to gauge, the trucks built perfectly square, the cars suspended on swing bolsters and with centre-bearing swivels well lubricated; corrugations appeared within a few days of running, certainly before any wear of the check was discernible. The track in this case is laid on wood sleepers and is more or less flexible; therefore the weight on the wheels would tend to cause the rail to set itself to the inclination of the wheel-tread (after the manner of a self-aligning bearing) more readily than is the case where the rail is laid on a solid concrete foundation. It will no doubt occur to some that if slip goes on at each wheel-tread the effect would be such as to produce such minute waves as to be scarcely worthy of consideration, because the effect is not apparently accumulative to the same extent as where the pair of wheels form the cone in which the accumulation takes place in the form of torsional stress in the axle, but I think perhaps accumulation takes place in the form of bending stress of the axle in the form sometimes seen in a line shaft where heavily loaded in the centre between bearings.

RECENT WALL PLUGS

We are able to illustrate a few of the newest additions to the long series of wall and floor sockets and plugs which have been brought out from time to time by Messrs. A. P. Lundberg & Sons, and are described in a new list which they are just issuing. Fig. 1 shows the intermediate of the three sizes known as "Dot," "Universal," and "Magnum," of a design of plug the interior of the large size of which is seen in Fig. 2. The bases are of vitreous porcelain, and their covers are attached by means of the contact sleeves themselves. Their simple construction enables the price to be kept low. Both these and the ordinary plugs can be arranged with hollow-tube prongs and pin contacts in the sockets for heating circuits in order not to be interchangeable with those belonging to the lighting circuits. A special pattern of flush floor socket, with or without hinged brass lid, is another feature of the list, and also a sunk pattern, to which a brass cap flush with the floor may be screwed. This is particularly intended for dining-rooms which may occasionally be used for dancing. There are also a number of neat designs of semi-flush wall sockets projecting only a short distance from the wall, and these can be supplied without the ornamental fronts to firms who prefer to fit their own decorative designs. We have already described and illustrated Messrs. Lundberg's so-called "clincher" pattern of connection (Electrical Engineering, July 2nd, page 41). Fig. 3 shows a very compact form of plug for use where space is limited. With the exception of the last named, practically all these fittings can be supplied with three contacts instead of two for special purposes.

ELECTRICALLY-DRIVEN FIRE PUMPING STATIONS IN NEW YORK

A DESCRIPTION of the high-pressure system of water supply for fire protection, worked by electrically-driven pumps, which is being installed, is given in the *Electrical World* (New York). The present scheme includes four pumping stations, two in Manhattan and two in Brooklyn. One of these is already available for use, and the others are nearing completion. The pumps are operated by induction motors, and the aggregate rating of the set already installed is 15,000 h.p.

The high-pressure service in Brooklyn serves an area of 1,360 acres, and, when the system is in full working order, any one of the 700 special hydrants will be able to supply water at a pressure sufficient to throw it upon flames beyond the reach of ordinary fire engines. With the eight pumps at the two pumping stations at work, 48 streams of water may be concentrated at any part of the system with a pressure between 200 lb. and 150 lb. per sq. in. The pumps can force streams of water 700 ft. up through standpipes of high office buildings, &c. About 22 miles of special mains have been already laid.

The main pumping station in Brooklyn is at Joralemon and Truman Streets, near the East River. This station is nearing completion, and will contain five multiple-stage centrifugal pumps directly coupled to 800-h.p. three-phase induction motors. The other station, at St. Edwards and Willoughby Streets, is completed. The equipment consists of three Worthington centrifugal pumps, each of which is driven by an 800-h.p. induction motor. Current is obtained through special duplicate feeder cables from the Gold Street station of the Edison Company at 6,600 volts, which voltage is applied directly to the terminals of the motors.

Three cables run from the Gold Street station of the Edison Company to the Joralemon Street pumping station, and every precaution known has been taken to render the service reliable. The service is further safeguarded by the interconnections between the Gold Street and the Bay Ridge stations of the Edison Company, and between the storage batteries connected to the system. These connections afford a guarantee of almost absolute continuity of service; but in case of some unforeseen catastrophe by which both these sources of supply might be cut off, there are cable connections with the power stations of the Brooklyn Rapid Transit Company and also with the system of the New York Edison Company, so that the city may draw its electrical energy from any one of all the large generating stations in Brooklyn or from any of the stations of the New York Edison Company in Manhattan. By the terms of the contract the Edison Electric Illuminating Company must install and maintain sufficient electrical machinery, cable, &c., to permit the starting of any three motors in one pumping station simultaneously whenever required.

A special system of telephones connects the pumping stations and the power stations. The pumps are required to take full load in about one-half minute's time, so that when a fire is reported, the pressure on the mains will be high enough for all requirements by the time the firemen reach the scene and attach the hose. By means of the telephone connections available, the firemen can have the pressure increased or diminished as required. The contract price for the electricity supplied by the Edison Electric Illuminating Company is $3,660 per month as a readiness-to-serve charge, and $0.015 per kw.-hour for all energy used.

The Manhattan system comprises about 63 miles of mains varying in diameter from 12 to 24 in. Two pumping stations are provided: one near the Gansevoort Market on the Hudson River, and the other at the corner of Oliver and South Streets, near the East River. Each station will contain five pumping units, and have space reserved for three additional units.

The pumps are of the horizontal, multi-stage centrifugal type, each pump having six stages and being able to deliver 3,000 gals. of water per minute against a discharge head of 300 lb. per square inch, when operating at 750 r.p.m. with a suction lift not exceeding 20 ft. The pumps are designed so that the discharge pressure can be varied between 100 lb. and 300 lb. by means of a special regulating valve. The pumps are of Allis-Chalmers make, and each is direct-connected to its motor by a special flexible coupling. The motors are designed for operation on three-phase, 25-cycle, 6,600-volt circuits like those in the Brooklyn stations. In starting, an iron grid resistance is connected in the secondary circuit, and gradually cut out by means of a hand-wheel on the motor panel. When the resistance is cut out, the rotor is short-circuited by means of solenoids, controlled from the main motor panel through auxiliary switches. The controllers and motors are so designed that the pumps can be brought to full speed from standstill in approximately 30 seconds An interlocking arrangement is provided so that the motor cannot be connected to the line when the rotor is short-circuited The rates charged by the New York Edison Company on condition that the entire equipment in both stations shall not be operated simultaneously is $24 per year per kilowatt rating of motors connected as a readiness-to-serve charge, and $0·15 per kw.-hour for energy used. The electric energy for driving the motors is taken from the mains of the New York Edison Company, the current being at a potential of 6,600 volts. Each pumping station is connected to the Edison generating station by two three-phase cables, in addition to two reserve feeders from Edison sub-stations.

In order that there may be no delay occasioned by priming the pumps when they are to handle salt water, three motor-driven vacuum pumps are provided. A system of signal boxes has been so designed that a fire in any part of the district can be watched from at least one telephone box, and orders readily transmitted to the engineer at the pumping station in regard to the requisite pressure and the quantity of water required, as well as to use of fresh or salt water.

Special precautions have been taken in laying the water mains to avoid liability to freezing, and during the winter, water will be pumped slowly through the pipes from one station to another at intervals.

PROGRESS OF THE ELECTRICAL INDUSTRY

An American View

AMONG the Papers read in the month of May, before the thirty-first Convention of the National Electric Light Association at Chicago, was one by T. C. Martin, representing the report of the Association's "Committee on Progress." Referring first of all to the growth of the industry in America, the report says that the year 1907, which began with evidences of splendid prosperity on the part of every well-managed supply company, ended in gloom, with output lessened, income diminished, and every effort strained in the direction of economy and restricted expenditure. There are, however, already marked signs of recovery, and the consumption of electrical energy has regained in large measure the lost ground of the past six months.

Number of Stations in Operation.—The total number of American stations up to April, 1908, would appear to be 5,037, or, including 396 Canadian and 62 Mexican, a total of 5,495 for the North American continent. The number of stations in Germany up to April, 1907, is 1,526 (see ELECTRICAL ENGINEERING, Vol. III., page 554), and of this number 1,025 are under State or municipal control. In the United States, the opposite is the case, the stations in four cases out of five being under private control. The large power loads obtained in Germany are remarkable, considering the small size of most of the stations. According to the latest statistics for France, there were on January 1st, 1906, no fewer than 1,413 generating stations, over two-thirds of which were partly water-power stations. Of these 831 stations were purely water-power stations. The report then gives at length the terms of the agreement between the Paris Municipal Council and the Electric Lighting Companies with regard to the future of the electricity supply in Paris. These were given fully in ELECTRICAL ENGINEERING, Vol. I., pp. 543, 950, and Vol. II., p. 743. The statistics for England, says the report, are of interest, more particularly because they fail to show the power of expansion so manifest in the American and German data. The connections to the mains reached a total of 1,100,000 kw. by the end of 1906, two-thirds of which was under municipal control.

Rates and Regulations.—No questions during the past year have occupied greater attention on the part of electric light and power companies than those which concern relations with the municipality or the State, and which have to do with the control of public service corporations by boards or commissions. Incidentally, there have been decisions of importance by these bodies and by the courts affecting rates. One of the most

Digitized by Google

interesting cases is that in which the Wisconsin State Railway Commission has dealt with the application of the La Crosse Gas and Electric Company for the power to charge higher rates for electrical energy than had prevailed. The Commission agreed that the net earnings were not enough to meet ordinary depreciation charges, much less any interest on the investment, and allowed the revision of charges. Again, as a result of a recent controversy between the Minneapolis General Electric Company and the officials of that city, several expert investigations were made, and the correctness of the theory of readiness-to-serve charges in connection with electric light and power business was upheld. That is, the rates given to any individual customer should be dependent upon the fixed charges on the investment necessary to serve him, plus operating expenses, rather than on the average expenses of serving all classes of customers. Rates have been readjusted or modified in one or two of the leading cities in America during the past year. The rates to be charged by the Commonwealth Edison Company of Chicago have been fixed by the Chicago City Council for the period between August 1st, 1909, and July 31st, 1912, as 6½d. per kilowatt-hour up to the equivalent of 30 hours' use of the consumer's maximum demand, and 3½d. per kilowatt-hour for all energy in excess of that. A discount of one halfpenny per kilowatt-hour from the primary rate is to be allowed on all bills paid within ten days.

The Union Electric Light and Power Company of St. Louis has recently put in force a new system of rates which differs considerably from the typical systems in use. The fundamental principle of the system is that the customer's rate is based on the minimum monthly guarantee he is willing to make per horse-power or per 50-watt lamp connected. For example, the customer having less than 100 lamps pays 6d. per kilowatt-hour if he guarantees only 5d. per month per lamp. If he guarantees 33d. per month per lamp he need pay only 4d. per kilowatt-hour. By guaranteeing 23d. per month per lamp the customer gets a rate of 5d. per kilowatt-hour. The rate is also made lower as the number of connected lamps increases. For example, a customer guaranteeing 5d. per month per lamp and having less than 100 lamps pays 6d. per kilowatt-hour. This is reduced by steps until for 3,000 lamps or over the rate is 3d. per kilowatt-hour, with a 10d. per month per lamp guarantee. For the 23d.-per-lamp guarantee the customer with less than 100 lamps pays 5d. per kilowatt-hour, while the customer with 3,000 lamps pays 2·6d. per kilowatt-hour.

All these rates are subject to further discounts based on hours' use and quantity. The discount made according to the equivalent daily hours' use of the entire connected load starts with a 6 per cent. discount for a kilowatt-hour consumption equivalent to 1 hour's use per day of the connected load, rising by steps to 25 per cent. discount for a kilowatt-hour consumption equivalent to 18 hours per day of the connected load. There is also, in addition to this, a discount based on the amount of the bill, which is from 5 per cent. on bills of under £2 to 56 per cent. on bills of over £1,800 per month. The power rates are on the same plan. A 1-h.p.-motor customer pays 5d. per kilowatt-hour if he guarantees 4s. per month per horse-power. If he guarantees £1 10s. per month per horse-power he pays 2½d. per kilowatt-hour. The rate also depends on the horse-power connected.

New Central-Station Work.—It cannot be said that anything particularly new has occurred in central-station design and construction during 1907. Perhaps the most striking novelty has been the completion by the Patapsco Electric and Manufacturing Co. of its new dam and power-house in one, on the Patapsco River, about 15 miles below Baltimore. The plant is unique in that it is placed entirely within the dam itself, and is thus completely under water. (This power-station was fully described and illustrated in Electrical Engineering, Vol. II., p. 472.) With regard to power-transmission, attention may be called to the 100,000 volt transmission system of the Grand Rapids-Muskegon Power Company for light and power. Since the early part of 1907, 35 miles of steel tower line have been built for operation at this pressure, using the new suspended type of insulator. Five of these insulators, hanging horizontally one above the other in series, are used to insulate the line. Each porcelain suspended insulator is 10 in. across, and the rated voltage that it will withstand is 23,000 per "link." (See Electrical Engineering, Vol. II., p. 948.)

Advertising Signs.—The streets of the leading cities in America are still brilliant with electric signs, and attention is now being directed to the lighting of posters. In Chicago, Kansas City, and Indianapolis a large advertising concern has begun to sell day and night service, purchasing energy from the local supply companies, and charging the customer for the total cost of the poster-board and lighting. Experiments have been made with flame arcs in Chicago. One 450-watt flame arc has been found more than sufficient for 25 ft. of board. At the corner of Broadway and Thirty-fourth Street in New York City there is a poster board provided with fourteen 55-volt 12 amp. flame arc lamps, burning two in series. The lamps burn from sunset to midnight, and the effect is very striking.

Testing of Meters.—In Massachusetts and Wisconsin, customers of electric light companies may have their meters tested by applying to the Board of Gas and Electric Light Commissioners. The fees are paid by the applicant unless the meter is found to register too fast, when the company pays the fees, and is ordered to correct the meter. Five per cent. variation either way is allowed. In New York, under the old laws, every meter in the city was supposed to be tested. Now, however, meters are tested on application only, 4 per cent. being the maximum variation from the standard allowed. By the provisions of the Canadian Law, a meter must be tested and stamped every five years. Only 3 per cent. variation is permitted.

Metal Filament Lamps.—A statement from the Muncie, Ind., Electric Light Co., covering last year, indicates a remarkable substitution of the tantalum for the carbon lamp in a short time. According to the manager, there are 10,000 tantalum lamps now in use out of a total of 32,000 16-c.p. lamp equivalents connected. Appreciation is further attested by the fact that each lamp was sold at 2s. 6d., and that few converts returned to the old carbon-filament lamp, which they could obtain at about 8d. Over 250,000 tantalum lamps had already been put into service in the United States by September last, and considerably more would be in use had the manufacturers been able to supply the demand more rapidly. On direct current the average life of the tantalum lamp is over 700 hours for the smaller size, and 1,000 hours for the larger size lamp. The life for alternating current appears to be reduced on 25 cycles to about two-thirds, and on 60 cycles to about one-half of the direct-current life. The point in rates, where it is economical to use high-efficiency lamps, can be determined with the aid of the following:—For the same illumination, the Gem graphitised carbon filament saves 20 per cent., the tantalum 33 per cent., and the tungsten 60 per cent. in energy over the 3·1 watt carbon-filament lamp.

Arc-Lighting Progress.—The most interesting and novel feature of arc work is the new Jandus "regenerative" enclosed flame arc just brought out in England (this arc lamp was fully described in Electrical Engineering, Vol. III., p. 299). Returning from a trip to Berlin, Germany, this year, Mr. L. J. Auerbacher stated that practically all the commercial arc lighting in Berlin is accomplished by flame arcs. There are a few open arcs still used, but no enclosed arcs. As to the large practical use of the magnetite arc, the experience at Jackson, Mich., may perhaps be taken as average and typical. Three years ago, when the lamp was introduced, 300 were put up on the streets of that city. There was trouble with spattering from one of the electrodes, but after a solid copper electrode had been used the globe breakage was no greater than with other arcs. The cost of electrodes, including the copper blocks and magnetite sticks, was a little less than the cost of carbons for enclosed arcs, and the lamp burned as long between trimmings. It was found to take 320 watts for 4-ampere lamps, as against 525 for the lamps displaced. Owing to the excellent distribution of the light, print of a given size could be read twice as far away from a magnetite lamp as from a 525-watt carbon arc.

Increase in Power Loads.—There have been some notable examples of sale of electrical energy in bulk during the past year. Thus the New York Edison Co. has had contracts for the supply of several thousand kilowatts for the construction work on the New York Central terminal; Chicago has had a kindred experience with the railroad lines; and Boston has followed suit. The most striking example of this development has been the completion of the electrically-operated, high-pressure water systems in New York and Brooklyn for fire protection. The prevention of the overlapping of the lighting and motor loads has been successfully accomplished at Montreal by the adoption of the Gossler system. At present the Montreal Heat, Light & Power Co. has connected to its system the equivalent of 450,000 16-c.p. lamps, about 37,000 h.p. in motors, and upward of 1,000 appliances for heating, cooking, refrigerating, and so forth. The company serves upward of 13,000 electricity consumers. The company's motor rates are of particular interest in view of the success that has been attained in the broadening of the load curve. Non-peak power users are encouraged by a special concession, as will be seen by the following brief *résumé* of the rates at present in force. The services are classified as follows: (1) Unlimited day service, 10 hours straight, 7 a.m. to 6 p.m. (2) Unlimited day and night service, 24 hours, continuous. (3)

Digitized by Google

Limited day service (off-peak), from 7 a.m. to 6 p.m. throughout the year, except between 4 and 7 p.m. between September 15th and March 15th. (4) Limited day and night service (off-peak), 24 hours per day throughout the year, except between 4 and 7 p.m. between September 15th and March 15th. On the limited day service the reductions given by the company amount to 25 per cent. of the unlimited day rate. The same ratio of difference applies to the unlimited day and night service and the limited or off-peak day and night service. Three systems of charge, equalising one another under certain load factors, are in vogue, as follows:—(1) A straight flat rate per horse-power-year, varying according to the average maximum load as determined by test. (2) A readiness-to-serve charge, based on average maximum demand plus a meter charge per h.p. or kw.-hour, also varying according to demand. (3) A straight meter rate per kilowatt-hour or horse-power-hour, as the customer chooses, likewise varying according to demand.

It has been found that about 40 per cent. of the company's customers can cut off power at the time of peak load without detriment to themselves. Among the loads are 3,500 horse-power in cotton mills, which start at 7 a.m., instead of 8, and which allow half an hour for lunch, stopping work at 4.30. The operatives in many instances prefer to follow these hours and go home early than to begin later and close later. Among these off-peak customers are the various morning and afternoon newspapers, to which the company supplies upward of 400 h.p. Another class of customers is found in brickyards. These require entirely a summer service, and get about 50 per cent. of the regular rates on seven months' operation. These amount to 600 or 700 h.p., the motors being used to drive casting machines, mixers, and conveyers. Other non-peak users are the local water-power company, which uses 1,200 h.p. in pumping drinking water; the Railway Appliance Co., 500 h.p.; various woodyards and cement works. In the woodyards all the cutting is done during two or three hours of each day. From 5,000 to 6,000 h.p. will be used in the cement industry at Montreal this year. The non-peak rates are as yet given only to trustworthy customers consuming relatively large amounts of power. An installation of 20 to 25 h.p. would be about the limit below which the non-peak rate would not as yet be granted. Separate circuits are not run, and the time switch has not yet been applied to any extent, though it is being considered by the company.

Wiring.—The Commonwealth Edison Co., of Chicago, has now been wiring old houses located on its service lines on the instalment-payment plan since last summer. A regular schedule of costs per outlet and per lamp was drawn up for the use of solicitors. At Pueblo, Colorado, the engineer has wired up 1,200 residences, free of charge, in order to get their business. In the case of the majority of small residences in any city it is hopeless to expect that the owners or builders will go to the expense of employing special expert advice on the lighting. Yet it is in these small dwellings that economical and efficient arrangements are most important, both to the consumers and to the central-station company. If the electric lighting arrangements are not efficient, the company will lose this valuable class of business, which in the aggregate is one of the best classes of lighting load a central-station company can have, because of its size, stability, and comparatively good load factor, and because sooner or later it involves electric heating and cooking. But the owner or builder will not appreciate the importance of good design in the lighting, and will not pay for expert advice. It is therefore up to the central station authority, as the most interested party, to step in with such advice.

Prepayment Meters.—Another point that has not yet been very hard pressed is the use of prepayment meters. The prepayment meter appeals to the large class of people used to handling small quantities of money and to spending a little at a time, as they go along. For the central station this meter has the advantage of reducing the cost of collecting bills and keeping accounts. These meters can be adjusted for different rates per kilowatt-hour, so that when installed on the premises of a long-hour consumer he can be given the benefit of one rate. They can also be used for electric cooking circuits, where the customer wants to know his costs. For store window lighting the meters can be used as a time switch. Their cost is now only about 15 per cent. higher than a common meter of the same capacity.

SINGLE-PHASE GENERATORS

A PAPER describing modern developments in single-phase generators was read by Mr. W. L. Waters at the recent convention of the American Institute of Electrical Engineers at Atlantic City. The single-phase alternator has been in commercial use now for 20 years, and it may seem surprising that there should be new developments at this late date. However, single-phase alternators have been used in the past almost exclusively for lighting work, and in units of comparatively small output and low speed. Recently, on account of the adoption of single-phase current for traction work, an important demand has arisen for large high-speed, low-frequency, single-phase generators. It is in the design and manufacture of such units that the engineer has had to overcome new difficulties. In large, high-speed, single-phase generators for 15 and 25 cycles the difficulties met with are due almost entirely to the large pole-pitch and high armature reaction which it is necessary to adopt. A 500-kw., 60-cycle, 72-pole, single-phase generator would have a pole-pitch of about 7 in., while a 6,000-kw., 15-cycle, 2-pole machine would have one of about 120 in. It is easily seen that the design of these will be radically different.

These difficulties in single-phase generators of large pole-pitch are the result of pulsation of the armature reaction, and mechanical stresses on the end-connections of the armature coils. The pulsation of the armature reaction causes hysteresis and eddy-current losses throughout the machine, often resulting in dangerous heating and low efficiency. The mechanical stresses due to the current in the ends of the armature coils result in vibration and distortion of the windings, and often in damage to the insulation or complete destruction of the coils, these stresses being particularly serious in single-phase railway generators, on account of the sudden variations in load and numerous short-circuits to which these machines are subjected. As the effect of the mechanical stresses on the armature coils, and the losses due to the pulsation of armature reaction, practically increase proportionally to the square of the pole-pitch in generators of standard design, it is easily seen why these effects which were negligible in the old single-phase alternators of small pole-pitch have become quite serious in the modern turbine-driven generator. The seriousness of these difficulties when they were first met with was so great that even within the last two years responsible engineers have stated it was impossible to build satisfactory low-frequency, high-speed, single-phase generators of large capacity, and it is only by careful study and experimenting that the modern machine of this type has been developed.

Losses Due to Pulsation of Armature Reaction.—In a polyphase generator the armature current produces a magnetic flux which rotates synchronously with the field magnet. This magnetic flux, being of practically constant magnitude, causes very little loss in the iron of the magnetic circuit. On the other hand, the armature current in a single-phase generator produces a pulsating magnetic flux which is stationary in space. It is easily seen that this pulsating flux will cause hysteresis and eddy-current losses throughout the whole magnetic circuit. The exact effect of the armature reaction flux on the rotating magnets depends, of course, on the relative phase of the armature current and electromotive force—that is, on the power-factor of the load on the generator. When the power-factor is unity and the armature current is in phase with the electromotive force, the armature reaction flux is a cross-magnetisation; when the power-factor is zero and the armature current is 90° out of phase with the electromotive force, the armature reaction flux is a demagnetisation. In the special case in which the rotating field magnet is cylindrical, without projecting poles, the effect of the armature reaction flux on the magnets is, of course, more nearly independent of the power-factor of the armature current. But in any case this flux is a pulsating one, and there are important losses in the field magnets, due to their rotation through this pulsating cross-flux or demagnetisation flux.

An estimate of the combined losses in the armature and field magnets due to the pulsating armature reaction can be obtained in a number of ways. We can measure the increase of the power required to rotate the field magnets due to normal root-mean square current in the armature coils, with: (1) Direct current in the armature; (2) alternating current of synchronous frequency in the armature; (3) armature short-circuited and field excited. Or with the magnets stationary we can: (4) Send normal frequency alternating current through the armature and measure the losses by a wattmeter.

These methods must all be regarded as convenient tests which

Digitized by Google

are found by experience to give a good indication of the magnitude of the losses. Method (4) has the additional advantage that we can vary the relative position of the armature reaction flux and the pole faces, and thus investigate the variation of the losses in a single-phase generator with the power-factor of the load.

The only exact methods of measuring the losses are: (1) As unknown losses in a motor-generator-method efficiency test, or (2) from a comparison of the temperature rise obtained on full load with that obtained with known losses. Unfortunately, both of these tests are difficult to make accurately, especially on a large machine, and probably in practice they do not give results which are any more accurate than the other methods. So at the present time we have to acknowledge that though we know a great deal about the relative values of the losses under various conditions, our knowledge of their absolute values are only approximate.

Pole-face dampers.—Losses caused by a pulsating flux in the magnetic circuits are due to: Hysteresis and eddy currents. And the relative magnitudes of the two depend on the amount of solid metal in the path of the flux. If the whole magnetic circuit is laminated, then the losses are practically all due to hysteresis. On the other hand, if we have solid cast-steel poles there will be eddy currents in these poles which will partly choke back the pulsation of the flux and the hysteresis loss will be reduced. But in this case there will be eddy-current losses in addition to the hysteresis, and the way in which the total loss is changed will depend on the proportions and design of the magnetic circuit. If we place a heavy copper damper in the path of the pulsating flux, this will provide a low-resistance path for the eddy currents, and the pulsating flux, and consequent hysteresis loss, will be reduced practically to zero, while on account of the low resistance of the damper circuit the eddy loss will not be appreciable. The way in which the losses and the pulsating flux vary according to the presence of eddy currents can be determined for any particular design by changing the thickness of the laminations, or changing to solid poles or dampers. It is usually found that the losses are greatest with heavy laminations or solid poles; that they are less for thin laminations, and practically zero when heavy low-resistance dampers are used either with solid or laminated poles.

The pulsation of the armature reaction flux can be damped out by covering the pole faces with a ⅜-in. copper plate. In practice, a copper damper usually takes a form similar to the squirrel-cage secondary of an induction motor. Heavy copper bars are dovetailed into the pole faces, and short-circuited at the ends by copper rings or discs.

The question of losses due to the pulsating armature reaction in a single-phase generator may be considered in another and possibly a simpler way. The single-phase pulsating field is equivalent to, and produces the same effect as, two rotating fields each of half its maximum value, one rotating at the same speed and in the same direction as the generator field magnet, and the other rotating at the same speed but in the opposite direction. The flux rotating synchronously with the field magnet, being constant in magnitude, causes very little loss. The flux rotating in the reverse direction causes losses throughout the whole magnetic circuit due to hysteresis and eddies. If we have a squirrel-cage damper enclosing the field magnets, this damper system acts in regard to this reverse rotating flux in the same way as the short-circuited secondary of an induction motor or transformer, a current is induced in the damper which produces a field that neutralises the rotating flux. The eddy and hysteresis loss in the iron of the magnetic circuit which would be caused by this rotating flux is thus eliminated, and the only loss is that due to the current circulating in the damper. If we make the conductors forming the squirrel cage of sufficiently low resistance, this damper loss becomes negligible, with the result that the entire loss due to the pulsating armature reaction of the single-phase generator is practically eliminated.

To show how serious this matter of losses becomes in two-pole single-phase machines without dampers, the table in the next column is given, showing the losses and full-load temperature rises on three turbo-generators, both with and without dampers.

It will be seen that in these three machines, operating single-phase, there is due to the pulsating flux an average loss of 3·5 per cent. and an average temperature rise of 125° C., without dampers; with dampers the average loss is 0·5 per cent. and the temperature rise 30° C. Figures are given only on comparatively small machines on account of the difficulty of measuring losses on large machines. But tests on larger generators up to 6,000-kw. capacity show that the improvement due to heavy copper dampers is even more striking in large machines than it is in small. So far as experience goes at the present time, it may be said that the use of such dampers is the complete solution of the difficulties due to pulsating armature reaction met with in large, low-frequency, two-pole, single-phase generators.

Mechanical stresses on armature coils.—That it was necessary mechanically to brace the end-connections of the armature coils on a direct-current machine subjected to sudden loads and short-circuits has been known for many years. But until quite recently additional supports for alternator armature coils were seldom provided. The reason for this was that as the continuous short-circuit current of an alternator is only about two or three times normal, it was not considered that the mechanical stresses on the ends of the small pole-pitch coils generally in use were sufficiently great to cause any trouble. Only during the last few years has it been demonstrated by experience that coil supports on large pole-pitch alternators are not only advisable but necessary, and that on account of the numerous short-circuits, they are particularly necessary on single-phase machines operating on traction circuits.

Two-pole, 25-cycle, single-phase generators. Same current per armature conductor one- and three-phase under all conditions and all losses in per cent. of single-phase rating.

Size.	Type field.	Three phase.		Single phase.			
		Without dampers.		Without dampers.		With dampers.	
		Loss	Temperature.	Loss	temp.	Loss	temp.
750 kw.	Solid	0·53	27°C.	3·75	95°C.	0·8	24°C.
1000 kw.	Solid	0·3	31°C.	3 0	122°C.	0·5	37°C.
1000 kw.	Laminated	0·2	19°C.	3·8	150°C.	0·3	18°C.

When an alternator is suddenly short-circuited, the first rush of current is limited only by the self-induction in circuit. In the case of an alternator of very low self-induction, this first rush of current on sudden short-circuit will be 15 or 20 times normal full-load current. As the mechanical stress on the end-connections varies as the square of the current, this means that the stress on the armature coils is 200 to 400 times normal. A 6,000-kw., 2-pole, 25-cycle, single-phase generator will have a pole pitch of about 100 in., and the length of the end-connection at one end of one armature coil will be about 180 in. We find that the mechanical stresses on the end-connections at one end of one armature coil of this machine on a sudden short-circuit is something like five tons; and we usually find that on low-frequency high-speed generators of large capacity the mechanical stresses on the end-connections at one end of one armature coil on sudden short-circuits are from 2 to 10 tons. When we consider that this comes as a sudden mechanical shock on the winding, we can realise the kind of coil supports that are required, and can understand the disastrous results sometimes obtained on short-circuits, when such supports are omitted.

We can see from these stresses that coil supports must be of metal of heavy cross-section. The objections to metal are, of course, those of insulation, but though coil supports of wood, porcelain, and similar insulating materials have been tried, it is easily understood that they have proved unsatisfactory on machines of large pole-pitch.

The two main difficulties met with in large low-frequency, high-speed, single-phase generators, which have been described above, can at the present time be regarded as having been successfully overcome. The use of heavy copper dampers on the pole faces and heavy bronze coil supports applied to the ends of the armature coils in such a way as to take directly the mechanical stresses which develop on short circuits, have now made such machines a practical success. Like every other new type of electrical machinery, the large turbine-driven, single-phase generator has had to go through a period of development, but at the present time it may be said that such generators for 15 and 25 cycle, and in units of 5,000 to 10,000 kw. capacity can be, and are, built with the same success as that obtained on standard slow-speed polyphase generators.

The German Patent Laws.—The revision of the German patent laws will be undertaken shortly. Definite proposals have already been made by certain industrial societies, and the Verband Deutscher Elektrotechniker has appointed a commission consisting of ten members, to consider the matter in the interests of the electrical industry.

STREET LIGHTING IN CAPE TOWN

THE current issue of the Institution of Electrical Engineers contains an abstract of a Paper on electric street lighting by Mr. W. F. Long (Cape Town Local Section), which includes the following account of street lighting in Cape Town.

There is not a great deal of street arc lighting in Cape Town, but, with the exception of Darling Street, it is controlled either from the central power station or the accumulator station. A series of flame arc lamps has recently been installed in the Dock Road, and in view of the entire absence of flame lamps in Cape Town until these were installed, the author dealt somewhat fully with this installation. The lamps used are the now well-known Oriflamme type, manufactured by Messrs. Oliver & Co., of Woolwich, in which a magazine is provided by means of which the lamps are supplied with eight pairs of carbons, the second pair being automatically brought into action when the first pair are consumed, likewise the third pair when the second are consumed, and so on; the lamp is thus only trimmed after thirty-five hours' burning.

An inspection of the lamp will show that the feeding of the carbons from the magazine is accomplished by means of an endless chain revolved by a pawl and ratchet, the former being actuated by an electromagnet. This electromagnet is operated by a shunt coil, which is momentarily put in series with the shunt winding on the main coil of the lamp when it is time for the feed to take place. A novel feature in connection with this feeding coil is the switch, which, it will be noted, is an evacuated tube containing mercury and pivoted at its centre so as to allow of a rocking movement. On the arc reaching the position where feeding should take place, the tube is tilted sufficiently to allow the mercury to flow the whole length of the tube, to the ends of which are connected the feeding coil. The magnet then lifts, and, as before mentioned, works the pawl and ratchet motion, the lifting of the magnet itself rocking the switch back to the off position.

In spite of the fact that these switches are continually opening and closing the circuit, they last quite a long time, but eventually the glass is cracked through the continual mercury hammer, when, of course, the switch soon becomes useless, due to the loss of vacuum.

An unusual feature of the lamp is the low voltage required, the pressure across the terminals being only 34 volts, which allows of 11 lamps being burned in series across 440 volts. The normal current is 9 amperes; each lamp therefore consumes 306 watts, and the mean candle-power in the lower hemisphere is stated to be 1,300. As a matter of fact, it is found in Cape Town that these lamps give much better results with 10 amperes. The energy consumed on the circuit, including line resistance, is therefore 4,400 watts, giving a total candle-power of 14,300, and costing at the current price for street lighting in Cape Town 0·0016d. per candle-power per hour, including all labour and materials for trimming and general maintenance, together with interest charges on the capital expenditure in providing and installing the lamps. The lamps are placed in Hyde Park carriers on tapered steel poles placed in the centre of the roadway, the whole of the wiring being carried out by means of No. 4 S.W.G. bare wire carried on insulators attached to the poles.

Owing to the exceptionally long spans, 210 ft., and to the fact that at the time heavier poles could not be obtained for the ends of the line, it was not possible to run two wires of the above section on the lamp poles themselves; the return wire is therefore attached to the poles at the side of the road carrying the ordinary three-wire distribution system. In addition to the flame lamps, each pole also carries a double bracket fixed about 12 ft. 7 in. from the surface of the road, each bracket containing two 110-volt 25-c.p. tantalum lamps in series, which are, of course, wired on a separate circuit. The overhead wires in this case being No. 12 S.W.G. are attached by means of insulators to the sides of the Hyde Park carriers, so that the only wire causing a shadow with the arcs is the one No. 4, and this is said to be hardly noticeable. Both the arc and tantalum circuits are controlled direct from the generating station.

Turning now to the question of side-street lighting. Some twelve months ago a trial was made with 25-c.p. 110-volt tantalum lamps on an extension to the street-lighting system, and as the illumination required per pole was not to exceed 25 c.p., these lamps were installed by running series overhead wires between poles. The lamps proving very satisfactory and being seldom reported as not lighted, steps were taken to change the majority of the carbon filament street lamps for tantalums, so that now quite 80 per cent. of the street lighting is carried out in this manner. The 25-c.p. 110-volt tantalum lamps take on an average 0·2 of an ampere; a No. 14 S.W.G. bronze wire has ample carrying capacity as the series wire, even if, as in some cases, the lamps are a considerable distance apart. As an instance of the saving that can be effected by this lamp, continues Mr. Long, I should state that the cost of street lighting in Cape Town has been reduced this year by 33⅓ per cent., although some 300 additional side-street lamps and about 20 arc lamps have been erected, whereas the charge per unit for energy consumed for street lighting purposes has only been reduced by 12 per cent. The only personal experience he has had with Osram lamps for street lighting up to now was with two samples which were placed on a street-lighting circuit. These lamps were marked 110 volts 32 Hefner candle-power, and gave an initial candle-power on the photometer of 27 English candles with a consumption of 36·7 watts, or 1·2 watts per candle. A second test was made after 374 hours, when the figures were 25·1 c.p. at 1·5 watts per candle. A third test after 504 hours gave 23·5 c.p. at 1·6 watts per candle.

The Cape Town City Council has been successful in obtaining the street lighting of Woodstock in competition with the local gas company. The work in connection with this scheme is now in course of construction. The distributing system will be entirely overhead and carried out on a three-wire system similar to Cape Town, with 440 volts across the outers. The lamps to be erected comprise 300 in number, and will consist of two 110-volt 32-c.p. Hefner, Osram lamps, in series in one fitting. The energy required will be transmitted from the power station in Cape Town to the boundary of Woodstock and Cape Town by extending an existing 0·4 sq. in. concentric feeder; the feeder being also used for the supply of energy to private consumers until such time as the loads warrant the use of a sub-station. The overhead distributing system entails the use of some 300 poles and 35 miles of bare overhead wires.

The following particulars are useful as a guide to the possibilities of street lighting locally by means of metallic filament lamps as against incandescent gas. One suburban municipality is paying to-day £7 per 60-c.p. incandescent gas lamp per annum for 2,000 hours' burning. A recent quotation to another suburban municipality was £6 10s. per 55-c.p. incandescent gas lamp per annum for 2,000 hours' burning. The average various tests of gas mantles made in recent years prove that they take 0·1 cub. ft. of gas per candle-power per hour, which information, together with the above, gives the following comparative table for gas and metallic filament lamps :—

System of Lighting.	District.	Candle Power.	Charge per Lamp per Annum.	Hours Burning.	Cost per C.P. per Hour.	Energy Consumed. Gas Cub. Ft. Electricity Units.	Cost of Energy. Gas per 1,000 Cub. Ft. Electricity per Unit.
			£ s. d.		d.		s. d.
Incandescent ...	Sea Point ...	60	7 0 0	2,000	0·0140	12,000	11 8
Incandescent ...	Woodstock..	55	6 10 0	2,000	0·0141	11,000	11 9
Tantalum Electric	Cape Town..	25	2 18 2	3,000	0·0093	127	5½
Osram Electric	Woodstock..	50	5 10 0	2,000	0·0132	125	10½

The column "Cost of Energy," of course, includes both interest charges and maintenance. The Woodstock figure of 10½d. per unit is high, owing to the fact that the whole of the capital expenditure entailed has to be repaid in five years.

Jubilee of the First Atlantic Cable.—Mr. Charles Bright, F.R.S.E., who is the son of the late Sir Charles Tilston Bright, in reference to our editorial note on the jubilee of laying the first Atlantic cable, calls our attention to the fact that the first public news message was transmitted on August 17th, 1858—fifty years ago last Monday. Mr. Bright has also sent us a reprint of a lecture before the Royal United Service Institution last year, which contains a facsimile production of the Atlantic Telegraph Co.'s form with this message transcribed upon it. He also mentions that the first cable from Dover to Calais was an insulated core with leaden weights attached, and that Mr. C. J. Wollaston was the engineer who laid this for the Bretts. Sir Charles Bright was the first to lay a cable in deep water in 1852 from England to Ireland, and he was only twenty-one years of age at the time.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Aug. 13th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

1907 Patents

8,851. **Variable Speed Polyphase Induction Motor.** H. A. Mavor and Mavor & Coulson, Ltd. A polyphase induction motor, consisting essentially of two motor systems. The primary member of the main motor (usually stationary, and termed the "stator"), is capable of rotating in either direction, and is mechanically connected to the rotor or secondary member of the other or auxiliary motor. The relative speed of the primary and the secondary member of the main motor must always be the same, so that by rotating the primary member the rotor can be run above or below the synchronous speed. The speed of the rotor of the auxiliary motor may be varied by altering the number of its effective poles. The main motor may be constructed concentrically with or axially to the auxiliary motor, the primary member of which is stationary. Five claims, six figures.

16,485. **Limit Switch.** R. Lenner. This consists of an electro-magnet with a series winding, which lifts an armature when the current attains to a certain value. This inserts a resistance in the main circuit, so that the current is reduced to a very small amount. If the load resistance is increased, the resistance is short-circuited, and the load has the normal voltage. A winding on the electro-magnet, in series with the resistance, prevents the armature falling when the main circuit is broken. If the current coil of an ordinary wattmeter is substituted for the resistance, the current consumption is measured immediately it exceeds the contract value, but the voltage at the load is not affected. Six claims, four figures.

23,710. **Ventilation of Electrical Machinery.** H. G. Reist. A method of construction of the laminated cores of electrical machines, which consists in providing axial passages in the cores of both stator and rotor, parallel to the shaft, as well as the usual ducts at right angles to the shaft. One end of the machine is closed, and a fan attached to the rotor at the other end drives air through the axial passages in the rotor and back through the stator. Four claims, four figures.

26,134. **Field Systems for Turbo-alternators.** Siemens Brothers' Dynamo Works and J. Birrer. In alternators with rotating salient poles and running at high speeds, special means have to be provided to ensure both mechanical strength and good ventilation of the field winding. According to the present invention, the field winding is subdivided and supported against the action of centrifugal force by lateral projections of the poles, which form slots for the windings. The bunches of conductors are secured in the slots by dovetailed wedges of fibre. Three claims, two figures.

27,260. **Alternating Current Machine.** Dr. R. Goldschmidt. An alternating current generator, the operation of which is due to the peculiar reaction of a single-phase rotor winding, short-circuited on itself, and rotating in a stationary field. Continuous current is supplied to the stator field winding, which may be part of the generating winding. The rotor winding is short-circuited. An alternating current of double the frequency of the rotor current is generated in the stator winding. To prevent alternating currents from circulating in the exciting circuit, a choking coil is inserted in that circuit. If the exciting winding is supplied with alternating current, the machine acts as a frequency converter. Eight claims, one figure.

1908 Patents

3,583. **Wireless Telephony.** G. Siebt. In one method of effecting wireless telephony, the variations in intensity of the rapid frequency oscillations are caused by variations of the current that feeds the arc lamp, while these variations are produced by superimposing the microphone current upon the main current. The variations of the microphone current are, however, then only very weak, because this current must traverse the arc, the choking coils, and all the resistances in the circuit. An improvement is effected, according to this invention, by shunting the arc with a resistance or a capacity. This gives an easier path for the high-frequency microphone current. Six claims, two figures.

8,107. **Manufacture of an Insulating Material from Peat.** H. Branco and G. Gumpert. A process for producing an insulating material from peat without the addition of any binding media. The peat is treated in a moist condition, so that the fibres are entangled, and all foreign substances, such as sand or particles of wood, are removed. The product is then subjected to the action of dry superheated steam for two or three hours, after which it is moulded under high pressure. Chemical substances may be added to render the material fireproof. One claim.

9,497. **Elastic Supports for Metal Filaments.** W. Schäffer. On account of the contraction and expansion of metal filaments, it is necessary to make the supporting hooks elastic. The fine wires necessary for these were easily damaged when there were several to be inserted. According to this invention, comparatively stout wire (say 0·4 mm. diam.) is used, and is flattened out for part of its length to give the necessary flexibility. One claim, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

9,950, Mavor & Mavor & Coulson, Ltd. Control of alternating current generators and motors.
12,008, Saunders, Davis & Griffiths. Railway signalling apparatus.
15,016, Tracey. Apparatus for checking code telegraphy.
17,332, Mladek, Mladek & Samal. Electric power transmission.
17,463, Postans. Magneto-electrical ignition devices for internal combustion engines.
17,475, British Thomson-Houston Co., Wedmore & Hamlyn. Circuit-breakers.
17,490, Fennel & Perry. Thermo-electric generators.
18,444, Haigh. Marine electrically-controlled steering gear.
19,492, Siemens Bros. & Co. & Ferreira. Combined semaphores and indicators for railway signalling.
19,493, Siemens Bros. & Co. & Ferreira. Interlocking signal and points levers.
20,397, British Thomson-Houston Co. (*General Electric Co.*). Rheostatic controlling switches.
20,859, Beutel. Automatic signalling between trains.
22,572, Cummins. Sanding gear for tramway vehicles.
24,505, Scheffler & Schumacher. Screw clamp for connecting electric wires.
25,478, Electric & Ordnance Accessories Co. & Hall. Electric fuse holders.
25,605, Grosse. Insulating floor covering.
25,864, Feather. Device for supporting the trolley wires of electric tramways.
27,222, British Thomson-Houston Co. (*General Electric Co.*). Protective devices for electrical systems.
28,494, Boon & Mellaerts. System for preventing the falling of electric tramway wires.

1908 Patents

1,239, Hoffman. Suspending devices for electric conductors.
3,096, British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*). Control of alternating-current motors of the commutator type.
3,648, Böhmer. Method of automatically controlling the switches of hoists and elevators.
5,390, Struble. Lightning arresters.
5,489, Sykes, Sykes & Cooke. Electrical control of railway traffic.
6,162, Soc. d'Electricité Nilmelior. Contact-breaker mechanism for ignition apparatus of explosion motors.
8,874, Levy & Mehlhose. Electric ventilator.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

11,517, Siemens-Schuckert Werke Ges. Continuous-current machines.
15,664, Allegemeine Elektricitäts-Ges. Protective devices for electrical apparatus.
15,746, Lafitte. Long-distance lighting.
15,854, Compagnie Française de l'Ozone. Purification of water by ozone.
15,875, Moonen. Sparking-plugs for explosion motors.

Expiring Patents

No patents of electrical interest expire during the current week.

THE WORKS AND WORK OF MESSRS. ERNEST SCOTT AND MOUNTAIN, LIMITED

IT would probably be impossible for such a firm as Messrs. Ernest Scott & Mountain to have had its origin and flourished in any other district than the Northumbrian and Durham coal area, unless, possibly, in South Wales. This is because this firm is an instance of specialisation upon a subject, and at a time which was bound to yield satisfactory results if the problems presented were dealt with in a sufficiently pioneering manner. As early as 1890 Mr. W. C. Mountain recognised that the application of electricity to collieries for the purpose of pumping, hauling, and coal-cutting had a considerable future, and in that year the firm secured its first mining contract, an electric pumping installation for the Cowpen Coal Co., at Blyth. At this time the firm was located at its old quarters, The Close, Newcastle, near to the new works of the Newcastle and District Lighting Co., Ltd., and when electrical work was first undertaken the firm employed only 50 to 60 men in the engineering department.

Orders for mining plant began to assume larger sizes. Underground haulage and coal-cutting were tackled in their earliest days by this enterprising firm. Their earliest coal-cutter, of the disc type, was supplied to Mr. G. A. Mitchell, of Glasgow, in 1893. They were also one of the first firms in this country to introduce three-phase colliery plant, the Tredegar Coal & Iron Co. being the earliest colliery fitted up in this way by the firm. Owing to this influx of work the firm had to migrate to larger works on the Gateshead site, and then purchased in 1904 the old works of Messrs. Black, Hawthorn & Co. Bearing in mind the special nature of Messrs. Scott & Mountain's business, it is interesting to note a few points concerning the arrangement and equipment of the works.

The plan of the works, which is shown in Fig. 1, indicates the general arrangement. Full-gauge rails run throughout the works as shown, connected with the North Eastern Railway siding. The disposition of the various shops is such that the work can be handled in a consecutive manner without undue carriage. Inspection of the arrangement of the various machines in the shop confirms this impression. For example, in the small machine shop the slotting and milling machines are all kept at one side of the bay. Down the centre, leaving an alley-way on each side, is a double row of high-speed light lathes for iron and steel works, while all brass turning, such as plungers for three-throw pumps, is kept to special lathes standing on the other side of the bay. Notice may also be taken of the fact that in the erecting shops the driving engines and the dynamos, pumps, or whatever else is to be driven, move forward in parallel lines to the test-bed, so that the complete job can be rendered and assembled in a natural manner. Views of several shops are given in the accompanying illustrations.

In going through the shops one notices several large tools which the engine-work of the firm necessitates. One of these is a forty-foot gap lathe suitable for either chuck or centre work, another being a planing machine to take work 20 ft. long by 6 ft. 6 in. high by 8 ft. wide, and a third a 20 ft. vertical lathe. A strong feature is made of vertical lathes and boring mills, enabling engine flywheels, end covers for centrifugal pumps, and similar work to be quickly negotiated. The factory is, however, well equipped with lighter tools for speeding up the rate of work in the shops. At the time of our visit we noticed a lathe attachment consisting of a motor-driven emery wheel engaged in truing up the core of a three-phase rotor; while special machines, both horizontal and vertical, are installed for slotting out shaft key-ways and making the necessary cut on commutator bars for the reception of connectors to the windings. In particular, a special machine by Dickinson & Keighley for milling key-ways should be mentioned for its quick and accurate action. In the erecting bay, besides the usual complement of wall drillers and a special face-plate built into the floor for building up large cores and commutators, very extensive use is made of compressed-air portable tools for chipping and drilling. In order to facilitate the moving of machine parts from one position to another, a crane of 5 tons' capacity serves the light machine shop, the erecting shop possessing three 15-ton overhead electric cranes; the electric and brass shop, in which the armatures, field magnets, small commutators, and other electrical details are made, has a 5-ton electric and a 2-ton hand crane; while the foundry has a 15-ton and a 5-ton electric crane in the main bay, together with an air-driven telfer in the brass foundry. A pressure of 100 volts direct current is maintained for the electric cranes, this being obtained by a belt-driven motor-generator operating from a 500-volt direct-current supply. In order to guard against the sudden fluctuations of load caused by the cranes, a compounding coil is placed on the dynamo field, while the motor is furnished with commutating poles. The air-compressor plant is driven electrically, about 40 h.p. being absorbed in supplying air at 80 lb. pressure for portable tools.

The testing department, which has already been mentioned, is very completely equipped for dealing with the large variety of mining machinery turned out by the firm. A speciality is, of course, the centrifugal pumps, with their attendant drive, either steam or electric. To

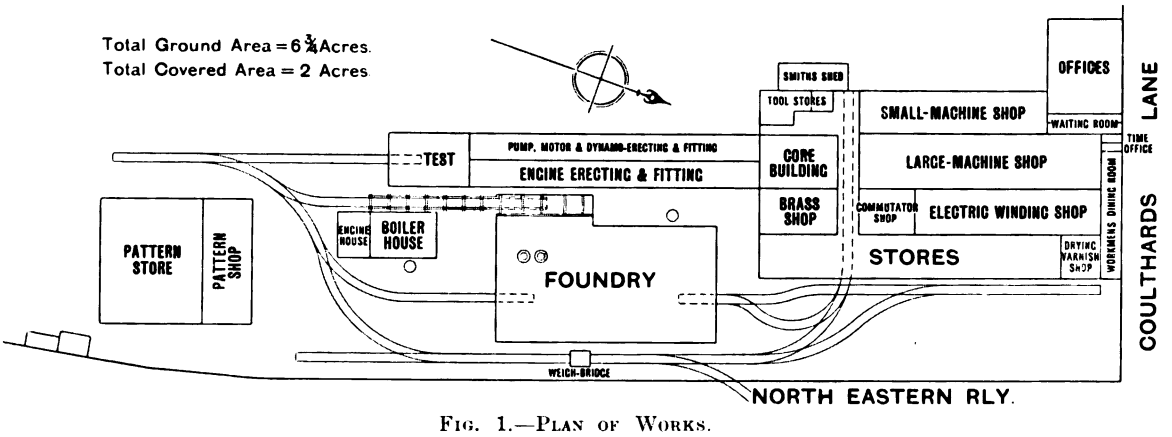

FIG. 1.—PLAN OF WORKS.

Digitized by Google

test the output of these pumps a special tank is provided equipped with special calibrations and means for obtaining any virtual head of water on the pumps. Electric motors of the direct-current type are, if in duplicate, tested on the Hopkinson system, but otherwise they are connected to special dynamos, whose losses are known and whose output is absorbed in tanks. In addition to this, a motor of the three-bearing type giving an output of 250 effective h.p. is used for testing purposes, and for alternating colliery plant a motor is belt-geared to a special generator having a periodicity of fifty, this being the periodicity found by Messrs. Scott & Mountain to be usually adopted in colliery practice. This special set is necessary from the fact that the alternating current supply of the mains passing the works has 40 periods—a somewhat unusual frequency. Latterly a supply of three-phase current has been taken for testing purposes from the County of Durham Electrical Power Distribution Co., Ltd., who have built a static transformer sub-station on the premises equipped with two Westinghouse oil-cooled transformers of 500 kw. capacity operating at 6,000 volts, and having arrangements whereby pressures of 2,000, 3,000, 4,000, or 5,000 can be tapped off. The low-tension board carries one main panel equipped with ammeter and voltmeter, a Frahm frequency meter, relays for circuit-breaking on two out of three phases, and an oil-break main switch. From this four panels are arranged to feed as many different sections of the test-bed, although at present one section is found to be all that is necessary. Although the distribution side of the three-phase supply is under the control of the factory, the incoming side of the transformer house is kept strictly under lock and key, and is only accessible to officers of the Distribution Co. At the back of the board above described is a room set apart for the tanks or vats for load testing. These consist of the usual barrels with movable electrodes operated by ropes and counterweights, having a capacity of 200 amperes at 500 volts. A larger set of tanks is capable of taking loads up to 600 amperes.

The works were originally laid down before the three-phase supply was available; a large amount of direct-current power at 500 volts is therefore taken from the Gateshead station of the County of Durham Electrical Power Distribution Co., Ltd., for lighting and power. This is principally carried through the works in insulated cables mounted on porcelain insulators, and feeds motors of 10 to 50 h.p. through starting switches of either the metallic or liquid type. The latter variety is a speciality of the firm, being much used by them in colliery practice. Group-driving of the machines is resorted to in most instances, the third wire being very rarely used except for lighting purposes, so that there are no balancing difficulties. The number of motors installed for shop purposes totals 42, their aggregate horse-power being 400, including an air-blast motor for a Roots blower in the foundry. Besides 72 arc lamps, each of 1,000 nominal candle-power for general shop lighting, there is a large quantity of incandescent local lighting on special tools and in the offices. A small boiler plant is maintained for the purpose of steam testing, but the works, as a whole, present a fine example of electric drive.

Fig. 2.—Views of Various Shops in the Works of Messrs. Ernest Scott & Mountain.

Owing to the engineering strike, which was in progress during our visit, the full capacity of the works could not be gauged. We noticed, however, some very interesting examples which serve as an indication of the class of business which the firm is handling. In the electrical shop were the component parts of a complete line of interpole motors which Messrs. Scott & Mountain are now manufacturing. In the small turning shops pedestals for three-throw pumps were being machined for stock. Girder-type pumps of a particularly light and rigid character were being assembled for lifts up to 800 ft., variable demand; while vertical three-stage centrifugals for high lifts and constant demands were also being made. An interesting example was a vertical sinking pump equipped with a three-phase squirrel-cage motor, which was just being finished for the Hamsterley Coal Company. There were various haulage gears in the course of construction arranged for rope drive, as, for example, a large machine which had been recently supplied to the Birtley

Digitized by Google

Iron Co. Engine work was also in progress, a speciality being made of central-valve compound engines, a small vertical high-speed engine for the Olympia Exhibition in London being on the test-bed at the time of our visit. On the electrical side, besides a certain amount of repair work, a 600-volt three-phase generator for Newbegin Colliery was nearing completion, while hand-winding was proceeding in a 2,500-volt 50-cycle three-phase generator for the Coltness Iron Co., measuring 160 in. by 12 in. over the core. An interesting piece of work was a special starting switch for operating a 350 h.p. 500-volt direct-current motor installed for haulage purposes at the Birtley Collieries at any required slow speed for any length of time. Some views of the works are shown in Fig. 2.

The present state of the works of Messrs. Ernest Scott & Mountain affords a valuable comment on the alleged desperation of manufacturers at the prolongation of the engineering strike. To judge from the healthy appearance of operations at this factory, disorganisation appears to be limited to the ranks of the man who will not work.

ELECTRICAL SCIENCE

British and American

Radium Emanation.—The amount of radium emanation which can be obtained from one gram of radium in equilibrium can be calculated when the rate of production of emanation per second and the radioactive constant of the emanation are known. The number of α particles expelled per second from a gram of radium has been accurately determined, and, assuming that the expulsion of a single α particle corresponds to the disintegration of a molecule of radium with the formation of a molecule of emanation, the rate at which the latter is produced is easily determined. The result is that a gram of radium in equilibrium contains 0·57 c.mm. of emanation. Ramsay and Soddy, and later Ramsay and Cameron, measured directly the volume of the emanation, and concluded that it was about 7·07 c.mm., which is of quite a different order from the calculated volume. If these experimental values are correct, they would indicate that much of the radioactive data and of the theory on which the calculations are based is seriously in error. E. Rutherford, using a preparation of radium containing about 250 milligrams of radium, has carried out an elaborate series of experiments in order to purify the emanation and to determine its volume. Some of these experiments are described in the *Phil. Mag.* for August. Two methods were used to obtain the emanation – one by heating the radium salt, the other by dissolving it in water and evaporating. The emanation was purified by condensing it with liquid air, when gases such as hydrogen, oxygen, and helium, which are not liquefied, could be removed. The greatest difficulty was experienced in getting rid of CO_2; it was found necessary to allow the emanation, after purification from other gases, to remain for many hours in contact with caustic potash. The purity was tested by the spectroscope, and the volume measured in a capillary tube 0·58 mm. diameter. When the emanation is first collected in the capillary tube its volume gradually diminishes; thus in one experiment it decreased from 1·05 c.mm. to 0·58 c.mm. The reason for this contraction is not known. Taking the contracted volumes in each case, the mean of three experiments gives 0·61 c.mm. per gram of radium, a number which is in reasonable agreement with the calculated volume. Rutherford concludes that the emanation used by Ramsay and Cameron could not have been pure.

Continental

Pure Iron.—H. Kreusler has gone to considerable trouble to obtain really pure iron, and he describes some interesting results in the *Verhandlungen*, No. 9, of the German Physical Society. He precipitated iron oxalate from iron-ammonium sulphate. The oxalate was ignited, and the resulting oxide reduced by pure hydrogen. The spongy iron was dissolved in hydrochloric acid, again precipitated with oxalic acid, and the process repeated. Great difficulty was experienced in getting rid of sulphur. He finally succeeded by forming an arc between electrodes of purified iron and letting drops of iron fall into mercury. The iron thus treated looks exactly like platinum. It is exceedingly ductile and malleable, is not attacked by hydrochloric acid, but rapidly dissolved in nitric acid. Compared with the best dynamo sheet iron, it shows a much greater hysteresis. This proves that hysteresis is not mainly due to impurities in the iron, as has been sometimes supposed. As regards conductivity, it is markedly superior to any yet found in iron. Lorenz's highest value is 9·685 at 0°. The author's is 10·61. The author enclosed wires of the pure iron in glow lamps and heated them to a yellow glow. They did not give off perceptible amounts of gas. Contrary to the behaviour of ordinary iron, the resistance was not affected by the treatment.

Electrocapillarity.—In the course of an elaborate research, described in an essay covering over a hundred pages of the *Annales de Chimie et de Physique* for August, G. Reboul deals with the electric phenomena at the surface of a metal immersed in a gas. There is, he says, an electrified double layer at the surface of a metal in a gas, just as in a liquid, and electrocapillary and thermoelectric phenomena exist equally in both cases. In Lippmann's capillary voltmeter, the liquid may be replaced by an ionised gas. Even the water-dropping electrometer may be replaced by an instrument in which an ionised gas escapes from a metallic orifice. The emission of ions by metals is, as already known, greatly influenced by the temperature. The author gives a fascinating theory of these actions. The double layer is the result of a dynamic equilibrium between positive ions, electrons, and neutral charges, which is governed by the law of Guldberg and Waage. Any modification of this equilibrium leads to the emission or absorption of ions of either sign. The author works out a formula for the emission of negative ions which is in accordance with Richardson's observations at low pressures.

Monotelephonic Circuits.—E. Mercadier, who proved some time ago that by means of electric tuning forks and suitably tuned telephones half a dozen simultaneous messages could be sent over the same wire, reports an extension of this system in the *Comptes Rendus* for August 10th. It is now possible to transmit messages from Paris to Marseilles from a dozen instruments over the same wire, and to record them at the other end by as many Morse or Hughes recorders. The system is particularly elegant. A small lever presses lightly against the tuned telephone disc. When the disc vibrates, the lever is repelled, and does not resume lasting contact until the vibration has ceased. If the lever works a direct-current relay, the alternate current transmitted is practically converted into a direct current suitable for a Morse recorder. The energy consumed is surprisingly small, and six accumulators suffice for working the whole apparatus, the line resistance being 1 ohm per kilometre.

Degradation of Copper.—Madame Curie and Miss Gleditsch, in the *Comptes Rendus* for August 10th, announced their having failed to confirm the conversion of copper into lithium under radium emanation, announced by Ramsay and Cameron.

The Journal.—The August issue of the Journal of the Institution of Electrical Engineers (No. 191, vol. 41) contains the following papers and discussions thereon:—"New Alternate-current Instruments," by Dr. W. E. Sumpner and J. W. Record; "High-speed Electrical Machinery," by G. Stoney and A. H. Law; "Electricity Supply Prospects as Affected by Metallic Filament Lamps and Electric Heating," by H. W. Handcock and A. H. Dykes; "Electrolytic Corrosion," by Prof. W. W. H. Gee; "Heating of Ventilated and Enclosed Motors," by W. Hartnell. Professor Silvanus P. Thompson's "Kelvin" lecture on the life and work of Lord Kelvin is included, and also a Paper by W. F. Long on electric street lighting, read before the Cape Town Local Section. The number concludes with the following original communications:—"On the Measurement of Large Inductances containing Iron," by Sir Oliver Lodge and Mr. B. Davies; "Magnetic Reluctance of Joints in Transformer Iron," by Dr. H. Bohle.

Electricity Supply in Naples.—An article in the *Atti della Assoc. Elettrot. Italiana* describes a scheme for supplying cheap electric power to Naples. There are at present three companies supplying power, with a total plant capacity of 20,000 h.p., and the price is about 1·0d. per h.p. hour. It is proposed to utilise the water-power of the Volturno at a point some 90 km. distant from Naples, where over 60,000 h.p. is available. The water will be carried along a canal 2,400 metres long, to a reservoir from which it will be delivered to the station through a pipe-line consisting of three steel pipes, each 1·3 m. in diameter and 1,200 m. long. In the station there will be seven turbine units of 2,000 kva. capacity each, running at 375 r.p.m., and generating 50-cycle three-phase current at 2,000 volts. The pressure will be transformed up to 45,000 volts for transmission. Steel poles will be used for the transmission line, which will be composed of six conductors of 55 sq. mm. section each. At the main sub-station in Naples the pressure will be transformed down to 6,000 volts. Two 1,600 kw. steam units will also be situated in this station as a reserve. The smaller sub-stations will transform down from 6,000 volts to the 260 volts distribution pressure. It is thought that the charge for power will be about 0·3d. per h.p. hour. The total cost of the whole installation, including the transmission line and the main sub-station, works out at about £28 per h.p.

The British Association.—The following Papers of electrical interest are now announced as down for reading before Section A of the forthcoming meeting of the British Association at Dublin:—"Secondary Radiation," by J. G. A. Hemsalach; "Do the Radioactive Gases (emanations) belong to the Argon Series," by Sir William Ramsay; "Discharge from the Wehnelt Cathode," by Dr. F. Horton.

LOCAL NOTES

ABERDEEN: *System of Charging.*—A sub-committee has been appointed by the Electricity Committee to consider and report as to whether a system of charging other than the present should be adopted.

AMBLE: *Electric Lighting Scheme.*—A scheme has been proposed for the construction of a suction-gas-driven generating station, and it has been agreed that the council form themselves into a committee to go into the subject fully.

BARNES: *Electricity Supply.*—The District Council is to extend distributing cables at a cost estimated at £90, and G. Smith & Sons are to wire fifty houses. Another extension of mains is to be made at a cost estimated at £55 in order to enable 20 houses to be wired, the application having been made in this case by Hunt & Son. To more effectively check coal consumption, the Electrical Engineer is to instal a Lea recorder for accurately measuring the whole of the water evaporated. The estimated cost of the apparatus is 60 guineas. The Law and Parliamentary Committee of the Council has postponed the question of proceeding further with opposition to the Electric Supply Bills (against which petitions were presented).

BATLEY: *Electricity Accounts.*—The net profit for the year ended March 31st on the Corporation Electricity Department has been £121.

BELFAST: *New Tramway Extension.*—Lieut. Col. Druitt held a Board of Trade inspection of the new Queen's Road tramway extension, which has been built to facilitate access to the shipbuilding yards, by the Harbour Commissioners, at a cost of £17,233. The Corporation has agreed to work the lines for a term of 21 years at a rental of 3¾ per cent. of the cost of construction, and will also maintain the lines. The contractors for the lines were Messrs. Dick, Kerr & Co., and operations were commenced on March 31st last, and completed on July 22nd, notwithstanding the large number of crossings necessitated by the frequent intersection of the route with the railway lines, and six swing bridges required to permit the passage of boilers and other heavy machinery. The line has been opened for traffic.

Tramway Accounts.—The total revenue for the year ended March 31st, 1908, amounted to £193,813, and the total number of passengers carried during the year was 45,233,122, which is 130 times the population of Belfast. The total car miles run during the year amounted to 5,808,901. The total working expenses were £119,823, or 62 per cent. of the gross revenue. The traffic expenses worked out to 2·46d. per car mile, this, with the addition of 1·05d. for general repairs and maintenance, 0·37d. for power, and 0·56d. for management and other expenses, gives a total of 4·94d. for working expenses, which compares very favourably with any Corporation tramway system. The gross trading profit thus amounted to £73,990, which, after the payment of interest, sinking fund, income tax, and an annual contribution of £8,962 to the general purposes fund of the Corporation, left a final surplus of £4,306, which will go towards wiping off the balance of the debit of the net revenue account. Two fatal accidents are reported during the year, but in neither case could the driver avoid anything which had occurred. The average number of units used per car mile was 1·25. The average traffic revenue per care mile was 7·84d. and the average fare paid per passenger was 0·99d.

BENWELL (NEWCASTLE): *Electricity Supply Schemes.*—A public meeting was held last Thursday at Newcastle to consider the desirability of a supply of electricity being provided for the districts of Benwell and Fenham. It appears that a provisional order was obtained by the Benwell and Fenham District Council in 1901, and in 1904 an arrangement was made with the Newcastle District Electric Lighting Co., but this was not carried out owing to the incorporation of the district into the city. An agreement was then made with the Corporation, who applied for a loan to cover the cost of mains, &c., but this was not granted. The following resolution was carried :—"That this meeting of residents of Benwell and Fenham calls upon the Corporation to assure the district that an efficient electric light service will be provided without further delay, and that a deputation be appointed to urge the Corporation to allow the electric lighting company to do so until a satisfactory solution of the matter can be arrived at.

BLACKBURN: *Electricity Accounts.*—Blackburn's Borough Treasurer issued his annual report on Friday last. The electricity account revealed an expenditure of £17,743. Generation absorbed £9,274; repairs and maintenance, £2,922; lamps, carbons, and fittings, £1,497; rates and taxes, £2,611; and management expenses, £1,438. The income was £34,761, giving a gross balance of £17,018, of which interest and sinking fund absorbed £15,574, leaving a net profit of £1,444 for reserve fund account. Sale of current produced £32,012, rentals of motors and lamps £1,204, and sales of lamps and fittings £1,544. The total expenditure on the electricity works up to date was £261,780, and the debt £200,540. The electric tramways involved an outlay of £38,197, of which traffic expenses were £14,106, general expenses £3,200, repairs and maintenance £9,087, and power expenses £11,804. The income reached £59,822, or a gross balance of £21,625, of which interest and sinking fund accounted for £20,820, leaving a profit on the year's working of £804, carried to the reserve account. The capital expenditure on tramways was £325,527, and the debt stood at £226,405. Passengers' fares were £57,566, and receipts from parcels, advertising, and rents amounted to £2,256.

BLAIR-ATHOLL: *Electricity Lighting.*—The village is now electrically lighted from a water-power station which the Duke of Atholl has established for the lighting of Blair Castle.

BO'NESS: *Extensions.*—A reply has been received from the Secretary for Scotland to the application for a loan of £7,000 to defray the cost of new machinery and plant, but disapproval is expressed with regard to the proposal to avoid the formation of a reserve fund.

BRIERFIELD: *Supply to New School.*—The Council decided on August 13th that the application of the Education Committee for a supply of electricity to the new school be granted, subject to an agreement being entered into regarding a minimum supply covering a period of five years.

BRIGHTON: *Charges for Electricity for Districts Outside the Borough.*—Some readjustment has been decided upon of the charges for electricity within the parishes of Preston Rural and Patcham. A flat rate of 4½d. per unit will be charged for the lighting, and 2d. for power, with 2s. 6d. per quarter rental for meters. It will be remembered that the price in Brighton is now 4d., as the maximum demand system of 7d. and 1d. has been discontinued for some time.

BURTON-ON-TRENT: *Reduction of Tariff.*—The Gas and Electricity Committee have just decided to reduce the charge for current for outside arc lighting from 5d. to 4d. per unit. This reduction applies only to arc lamps which overhang the public footway, and are on the exterior of the building when closed, and the only stipulation is that the wiring which supplies the arc lamps shall be continued to the Corporation's cut-out, so that a meter may be fixed there, which will be done free of charge and meter rent. This reduction has been conceded because the use of arc lamps, particularly flame arc lamps, assists in the illumination of the streets, and generally benefits the town. These lamps also prove a very good advertisement for the Electricity Department.

CHALFONT ST. PETER: *Public Lighting.*—The Parish Council, which is considering the best method of lighting for the village, has asked the Uxbridge Gas Co. and the Uxbridge Electrical Co., and the Gerrards Cross & District Electrical Co., to give estimates of the cost of fixing lamps (the number of which is to be decided by a Council sub-committee), and all necessary fittings. At a meeting of the Parish Council, Mr. Price, of the Uxbridge Gas Co., advised brackets fixed on walls for the lights, rather than standards. It would be possible to turn the lamps on or off without employing a lamplighter, but at the present stage the cost would be £1 10s. extra per lamp.

CRAYFORD: *Proposed Supply Scheme.*—A Committee of the Parish Council is to consider the question of lighting the parish by electricity. At the last meeting of the local authority Councillor Hopper said that after study of figures, he felt confident that the district could be lighted much better by electricity than by gas.

DEWSBURY: *Supply of Electricity to the Tramways.*—The National Electric Construction Co. has agreed to the price of 1¾d. per unit as the price to be paid to the Corporation for electricity to be used on the portion of the Dewsbury to Ossett tramways within the borough, and the Electrical Engineer has been instructed to make preparations for giving the supply.

DUBLIN: *Proposed Adoption of the Trackless Trolley System.*—A movement is on for the introduction of the new system of trackless electric tramways in Ireland, the first contemplated route being between Donnybrook, in the suburbs of Dublin, and the pretty seaside resort of Bray. The new system, it is said, can be worked inexpensively on the existing roads from power derived from the usual overhead wires. The project has been submitted to the manager of the Dublin United Tramways Co., and to the County Council.

DUNDEE: *Electrical Laboratories.*—The erection of the new Peters' Electrical Laboratory at University College, Dundee, is to be proceeded with at once. The building, which is to cost £2,792, will consist of a lower floor containing battery room, high-tension instruments room, and dynamo rooms, and an upper floor devoted to lecture rooms and photometric and other test rooms. The remainder of the £4,000, forming the bequest of the founders, will be expended upon equipment.

Theatre Lighting.—During the interval in which Her Majesty's Theatre has been closed, a complete electrical equipment has been installed. Not a single gas jet is now to be found behind the scenes. The work has been carried out by Her Majesty's Theatre's chief electrician, while Mr. Richardson, the Corporation Electrical Engineer, has also given his advice and assistance in the carrying out of the work.

EALING: *Dispute as to Supply.*—In reference to the case by the Corporation against the Empire Palace (Ealing) Ltd., and the London Theatres of Varieties, Ltd., for supplying current in bulk to a restaurant on the theatre premises occupied by Lipton's, Ltd., the defendants have entered an appeal against

Digitized by Google

the decision of the justices, in view of the fact that they ordered payment of costs against the company, although they dismissed the information.

FARNHAM: *Electric Lighting Scheme.*—At a recent meeting of the Urban District Council a letter was read from Mr. Roumieu, of the Farnham Electric Lighting Co., containing plans and particulars of the company's scheme for the whole district, showing the positions of the poles and overhead wires proposed. After some discussion as to the possibility of placing the poles behind houses, the matter was referred to the Public Works Committee.

HAMPTON: *Tramways and Telephones.*—The following councils have been invited to attend a conference to take into consideration the present condition of the permanent way of the London United Tramways, and its method of construction, with the view to some united course of action being taken in order to obtain improvement :—The town councils of Ealing and Hammersmith, and the urban district councils of Twickenham, Chiswick, Acton, Brentford, Southall-Norwood, Teddington, Hampton Wick and Hounslow. A letter was received recently from the London United Tramways, Ltd., stating that they propose to continue the work of repairing the permanent way within the Hampton district upon which their workmen were engaged until everything needing attention should have been completed. The company also intimated an intention to apply a new type of silencer to certain spring points. The District Council has resolved that the attention of the Metropolitan Police Commissioner be again called to what they contend to be the unsatisfactory condition of a number of the cars of the London United Tramways, Ltd., whereby considerable noise and annoyance to residents along the route is caused. At the last meeting of the District Council the Clerk reported that he had also invited the urban district councils of Hampton Wick, Twickenham, Teddington, East Molesey, and Sunbury to attend a conference on the proposal of the Postmaster-General to extend the telephone system in the district, and for that purpose to construct overhead wires, with a view to uniformity of action on the part of the councils interested in the case of the present, and of any subsequent similar applications. Replies having been received from Twickenham, Teddington, and Sunbury, it was decided that the Postmaster-General be informed, in reply to his application for a general consent, that each case will be treated on its merits.

HASLINGDEN: *Electricity Supply.*—At a meeting of the Building Committee of the Haslingden Board of Guardians on August 13th, a communication was read from the Rawtenstall Corporation declining to supply electricity at the rate of 3d per unit as the Board had agreed. A letter had been received from the electric advisers of the Board, and it was decided to ask them to meet the committee in a fortnight.

Tramways.—The Haslingden tramway tangle now bears a different complexion. A close scrutiny of the clause causing the difficulty shows that it explicitly permits the provision of mechanical power, including electric and other plant, for the working of the tramways, but states that nothing in it shall empower the construction of a generating station. The two things are contradictory. The Corporation, it is stated, are appealing to the Board of Trade, and if this authority will rule that the Corporation may take the complexion that it is only a generating station as a building that the Act does not sanction, the difficulty will be simplified, for the cost of the building will be small compared with that of the plant.

HYDE (CHESHIRE): *Electricity in Textile Mills.*—Messrs. Ashton Bros., Ltd., of the Carrfield Mills, Hyde, Cheshire, have just had coupled up several large electric motors for driving machinery in the weaving, winding, warping, and slashing departments. Not a single hour was lost by the operatives during the change over from steam driving.

HYTHE: *Proposed Tramways.*—At a recent meeting of the Town Council it was reported that the General Purposes Committee had interviewed Mr. Cownie, of the National Electric Construction Co., who had informed them that his company had decided not to adopt the Dolter surface-contact system for the tramways when laid. He proposed, therefore, the substitution of the overhead system, and also some modifications of the route, in order to save expense, as the company were not prepared to find the capital required for the original scheme. They recommended the acceptance of these recommendations, but after considerable discussion it was decided to defer the matter until a poll of the ratepayers had been taken.

LLANDILO: *Light Railway.*—The Board of Trade have confirmed the Llandilo and Lampeter Light Railway Order, 1908, authorising the construction of a light railway in the counties of Carmarthen and of Cardigan, from Llandilo to Lampeter.

LONDON: *St. Pancras.*—In connection with the proposed construction by the London County Council of a tramway on the conduit system through Crowndale Road, from High Street, Camden Town, to Pancras Road, the suggestion is made that a bridge should be constructed over the Metropolitan Railway Station at King's Cross, but the Islington and St. Pancras Borough Councils decline to make any contribution towards this project, contending that the entire cost should be borne by the general tramway account.

LOWESTOFT: *Free Wiring.*—The Electric Lighting Committee have resolved that a clause shall be inserted in all free wiring agreements providing for a minimum payment.

The Borough Electrical Engineer has been directed to submit a plan showing the suggested lighting by electricity of 14 streets, with the price per lamp, and the cost of lighting each street. At the last meeting of the Town Council it was reported that the cost per lamp would not exceed the present cost per lamp for incandescent gas.

MIDDLESEX: *Tramways.*—Progress is being made with the track construction of the Friern Barnet Road and Woodhouse Road section of the Middlesex County Council's tramways, which will link up Southgate and Barnet, and contracts, amounting to £157,198, have been entered into for lines through Hendon and Finchley, linking up the Edgware and Barnet systems and from Southgate to Enfield.

NELSON: *Electricity Accounts.*—In his annual abstract of accounts this week, the Borough Treasurer of Nelson stated that the electricity department made a profit of £3,023, equal to 4·10 per cent.; the electric tramways £788 (7·08 per cent.), and the light railways £843 (2·36 per cent.).

OLDHAM: *Interruption of Supply.* At a meeting last week of the Electricity Committee, it was reported that the recent interruption of supply to the tramways was due to steam having got low, owing to the carelessness of two stokers, who had let their fires get dirty.

PORTSMOUTH: *Electricity Accounts.*—The accounts for the year ended March 31st last show a total expenditure of £26,639, made up as follows :—Generation, £17,574; distribution, £2,054; public lamps, £1,931; rents, rates, taxes, management, special charges, &c., £5,080. The total receipts were £48,312. Of the balance of £21,733, interest, sinking fund, &c., absorbed £18,248, £1,000 was transferred to insurance fund, and £150 was contributed towards capital outlay; £2,000 was voted in aid of rates, and £335 was carried to reserve. The amount contributed to the rates last year was £3,500, with £5,991 carried to reserve. The total units sold amounted to 3,294,040, including 648,791 for public lamps, so that the total cost per unit sold, not including capital charges, works out at 1·895d., or, with the inclusion of capital charges and contributions to reserve, at 2·64d. The maximum supply demanded was 2,680 kw., which gives an average load factor of 12·8 per cent.

RHONDDA VALLEY: *Proposed Lease of Tramways.*—It is announced in the *London Gazette* that it is proposed to lease the tramway undertaking of the Rhondda Urban District Council to the Rhondda Tramways Co., Ltd., with the consent of the Board of Trade, for a period of 42 years, at a yearly rental of £2,250.

ROSARIO (Argentine): *Tramways.*—According to a consular report, the electric tramway service, which is in the hands of a Belgian company, is nearing completion, and several sections have been inaugurated during the year. Suburban property has consequently risen in value. The extent of track when completed will be 75 miles, and the total cost over £750,000.

TAUNTON: *Tramways.*—The agreements between the Taunton Traction Co., the British Electric Traction Co., and the Corporation, which are due to expire very shortly, are to be renewed with modified conditions, including the construction of the Rowbarton extension, and the opening of the same for public traffic as early as might conveniently be done, and not later than six months from the present date.

TORQUAY: *Charges for Power.*—The Electrical Engineer has recommended that the following charges be made to consumers whose demand is continuous for at least eight hours per day on an average; for the first 200 units per annum 2d. per unit, and the next 100 units 1½d. per unit, and for all consumed above this amount 1½d. per unit.

Tramways.—A visit has been paid to Torquay by a deputation of engineers from Paris, who are studying various tramway systems with a view to arriving at greater uniformity in the Paris tramways. A full inspection was made of the Dolter surface-contact system, which is in use at Torquay.

TOULON (FRANCE): *Cessation of Supply.*—In consequence of the lighting company having been unable to obtain payment of an account from the municipal authorities, the supply was entirely cut off on Friday. As a means of putting an end to this state of affairs, the municipal authorities are considering the question of floating a loan to enable them to pay the company.

WAKEFIELD: *Reduction of Tariff.*—The charge for electricity used for domestic purposes other than lighting is to be reduced to 1d. per unit.

Telegraph Traffic.—The past week has again been a very quiet one, for not only have there been no interruptions of telegraphic communication to report, but also no repairs, with the exception of the lines of the Indo-European Telegraph Co., which were again restored to working order on the 13th inst. The cable between Cadiz and Teneriffe, which is rather unfortunate in its experiences, is in part being diverted from its present bed, and in consequence is not in a good working condition. The Tarifa-Tangier, Assab-Massouah; Kwandang-Menado, Djedda-Souakim, Sierra Leone-Accra, Las Palmas-Arecife, and Pera-Dardanelles cables are still interrupted. One hundred and seventy-five knots of new cables have recently been landed in the island of Hayti, West Indies.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRIA-HUNGARY.—According to the *Hungarian Official Gazette* of July 30th, tenders are invited up to 10 a.m. on September 3rd by the Municipality of Nagy-Kanizsa for the installation of electric plant for the lighting of that town. The contract is to be: (1) For the erection of the necessary buildings; (2) for the mechanical fitting up of the electric plant; (3) for the necessary supply of water-power; (4) for the electrical installation; (5) for the necessary materials for secondary installation (*secundärinstallaczión*). Plans, conditions of tender, &c., may be obtained on application at the office of the Town Engineer (Varosi Hernoki Livatal, Nagy-Kanizsa), at a cost of 150 crowns (£6 5s.). A copy of the notice inviting tenders (in Magyar) may be seen by British contractors on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

BRIDGEND.—The Council has decided to apply a loan of £3,250 to the purchase of the South Wales Electrical Power Co.'s station at Bridgend, and works connected therewith. The cost of the station as it stands is £5,000, and the remaining £3,250 will be devoted to mains extensions, pumping plant, refuse destructors, and an hydraulic coal tip.

ITALY.—A report has been issued by the Italian Ministry of Agriculture, Industry, and Commerce on electrical installations authorised in Italy during 1907. The report may be seen by British firms interested on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

KINGSTON-ON-THAMES.—A Local Government Board inquiry was held on Tuesday into an application for a loan of £12,600 for the purposes of the Electricity Department.

SALFORD.—A Local Government Board inquiry was held last week into an application for a loan of £15,281 for the purposes of the electricity undertaking by Mr. F. H. Tulloch. The sum is made up as follows: £11,707 for water-cooling plant, £578 for expenditure on the turbo-generators at the works, and £3,000 for extensions to the Prestwich electric lighting system.

TONBRIDGE.—A Local Government Board inquiry was held last week into the Council's application for a loan amounting to £4,200 for extensions to the generating station. In the course of the inquiry the inspector suggested that the Board should not be pressed to sanction the cost of certain portions of the work, including boilers and accessories, which would not be required until next year, when the cost might be sanctioned without further inquiry.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Premises in Seven Sisters Road, for London and South-Western Bank. Muskett & Co., surveyors, 491 High Road, Tottenham.

S.E.—Police station, &c., at Greenwich (£23,220). J. Dixon Butler, surveyor, New Scotland Yard, S.W.; Patman & Fotheringham, builders, 100 Theobalds Road, W.C.

Thirteen houses, Lewisham. H. & G. Taylor, builders, Boyne Road, Lewisham.

Ten houses, Lewisham. W. J. Scudamore & Sons, builders, 13 Manor Lane, S.E.

Four houses, Lewisham. Jas. Watt, builder, Bromley Road, Catford, S.E.

Business premises, Perry Hill. J. W. Falkner & Sons, builders, 24 Ossory Road, Deptford, S.E.

Benedictine monastery and church at Dulwich. J. N. Cowper, architect, 35 Old Queen Street, S.W.

W.—Shops and flats, Henrietta Street and Wimpole Street. W. King & Son, builders, 3 Vauxhall Bridge Road, S.W.

Extension to 39 Duke Street, by W. Smith, shirt-maker, &c., 396 Oxford-street.

Re-erection, Nos. 13 and 14 Great Castle Street. H. Kingerlee & Sons, builders, Shepherd's Bush.

W.C.—Addition to Whitfield's Tabernacle, Tottenham Court Road. W. Downs, builder, Hampton Street, Walworth.

PROVINCES.

ABERDARE.—Baptist Sunday school (200 places). Architect, J. Llewellyn Smith, Central Chambers, High Street, Merthyr Tydfil.

ASHTON-UNDER-LYNE.—School (1,200 places). D. H. Wade, Secretary Education Committee.

BARNES.—Twenty-one villas, Fitzgerald Estate, and four villas, Mortlake. Architect, R. B. Rowell, Triangle Corner, East Sheen, S.W.

Alterations, Working Men's Institute. Architects, Bartlett & Ross, 8 Bream's Buildings, W.C.

Three houses, Mortlake. Builders, C. Ellis & Co., East Sheen.

BARNSLEY.—Alterations and additions to Liberal and Radical Club, Market Street.

BECKENHAM.—Iron art school (£2,000), and alterations (£1,100) to Technical Institute, for District Council. Surveyor, J. A. Angell.

BLACKPOOL.—Methodist Free Church, in Shaw Road.

BOLTON.—New premises in Bradshawgate, for National Provincial Bank of England.

BRISTOL.—Mission Church, Bedminster (£2,750). Builder, T. Weeks, 6 Beauley Road, Bedminster, Bristol.

BURY.—Extensions to offices, Town Council. Surveyor and Engineer, A. W. Bradley, Town Hall.

Alterations and additions to mill. Architect, A. J. Howcroft, 2 Waterloo Street, Oldham.

Alterations and additions to Grammar School. Architect, H. Nuttall, Bury.

Fourteen houses. Architect, Wm. E. Gill, 6 Fleet Street, Bury.

CARDIFF.—School (£12,000). Architects, Teather & Wilson, Andrew's Buildings, 67 Queen Street, Cardiff.

Additions to Secondary School (£3,500). Architects, James & Morgan, Charles Street Chambers, Cardiff. Builder, F. Bond, 49 Beda Road, Cardiff.

DARLINGTON.—Science class rooms. Architects, Clark & Moscrop, Feethams, Darlington.

United Methodist Chapel, Blackwell.

DUDLEY.—Training college (£10,800); also secondary school. J. M. Wynne, Secretary Education Committee.

FRIERN BARNET.—Development, Bethuen Estate. Architects, Bennett & Strutton, Broadway, Finchley.

FRIZINGHALL.—Wool warehouse. Architect, Abraham Sharp, Market Street, Bradford.

GRANTHAM.—Additions to Co-operative premises, St. Catherine's Road, for Grantham Co-operative Society.

HAVERFORDWEST.—Additions to workhouse. Architect, E. Thomas & Son, 17 Victoria Place, Haverfordwest.

KENDAL.—Business premises, motor garage, and workshops. Architect, John Hutton, Kendal.

LEEDS.—Corporation stores. Architects, Connen & Chorley, 16 Park Place, Leeds.

LEYTON.—Proposed increased installation of electric light by Frank Bearman, house furnisher, draper, &c., 859 High Road.

Shops, stores, and house for Stratford Co-operative Society, 54 Maryland Street, E.

Increased office accommodation (£8,500) for District Council. W. Dawson, surveyor, Town Hall.

Additions to factory. A. W. Hudson, architect, 87 Finsbury Pavement, E.C.

Additions to offices. W. Manders, builder, Leyton Green.

Alterations to beerhouse. W. G. Ingram, architect, 4 Verulam Buildings, Gray's Inn Road, W.C.

MERTHYR TYDFIL.—Twenty-two houses for Gellifaelog Building Club.

NETHERTON.—Additions to training school. Armstrong & Wright, architects, 38 Grainger Street West, Newcastle-on-Tyne.

NORTHAM APPLEDORE (DEVON).—School (£3,000). Percy Morris, architect, 1 Richmond Road, Exeter; A. W. Coles, builder, Plymouth.

PERTH.—Infirmary (£50,000). John Jas. Burnett, architect, 239 St. Vincent Street, Glasgow.

SHEFFIELD.—The sanction of the Local Government Board has been obtained for a loan of £1,500 for fitting electric light at the Lodgemoor Hospital.

SOUTH SHIELDS.—Fourteen houses. Architect, H. Grieves, 63 King Street, South Shields.

Two villas. Architect, J. H. Morton, 50 King Street, South Shields.

Additions (cellarage) to business premises. Architect, G. R. Smith, 67 King Street, South Shields.

SWINDON.—Additions to Borough Press Works, Eastcott Hill.

TOTTENHAM.—Dancing hall for Union Club, Ltd., 14 Bruce Grove.

Additions to workshop, Derby Road, for Atlas Metal and Alloys Co., Ltd., 52 Queen Victoria Street, E.C.

Nineteen houses. Builder, G. W. Rowley, 278 Philip Lane, N.

Forty-nine houses. Architects, Hodson & Whitehead, 7 Finsbury Square, E.C.

Factory in Fountayne Road, for Clark & Co., piano frame makers, Broad Lane Ironworks, Tottenham.

TWYNYRODYN.—Additions (£8,700) to school. Architect, J. Llewellyn Smith, Central Chambers, High Street, Merthyr Tydfil. Builder, A. J. Colbourne, Swindon.

WEMBLEY.—Four houses. Builder, W. Poulter, 59 St John's Road, Wembley.

Digitized by Google

WEST BROMWICH.—Extensions of Wellington Tube Works, Blades Street.

YORK.—Eight semi-detached villas. Architect, J. C. Proctor, Cabinet Chambers, Basinghall Street, Leeds.

Miscellaneous

ANTWERP.—Tenders are invited by the municipal authorities of Antwerp for the supply and erection of four electric bollards on the quays of the Royers Lock at Antwerp. A deposit of 5,000 francs (about £200) will be required to qualify any tender. Tenders, enclosed in sealed, registered envelopes, should be addressed to Monsieur le Bourgmestre de la Ville d'Anvers, Hôtel de Ville, Antwerp, by whom they will be received not later than August 31st. The specification (*cahier des charges*) may be obtained from the Hôtel de Ville, at a cost of 0·50 franc. A copy may be consulted by British contractors on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

LONDON.—The Postmaster-General is inviting tenders for creosoting telegraph poles. Specifications from Mr. G. Morgan, controller of stores, Stores Department, General Post Office, 17-19 Bedford Street, and tenders by September 7th.

PERU.—The *Board of Trade Journal* reports that considerable extensions are in progress of telegraphs and telephones. In 1906 1,297 kiloms. were constructed, and 533 kiloms. in the first half of 1907. The lines to be constructed are from Locumba to Candarave and Ticaco.

TENDERS RECEIVED AND ACCEPTED

BLACKBURN.—The electrical fittings, &c., for the new Council school being erected in Accrington Road, Blackburn, by the local Education Committee, are being supplied and fixed by Mr. Thomas Barton, of the Electric Works, Blackburn.

GLASGOW.—Messrs. Mavor & Coulson have just completed the installation of a 100-h.p. motor at the saw-mills of Messrs. Anderson & Henderson. The motor was put in to replace steam plant which has broken down in order to save time, and there was only an interruption of two working days.

GRAVESEND.—The following tenders for arc lamps have been received :—The Brockie Pell Arc Lamp Co., £438 12s. 2d. and £554 2s. 2d.; Johnson & Phillips, Ltd., £534; Thomas L. Scott & Co., Ltd., £542 1s.; Oliver Arc Lamp Co., £551 17s.; the Gilbert Arc Lamp Co., £580 and £514; Warner Engineering Co., £600 15s.; Mackensie & Moncur, Ltd., £619; Crompton & Co., Ltd., £686. Owing, however, to all these tenders exceeding the engineer's estimate of £420, of which £100 was to be paid out of capital and the remainder, £320, out of revenue, it was decided to defer the matter for twelve months.

LOWESTOFT.—The following tenders have been received by the Electric Lighting Committee: Messrs. Parish & Durrant, street wiring work at a price of 7s. 6d. per point; Messrs. J. W. Brook & Co. for the supply of 50 new street lamp-posts at 33s. 6d. per post; Messrs. Melloine & Goulder (Ipswich) for the Bestwood nutty slack at 10s. 9d. per ton up to 1,500 tons; Messrs. E. Foster & Co. (London), 1,000 tons of Ibstock large steam coal at 14s. 5d. per ton; Messrs. Bradbury, 500 tons of cobbles at 14s. 11d. per ton. Consideration of further coal contracts will be made at a later date.

MIDDLESEX.—The tender of Messrs. Wimpey & Co., of Hammersmith, of £40,220, for the construction of 1½ miles of double track overhead tramways at Southgate, including some road widening.

ONTARIO.—The Government have awarded a contract to Mr. F. H. McGuigan for the construction of 293 miles of transmission lines from Niagara to St. Thomas and Toronto at a total price of £254,000. The contract includes the furnishing and erection of 3,176 steel towers and cables of aluminium wire, weighing 1,014,209 lb.

WAKEFIELD.—The tender of Messrs. Flower Bros. for boiler seatings at the electricity works at £110 has been accepted.

COMPANIES' MEETINGS AND REPORTS

A.-G. BROWN, BOVERI & CIE. (BADEN, SWITZERLAND).—The report for the year 1907-8 states that the works have been fully engaged during the year, and that the gross profits were considerably larger than in the previous year. The expenses, however, were also increased, and the net profit is not appreciably larger than that of last year. In September last year the capital of the company was increased from 16,000,000 to 20,000,000 francs by the issue of 3,200 new shares. The employees at Baden now number 3,090. The German firm at Mannheim has also been very busy during the year, and a dividend of 6 per cent. on the share capital of 6,000,000 marks has been declared. About 1,780 men are employed at these works. The capital of the Italian company, *Tecnomasio Italiano Brown, Boveri*, of Milan, which took over recently the business of Messrs. Gadda & Co., of Milan, has been increased to 6,000,000 lire. A dividend of 6 per cent. was declared for last year. The employees there number 1,020. The *Compagnie Electro-Mécanique, Paris-le-Bourget*, have also done well, a dividend of 8 per cent. having been declared. The London firm, *Brown, Boveri & Co., Ltd.*, shows increasing business, and the firm at Christiania has declared a dividend of 6 per cent., 1 per cent. higher than that of last year. The *Elektricitätsgesellschaft Baden* have reduced their dividend 5 per cent. on account of the heavy expenditure demanded by the new works on the Limmat. The accounts of the Baden company show a net profit of 2,351,445 francs, which enabled a dividend of 11 per cent. to be paid, as in the previous two years.

CHILIAN ELECTRIC TRAMWAY AND LIGHT CO.—The report for the year ended December 31st, 1907, states that the result of the company's operations for the past year, after deducting interest and redemption of debentures, London office and other charges, shows a balance of £14,160, from which must be deducted the balance to the debit of profit and loss account brought forward from the previous year, viz., £2,447, which leaves a balance available for distribution of £11,712. The sum of £10,000 has been transferred to renewals reserve account, leaving £1,712 to be carried forward The company has not so far been able to pay a dividend on the ordinary capital, and the preference dividends are still in arrear. All the preference shares, which amount to £650,000, are held by the Deutsche Uberseeische Elektricitäts-Gesellschaft of Berlin. The year under review has not been characterised by the untoward circumstances which so seriously affected the company's traffic in 1906, and consequently the tramway returns show a total of 61,451,234 pasengers carried, as against 50,998,903 carried for the previous year. The business of the electric lighting department shows a gratifying development on the figures of the previous year; the public continue to avail themselves both of the light and power in increasing ratio, and the profit for 1907 amounts to $470,928.81, against $510,448.89 for 1906. Unfortunately the continued depreciation of the Chilian currency has adversely affected the net profit resulting from the good receipts obtained in the tramway and electric lighting departments. At the meeting on Monday the report and accounts were adopted.

LOCH LEVEN WATER & ELECTRIC POWER CO.—At the half-yearly meeting last week Mr. J. D. Bonner, who presided, stated that the whole of the issued capital was held by the British Aluminium Co., who had agreed to subscribe for the balance authorised. They were thus in command of the funds necessary for the carrying out of the scheme. The progress at the works was so advanced that there was every indication that the production of aluminium at Loch Leven would commence some months earlier than had been anticipated. The report was adopted.

METROPOLITAN DISTRICT RAILWAY CO.—The half-yearly general meeting was held last week. In moving the adoption of the report and accounts, Sir George Gibb, who presided, said that the company was now in a much sounder financial position than it had been formerly. In referring to the projected issue of prior lien debenture stock, which had been approved and sanctioned, he said that it was not proposed to issue this until the holiday season was over. £550,000 would probably be issued in the autumn, but, from the point of view of liability for interest, this would practically replace the present temporary loans, which amounted to £478,195. The capital expenditure during the last half-year had been £59,499, and the estimated amount for the current six months was £75,000. This would be partly devoted to the development of surplus land, and to a number of improvements on the railway and the rolling stock, including the substitution of hand-worked doors for the pneumatic doors originally used, which were not popular with the public. During the period under review they had carried 29,500,000 passengers, an increase of 16½ per cent., and the receipts had advanced by £27,433, or 13½ per cent. over the corresponding half of 1907. The average receipts per passenger worked out at 1·86d. With regard to the extra traffic attributable to the Franco-British Exhibition, he did not think that the railway had benefited to any great extent directly—in fact, to some extent it had suffered from the diversion of traffic from the Hungarian Exhibition at Earl's Court. In his own opinion these special circumstances had not added more to the traffic than they were likely to get in future ordinary seasons. The net result of the half-year's working, after payment of debenture interest, was a deficiency of £8,951. When this was compared with the figure of £18,035 for the corresponding half of 1907, it would be seen that the position had increased by roughly £9,000. The deficiencies were getting every year smaller, and he hoped that before long they would disappear altogether. After some remarks from a shareholder, who complained of the inconvenience suffered by passengers residing on the Inner Circle caused by the excessive delays at Gloucester Road and South Kensington, with regard to which

Digitized by Google

the chairman was unable, however, to promise any definite improvements, the report and accounts were adopted.

NORTH METROPOLITAN TRAMWAYS.—At the half-yearly meeting last week Mr. George Richardson referred to the sale of the Romford Road tramways to the East Ham Corporation, with the proceeds of which a return of 2s. per share was proposed. At a subsequent extraordinary meeting this reduction of capital was agreed to. It had been proposed at one time to put the company into liquidation in order to save an application to the Courts for this disboursement, but it was decided to wait until the outstanding debenture bonds fell due for repayment on January 1st next. These amount to £51,700, and the necessary funds are now at the bank.

WILLANS & ROBINSON.—At a meeting of debenture holders, held on Friday, Mr. Mark Robinson presiding, a resolution was passed authorising the directors to sell the company's leasehold interest in the Queensferry works, and to invest the sum realised in securities or in the purchase of plant, provided that not more than one-third of such proceeds of sale be applied in the purchase of plant.

COMPANY MORTGAGES

BOURNE END ELECTRIC INSTALLATION CO.—Particulars of £2,000 debentures, created by resolution of July 17th, 1908, have been filed. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees. All above debentures have been issued.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under Section 14 of the Companies Act, 1900, has been filed pursuant to Section 12 of the Companies Act, 1907. Particulars—Trust deed, dated November 21st, 1900, securing £400,000 first debenture stock.

BUENOS AYRES GRAND NATIONAL TRAMWAYS CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Trust deed dated May 11th, 1894, and sundry supplemental deeds, under which £148.300 is outstanding, and income debenture bonds dated March 30th, 1894, securing £74,523.

BUENOS AYRES NEW TRAMWAYS CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Prior lien debentures dated July 28th, 1893, securing £50,000 and debentures dated October 24th, 1888, securing £250,000.

ELECTRICITY SUPPLY COMPANY FOR SPAIN.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under Section 14 of the Companies Act, 1900, has been filed. Particulars—Two charges on realty in Spain and the company's other assets, dated 1892 and 1893, securing £75,000 First and £42,500 "B" debentures, of which £32,800 and £18,200 respectively are outstanding, and trust deed dated November 30th, 1898, securing £250,000 Consolidated Debentures, of which £121,200 are outstanding.

THE ELECTROMOBILE CO.—A memorandum of satisfaction in full of a mortgage dated July 19th, 1906, securing an indefinite amount, but stamped to cover £20,000, has been filed. A mortgage dated March 25th, 1908, to secure £12,000, has also been registered. Property charged: Interest under an agreement for lease of certain freehold hereditaments, and assignment of certain leasehold hereditaments in St. George's, Hanover Square, W., and the company's undertaking and property, present and future, including uncalled capital. Holders: North of England Trustee, Debenture and Assets Corporation, Ltd., 104 King Street, Manchester.

GLOUCESTER RAILWAY CARRIAGE AND WAGON CO.—Issue on July 22nd, 1908, of £2,800 debentures, part of a series of which particulars have already been filed.

W. T. GLOVER & CO.—Deed of exchange, dated July 23rd, 1908 (supplemental to indenture, dated October 14th, 1901, and to trust deeds, dated July 26th, 1899, securing £100,000 first mortgage debenture stock, and September 29th, 1906, securing £100,000 second debenture stock, of which only £80,000 has been issued), has been registered.

LA CAPITAL TRAMWAYS COMPANY.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under Section 14 of the Companies' Act, 1900, has been filed. Particulars—First and Second Mortgage Debentures, dated November 23rd, 1896, and November 25th, 1896, securing £110,600, and £142,100 respectively.

LA CAPITAL (EXTENSIONS) TRAMWAYS CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Mortgages or charges dated February 10th, 1898, and October 1st, 1899; mortgage debentures securing £108,700 and £1,000 car trust debentures respectively.

MOUNTAIN & GIBSON.—Particulars of £30,000 debentures created by resolution of July 17th, 1908, have been filed pursuant to section 10 (3) of the Companies Act, 1907. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees. Amount of present issue, £20,000.

NORFOLK ELECTRICAL CO. (BIRMINGHAM).—Particulars of £1,000 debentures created by resolution of June 13th, 1908, have been filed pursuant to Section 10 (3) of the Companies' Act, 1907, the whole amount being now issued. Property charged—the company's undertaking and property, present and future, including uncalled capital. No trustees.

NORTHAMPTON ELECTRIC LIGHT & POWER COMPANY.—Particulars of debentures to secure not more than two-thirds of the subscribed and paid-up capital for the time being, created by resolution of June 3rd, 1896, have been filed. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees. Amount of present issue, £450.

A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—First mortgage debentures dated 1896 to 1900, securing £19,800, and second debentures dated November 15th, 1899, securing £3,600.

F. REDDAWAY & CO.—Particulars of £150,000 debentures, created by resolution of March 30th and April 15th, 1903, have been filed pursuant to section 10 (3) of the Companies Act, 1907, the amount of the present issue being £20,000. Property charged—The company's undertaking and property, present and future, including uncalled capital (subject to prior debentures). No trustees.

TRAFFORD POWER & LIGHT SUPPLY CO. (1902).—Deed of exchange, dated July 23rd, 1908 (supplemental to indenture, dated October 14th, 1901, and to a trust deed, dated February 14th, 1902, securing £75,000 first mortgage debenture stock), has been registered.—Trustees—North of England Trustee Debenture and Assets Corporation, Ltd.

CATALOGUES AND PAMPHLETS RECEIVED

ASPHALT TROUGHING.—The Howard Asphalt Troughing Co. have issued a catalogue describing their system of laying mains "solid" in asphalt troughing. The troughs are made in lengths of about 4 ft., and manufactured from natural rock asphalt, made continuous by welded joints. The cables are laid on the bottom of the trough. Asphalt separators are inserted between the cables. Hot bitumen is poured over the cables. Then hot asphaltic concrete is poured over the bitumen, welding the whole into a solid mass. The welding of one length of troughing to another is effected with a hot iron. The catalogue describes in some detail the method of laying by the aid of very clear illustrations of the actual processes being carried out, and includes also full instructions for sealing rubber tails to cables laid in Howard troughing.

COUNTRY HOUSE LIGHTING.—Messrs. Mavor & Coulson, of Glasgow, are sending out a calendar card for August, with a description of the lighting installation which they have carried out at Tandergree Castle in Ireland. The generating plant consists of a 25-B.H.P. steam engine direct-coupled to a shunt-wound dynamo, which is used in connection with a 54-cell accumulator battery. The wiring is on Messrs. Mavor & Coulson's "C.C." concentric system.

ELECTRIC COOKING OUTFIT.—A leaflet from the General Electric Co. contains particulars of a self-contained electric cooking outfit, consisting of an oven for roasting, baking, or stewing, with a hot chamber on top for heating plates, or keeping food warm; a large vegetable pan with steamer; a small pan for sauce, milk, or small vegetables, &c.; a hot-plate for boiling flat-bottomed utensils on, or keeping large pans gently simmering, &c.; and a frypan for chops, steaks, fish, &c. It is stated that this equipment can cook a dinner for eight persons for 4¾d.

ELECTRICITY SUPPLY.—The Hackney Borough Council are issuing a pamphlet entitled "A Logical Development," calling attention to the facilities for arrangements for electricity supply in the district, and pointing out the economies available with metal filament lamps.

HOUSE FUSE-BOXES.—A new catalogue from British Insulated & Helsby Cables Ltd. describes a great variety of patterns of house fuse-boxes. Some of these are combined with a special type of switch, the body of which consists of a porcelain drum, through which the switch blades pass, and all parts of the switch being balanced, thejarring effect produced by the operation

Digitized by Google

of the switch is reduced to a minimum. The spindle upon which the switch rotates is extended at each side of the cast-iron box, so that the handle may be fixed at either side, and all parts of the fitting can be readily removed and replaced. Except in the case of single-cable boxes, the sealing chamber is arranged so that cables may enter at either side or at the bottom, and fittings suitable for single, twin, concentric, triple concentric, or three-core cables are provided as required.

IRONCLAD SWITCHGEAR.—Messrs. Berry, Skinner & Co. are issuing a new list of their well-known "foul-proof" iron-clad switch and fuse gear. The main features of this gear were described in Electrical Engineering, July 2nd, page 26, in connection with the Franco-British Exhibition, where large numbers of these switches are in use. The switches are of the pull-off and push-on type. The moving part of the switch is actually a fuse-carrier, which is inserted into and with-drawn from its clips by the action of the switch. An in-genious arrangements of springs gives a quick make and break effect. The standard switches are listed up to 400 amperes at 500 volts. In sizes up to 100 amperes they can be combined with interlocked plugs for mining work.

METAL FILAMENT LAMPS.—The Electrical Co. have issued an attractive black and white show-card for the use of agents marketing their "Aegma" metal filament lamps. Other new publications relating to these lamps include an ingeniously arranged card calculator, and the shape of a lamp showing the saving obtained by, as against carbon lamps, for various prices of current. A circular also calls attention to the advantages of the "Aegma" lamp for shop lighting.

OSRAM LAMPS.—The General Electric Co. have sent us samples of their latest Osram show-card, which is a convenient size for shop windows and show-rooms, and has a gauze backing, rendering it equally suitable for a dark background or a window pane, the letters "Osram Lamps" standing out boldly in either case. A new circular containing testimonials relating to these lamps is also being issued, on the front page of which is a view of the auditorium of the Empire Theatre, showing lighting by Osram lamps.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire-bars, net c.i.f. port of arrival, quoted on Tuesday night, was £62 to £63 per ton (last week £64 to £64 10s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The adjourned public examination of Albert William Bennett (lately trading as Bennett & Co.), electrical engineer, of 43 Elford Grove, late 32 Park Cross Street, Leeds, was held on Tuesday last at the County Court House, Albion Place, Leeds, before the Deputy Registrar, Mr. Haigh. The liabilities were stated at £1,124, and there were said to be no assets, the debtor ascribing his failure to competition and bad trade. Debtor was further questioned, and the case was ultimately concluded.

A committee of inspection consisting of Mr. F. Taussig and Mr. F. J. Tiffin has been appointed to act with the official receiver as liquidators of the Kevan Electrical Co.

W. T. Garnett, trading as W. T. Garnett's Cable Co., of Barkerend Mills, Bradford, electric cable and wire manufacturer, has been adjudicated bankrupt. The first meeting will take place on August 26th, at 11 a.m., at the Official Receiver's Chambers, 12 Duke Street, Bradford. The public examination will be held on October 7th, at the County Court, Manor Row, Bradford, at 10 a.m.

WARNER ENGINEERING CO.—The manufacture of the Warner non-parallel axle truck under patent No. 15,059, 1905, has now been taken over by Messrs. Mountain & Gibson, Ltd., of Elton Fold Works, Bury, Lancs. A description of this truck was given in "Electrical Engineering," Vol. III., page 88. The conversion of existing trucks will be undertaken either by the Warner Engineering Co., or by Messrs. Mountain & Gibson, Ltd.

NEW PUBLICATIONS

"Electric Lighting and Power Distribution." By W. Perren Maycock. Seventh edition. (London: Whittaker & Co.). 6s.

"Journal of the Institution of Electrical Engineers," August. Vol xli. No. 191. (London: E. & F. N. Spon.) 5s.

APPOINTMENTS AND PERSONAL NOTES

On Friday last Mr. A. R. Howden was, on the occasion of his leaving to take up the position of Station Superintendent at Dumbarton, met by the members of the staff of the Dundee Electricity Department, and made the recipient of a handsome case of compasses. Mr. C. Lamb made the presentation, and in the course of a few remarks said they all regretted that Mr. Howden was leaving, and at the same time wished him every success in his new appointment. Mr. Howden suitably replied.

MISCELLANEOUS CITY NOTES

CHLORIDE ELECTRICAL STORAGE CO.—The year ended June 30th shows a profit of £24,945. A dividend of 10 per cent. is recommended, with £2,000 transferred to reserve, and £10,612 carried forward.

ELECTRIC TAXICAB CO.—The response to invitations for subscriptions for ordinary shares amounting to £300,000, has been so small that the promotors have not proceeded to allotment, and the application money has been returned.

NORTHAMPTON ELECTRIC LIGHT & POWER CO.—An interim dividend of 4½ per cent. has been recommended on the "B" ordinary shares for the past half-year.

RANGOON ELECTRIC TRAMWAY AND SUPPLY CO.—A prospectus has been issued inviting subscriptions at a premium of 2s. 6d. per share, for 10,000 six per cent. £5 Cumulative preference shares (being the balance of the 50,000 preference shares authorised), for the purpose of providing for extensions of the company's undertaking.

SOUTH AMERICAN LIGHT & POWER CO.—A dividend of 2 per cent. has been recommended on the ordinary shares, with £167 carried forward.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The scheme of readjustment having become binding, the company is now prepared to pay to note holders the amount of the coupon due July 1st, 1908 (representing seven months' interest from December 1, 1907), on the new 4½ per cent. bonds of 1933, to be given in part exchange for the notes.

NEW COMPANIES

BENJAMIN ELECTRIC CO.—This company was registered on August 8th, with a capital of £1,000 in £1 shares, to acquire from the Benjamin Electric Manufacturing Co., of Chicago, Illinois, U.S.A., the benefit of certain existing inventions, relating to electrical clusters and lighting specialities, and to carry on the business of electricians, producers, and workers of and dealers in electricity for power and lighting purposes, &c. The subscribers are R. B. Benjamin, B. J. Grigsby, A. Bathurst, and J. Lord. Private company. The number of directors is not to be less than two, nor more than six; the first are R B. Benjamin, W. D. Steele, W. C. Jones, K. H. Addington, and B. J. Grigsby No qualification necessary. No remuneration. Registered by Freshfields, 31 Old Jewry, E.C.

GENERAL RAILWAY SIGNAL CO.—This company was registered on August 10th, with a capital of £100 in £1 shares, to carry on the business of railway signalling engineers, manufacturers, and installers of, and dealers in, signal appliances, railway engineers, and contractors, electricians, electric, and pneumatic engineers, &c. The subscribers are:—J. Mortimer, G. Macleod, F. Doyle, P. Chadwick, W. H. Revz, S. Wall, W. Rushforth. Private company. Table "A" mainly applies.

PATENTS FOR SALE.

THE PROPRIETOR OF PATENTS Nos.
11933/00, "Improvements relating to the Regulation of Electric Motors."
19899/05, "Improvements relating to Alternating current Electric Motors."
26808/05, "Improvements relating to Alternating current Electric Motors."
is desirous of entering into arrangements by way of licence and otherwise on reasonable terms for the purpose of exploiting the same and ensuring their full development and practical working in this country. All communications should be addressed in the first instance to—

HASELTINE, LAKE & CO.,
Chartered Patent Agents & Consulting Engineers,
7 & 8, Southampton Buildings, Chancery Lane, London, W.C.

THE PROPRIETORS OF PATENTS Nos.
13287/02, "Improvements relating to Apparatus for the Transmission of Sound for Submarine Purposes."
13288/02, "Improvements relating to the Transmission of Sound for Submarine Purposes and to Apparatus therefor."
3266/03, "Improvements in Apparatus for producing Sound Vibrations in Water."
10463/04, "Improved means for producing Sound Vibrations in Water applicable to Marine Signalling."
10477/04, "Improvements in Apparatus for Receiving Submarine Signals."
14230/04, "Improvements relating to Submarine Signalling and to Apparatus therefor."
are desirous of entering into arrangements by way of licence and otherwise on reasonable terms for the purpose of exploiting the same and ensuring their full development and practical working in this country. All communications should be addressed in the first instance to—

HASELTINE, LAKE & Co.,

SUMMARY

The death is announced, from Paris, of Henri Becquerel, at the age of 56. (Page 308.)

A letter from "One of the Minority" objects to the wording of the official report of the special meeting of the Institution of Electrical Engineers, with regard to the acquisition of new premises on the Victoria Embankment. (Page 308.)

The following books are reviewed in this issue:—"Principles of Direct Current Engineering," by J. R. Barr; "Electrical Engineering," by W. Slingo and A. Brooker; "Some Quick and Easy Method of Calculating: A Simple Explanation of the Theory and Use of the Slide Rule, &c.," by R. G. Blaine; "Handbook of Farm Buildings, Ponds, &c., and their Appurtenances," by T. Winder, with a chapter on "The Application of Electricity to Farming and Agriculture," by J. W. Beauchamp; "Elektrotechnische Messkunde zugleich Leitfaden für das Elektrotechnische Praktikum," by A. Königswerther. (Page 309.)

The accounts of the Sheffield Corporation Tramways Department for the year ended March 25th, 1908, show that the undertaking is financially in a very good condition. The working expenses, excluding capital charges, amounted to 6·045d. per car mile; including capital charges, to 9·184d. per car mile. The total receipts amounted to 10·049d. per car mile. A sum of £22,532 was transferred to the General District Rate. (Page 310.)

An analysis of the accounts of the Acton Electricity Undertaking shows that the capital expenditure has been about £200 per kw. of maximum demand, although energy is bought in bulk, and therefore only converting plant, distributing network, &c., had to be provided. The loss, taking account of capital charges, has been 1¼d. per unit sold. (Page 311.)

In connection with the results of tests on the 5,000-6,000-kw. Willans-Siemens' turbo-alternator at Manchester, which we published in last week's issue, we reproduce this week the actual curve of steam consumption for the range of loads from 2,500 to 6,000 kw. The lowest consumption was 15·84 lb. of steam per unit at an output of 5,650 kw. (Page 311.)

In a Paper read before the Erfurt Congress of the Verband Deutscher Elektrotechniker, the question of the possible harmful influence on the eyes of the modern sources of artificial light was raised. The authors of the Paper remark that owing to the high temperatures of the latest types of electric illuminants, the proportion of ultra-violet rays in the emitted light has considerably increased. These rays, they point out, are injurious to the eyes, but can be entirely cut off by surrounding the light-source with a globe of special glass which absorbs all ultra-violet rays. In an article in a German contemporary, some experiments are described which show that these fears of injury to the eyes from ultra-violet rays in artificial light are

Digitized by Google

unfounded, as for a given degree of illumination, the proportion of ultra-violet rays in the light emitted from most electric lamps is less than that from sunlight. The danger of injury to the eyes through the influence of unequal illumination is emphasised in the latter Paper, and the importance of shading the new metal-filament lamps with frosted globes is insisted on. (Page 312.)

A large power station has been established by the Société de l'Energie Electrique du Nord de la France for the supply of electric power in the district of Lille Roubaix and Tourcoing. The station, which adjoins a canal at Wasquehal, is designed to contain turbo-generator sets aggregating 25,000 kw., of which plant representing 10,000 kw. is already complete or under erection. Current is generated at 10,000 volts 3-phase, at which pressure it is transmitted to substations, partly by cables and partly by overhead lines. (Page 313.)

A Paper read by Mr. S. B. Fortenbaugh at the Summer Convention of the American Institute of Electrical Engineers described the results of some tests on the leakage from the conductor rails of the London Underground Electric Railways, which show that the difference of potential between the positive conductor and earth is always normally considerably greater than the potential between the negative conductor and earth, and that a reversal of the polarity is always instantly accompanied by a considerable increase in the normal leakage current between the positive and the negative conductors. (Page 315.)

A railway contemporary publishes an interview with Mr. J. A. Boyd, a member of the Victorian Government, in the course of which some interesting information with respect to the electrification of the suburban railways of Melbourne was divulged. It appears that the report, which will shortly be presented by Mr. C. H. Merz to the Victorian Railway Commissioners, will recommend the electrification of some 40 miles of track, as a first instalment. The electrification will, it is expected, be carried out on the third-rail continuous-current system. (Page 318.)

A tramway accident resulting in injury to ten persons occurred in Liverpool on Friday last. A car with thirty passengers failed to stop at the usual stopping place at the bottom of a hill, and collided with a heavy lorry, falling over on to the same. The driver states that when he put on the hand-brake to stop the car, he failed to put the clutch in the proper position to engage in the teeth of the ratchet wheel at the base of the brake staff, with the result that the handle flew round and struck his elbow, temporarily disabling him. (Page 318.)

An interesting example of the application of electricity for lighting and power purposes is the installation in the West End premises of Messrs. Debenham & Freebody. The interior lighting is carried out chiefly with inverted arcs, but a large number of metal filament lamps are employed as well. All the arc lamp circuits, each of which consists of five lamps in series, are brought down to a central distributing board. An ingenious arrangement for indicating when the lamps require trimming is provided, and the method, by which the insulation of the system is kept continuously under test, is also very interesting. The cost of lighting each department is charged up separately to that department, and so special arrangements for metering the departments separately is provided. In the work-rooms are to be found electrically-driven sewing machines and electric irons, and there are many electric fans. Four of these fans are used in connection with a carefully designed ventilating system. This latter includes a complete installation of Ozonair apparatus for purifying the air. Electric lifts, electric clocks, and a very complete telephone system are also included in the installation. (Page 319.)

An article by Mr. H. R. Speyer describes the electrical equipment of a group of salt miles in Germany. Power is generated at a steam-driven power station, owned jointly by the several mining companies, electric driving is used for main winding engines on the Ilgner system, and for auxiliary 3-phase winders, and 3-phase motors are employed for underground haulage, aërial ropeways, tippers, elevators, cranes, pumps, crushing mills, and various other purposes. (Page 322.)

A short description is given of a form of oil circuit-breaker for a voltage of 75,000 volts, in use on one of the large transmission systems in the west of the United States. (Page 329.)

The exhibits relating to the heavier branches of electrical engineering at the Marseilles Electrical Exhibition cover a considerable range. Amongst them may be noticed examples of aluminium wires and cables, vehicles propelled by Edison accumulators, and examples of new designs of electrical machinery of interest embracing single-phase motors, rectifiers, double-current generators, as well as more usual patterns of machines. Examples of new forms of quartz mercury vapour lamps are exhibited, and a great number of applications of electrical power are exemplified. Another feature of the Exhibition is a large collection of maps, plans, &c., of transmission systems in France. (Page 330.)

Under Electrometallurgy and Electrochemistry notes are given on certain improvements in the electrothermic methods for oxidising atmospheric nitrogen and fixing it in the form of nitric acid, with a view to getting over the difficulties in producing highly concentrated nitric acid. At one time the mines of Coniston were famous for their copper ore, and large quantities were mined; at present they are not worked, the best part of the ore having been removed. There are, however, large clumps of tailings containing from 1·5 to 2·0 per cent. of copper. It is proposed to work this by an electrochemical process devised by Mr. T. Scott Anderson. Satisfactory trials of the process extending over two years are said to have taken place. (Page 331.)

Under "Electrical Science" in the British and American section, are notes on a method of calculating the resistances of spark gaps, and some experiments on Heusler's magnetic alloys. In a Paper abstracted in the Continental section, Athanasiadis describes a singing arc and rectifier obtained with a liquid anode. (Page 332.)

The water power station of the Great Northern Power Co., on the St. Louis River, contains four 7,500 kw. alternators, driven by vertical shaft turbines, working with a head of water of 378 ft., and running at 375 r.p.m. (Page 333.)

An article in an Australian contemporary describes the systems of electrical signalling in use in some of the large mines in the Kalgoorlie district. A 110-volt continuous-current system with motor-generator and stand-by battery is described. A 15-volt alternating-current system is in use in one mine, but it is stated that more trouble is experienced through electrolysis on alternating than on continuous-current systems. Telephones are not often employed. (Page 334.)

Among the Patent Specifications published by the Patent Office on Thursday last, is one by H. A. Mavor relating to a method of generating alternating current of variable frequency, particularly suitable for use in conjunction with electrical systems of marine propulsion with turbo-alternators running at a constant speed. The British Thomson-Houston Co. have a protective device, in which an insulating fluid is kept constantly flowing across the spark-gaps, to prevent the formation of arcs. A method of preventing the fall of tramway trolley wires when broken is the subject of a specification by A. G. Bonn and F. Mellaerts, and another taken out by the British Thomson-Houston Co. relates to the driving of machine tools with a reciprocating

Digitized by Google

motion by single-phase commutator motors. (Page 335.)

The running of electric accumulator omnibuses is proposed in Aberdeen.—A report of the Dublin Electric Lighting Committee recommending extensions, &c., costing about £70,000, has been considered by the Corporation, who have asked for a joint report by the Lighting and Finance Committees.—The Dunfermline Corporation have finally decided to hand over their Provisional Order to the Fife Electric Power Co.—The Board of Trade has promised to give the circumstances of Col. Yorke's inspection of the Ealing tramways full consideration.—A scheme has been proposed for the construction of a steep grade electric railway, partly in tunnel, in the City of Lincoln.—It is expected that the work on the electrification of the remaining horse trams in Battersea and Wandsworth will be taken in hand very shortly.—An automatic telephone exchange is to be established in Lyons.—The use of automatic tramway point controllers in Sheffield is being extended.—The prohibition of the importation into Turkey of electrical instruments has been withdrawn. (Pages 337 and 338.)

Applications for loans for electrical purposes are being made by the following local authorities:—Frome (£11,000); Kingston (£12,600); Stirling (£3,000); Whitehaven (£2,000).—Tenders are invited for feeder pillars, &c., by the Salford Corporation.—Further tenders for telephone material are required for Australia.—For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces.—The tender of the Western Electric Company has been accepted for a telephone exchange switchboard at Melbourne.—The Dublin Corporation have resolved to ask for new tenders for certain plant on account of a complaint that all the firms tendering had not been given equal opportunities for revising their tenders. (Page 338.)

Meetings have been held during the past week of the Dublin and Lucan Electric Railway Co., the Lanarkshire Tramways Co., and the South American Light & Power Co. (Page 340.)

Sir Francis Oppenheimer's Consular Report for the district of Frankfort deals with the proposed German Government monopoly for electric power, and announces an attempt that is to be made to utilise the motion of the tides for the production of electricity. (Page 341.)

Our correspondent at Colombo states that some extensions and improvements in the telephone system may be expected in Ceylon. Electric lighting in the capital is making only slow progress; overhead distribution has not been allowed in the suburbs, and 8d. per unit is charged for private lighting; there would seem to be a good field for metal filament lamps. (Page 341.)

It may be admitted that flame arc lamps have an unpleasant effect on the colour of ladies' complexions, but no one would aver that there is any prejudicial action upon the face that is permanent. In this respect, metal filament lamps are less fortunate, for it has been suggested, wrongly we contend, that their light contains an undue proportion of ultra-violet rays, which are said to have a deleterious action upon the eyesight. We give in this issue abstracts of two Papers, dealing with this subject, which have been published recently in a German contemporary. The experiments described in the first of these Papers merely confirm the fact that the proportion of ultra violet rays in the light from modern electric lamps has increased owing to the higher temperatures employed; but the authors of the Paper state that these rays are very dangerous to the eyesight, and they recommend the use of globes of a special glass to absorb all the ultra-violet rays. We cannot but think that these fears are very much exaggerated. It is by no means certain that the various diseases of the eyes traceable to the effect of artificial light, are mainly due to the ultra-violet rays contained in the light; indeed, there is every reason to believe that the chief cause is the frequent employment of intensely bright concentrated sources of light without any diffusing globe. It is often mentioned in support of the former hypothesis, that erythropsia, or "red sight," is very frequently developed on exposure to a bright light after the removal of the lens in cataract cases. The lens is said to absorb the ultra-violet rays, and in the absence of the lens, the rays reach the retina and cause erythropsia. Again, a case has come under our notice, in which X-rays, which may be regarded in this connection as ultra-violet rays of exceedingly short wave-length, produced cataract. The rays were being used for the treatment of lupus on the face, and as it was before the days of lead-glass screens, the eyes also were exposed to the action of the rays. There is thus every reason to be always on the look-out for the slow, but dreadful, effects of ultra-violet and other invisible rays. However, it has yet to be demonstrated that we have anything to fear, in this direction, from the influence of our commercial illuminants; indeed, in the second Paper which we abstract, some experiments are described by which it is conclusively proved that, on the whole, the proportion of ultra-violet rays in the light from artificial sources is less than that in daylight. As the same author mentions, there is much more chance of harmful effects from the use of concentrated light sources, such as the naked arc or metal filament, with their high intrinsic brilliancy. The pupil of the eye automatically adjusts itself by a reflex action to the average illumination of the field of view, and when one or more concentrated, and intensely brilliant, points of light are viewed on a more or less dark background, fatigue of the eyes is soon produced. If the light is well diffused, and no rays of a brilliancy much over the average are allowed to impinge on the retina, artificial light will cause fatigue of the eyes no sooner than daylight. Arc lamps should never be used for interior illumination without diffusing globes, and now that the increased efficiency of the metal filament lamp has enabled us to obtain our light at a cheaper rate, it will certainly be of advantage to employ frosted bulbs, adequate shades, or holophane globes, sacrificing a small amount of light in order to prevent the access of the direct rays of high intensity into the eye. Indirect illumination by reflected light is, of course, the ideal, but with the present prices of electrical energy this may be considered to be too extravagant, although it will possibly be the accepted method of illuminating interiors a few decades hence.

In conclusion, we may mention two examples of the harmful influence of strong light. The sudden and intense glare produced by a heavy short-circuit produces that painful affection of the eyes known as retinal asthenopia, accompanied by conjunctivitis or inflammation of the eyes, which may last for a month or more. It is practically certain, however, that these affections are due, not to the ultra-violet rays in the light, but to the inability of the pupil to contract sufficiently quickly, and thus reduce the intensity of the light rays impinging on the sensitive retina. The duration of such a short-circuit is often only a fraction of a second, and it is inconceivable that the ultra-violet

Digitized by Google

rays can have any influence, as the effect of such rays is a function of the time of exposure. The other example is that of "glass-blowers' cataract," which is generally attributed to the great heat. It is probable, however, that this is also due to the frequent sudden exposures of the eye to the brilliant light of the furnace.

The Liverpool runaway car accident, which occurred last Friday, has certain unusual features about it, as will be seen from the explanation which we publish from an official source. The account given by the driver is a credible explanation of the occurrence, and includes the admission that the brakes were in good order. The Liverpool practice is to fit cars with the rheostatic-electric and hand-wheel brakes, and much attention has been paid there to the correct handling of this combination, one which has certain potentialities of danger if used unintelligently. According to the driver, the car descended the slope approaching the scene of the mishap on the electric brake, at a safe speed, and should have been stopped at a Board of Trade stop just before reaching it. This necessitated the application of the hand brake, as an electric brake will not hold a car stationary on a descent. The driver putting on the brake failed to put the pawl into the ratchet wheel at the bottom of the brake spindle, and the handle flew back, striking him a severe blow on the arm, disabling it for a moment. Unfortunately, a van was on the track, or drew on to the track, a few yards ahead, and, before the motor man recovered, the car struck the van, and, being on a curve, overturned. The driver is said to be an experienced man of excellent character, and as his story will be minutely investigated at the Board of Trade inquiry, we need not inquire into some minor points, but can accept it as substantially correct. It serves as a pointed reminder of the importance of the continuous physical and mental fitness of the men conducting tramway and similar services to the security of traffic. The very temporary disablement of a man in this case brought about an accident, which under unfavourable conditions might have been a disaster. What a knock on the elbow did, a passing dizziness or faintness may do just as completely. The importance of frequent medical examination of the men is thus, curiously enough, enforced by an occurrence in which physical disability was produced by a purely external cause. Temporary absence of mind would be an equally serious danger with physical disablement, but it is fortunately of rare occurrence among tramway drivers and men in similar occupations. It probably gets detected, when it is habitual, before the men are put into responsible positions.

The engineer knows how dangerous it is to generalise from particular cases, and we need hardly warn him therefore that, although the Acton electricity undertaking, in which power is bought in bulk from a company, and distributed by the Local Authority, has proved itself a financial failure, it would be far from correct to assume that this method of operation is inefficient, and that it is not suitable in the case of small supply districts similarly situated. From a short analysis of the accounts, which we publish on another page, it will be seen that the chief cause of the large deficits that have been recorded since the commencement of supply, about three years ago, has been the enormous capital expenditure, and the consequent large sums that have had to be paid yearly as interest and sinking fund. The total capital expenditure up to date has been equivalent to just over £200 per kilowatt of maximum demand, which would be a very large figure for a station with its own generating plant, and is, of course, enormous for a sub-station and distributing network. It may be contended that this embraces certain sums expended on consumers' installations and on public lamps, but, even deducting these items, the residue still amounts to £191 per kw. of maximum demand. It is thus seen that the circumstances at Acton have been peculiar, and can hardly be used as an argument against the generation of electricity at large power houses and its distribution from sub-stations in smaller areas, instead of the erection of small independent generating stations. It is more reasonable to argue that had Acton built its own generating station on the same lavish scale of expenditure as it has bestowed on its sub-station and distributing network, the results there would have been even more disastrous.

OBITUARY

Henri Becquerel.

In the death of Henri Becquerel, at the age of 56, just reported from Paris, we have lost one of our greatest physicists. Although it is to his pupils, the Curies, that the discovery of radium is due, this discovery was only made in carrying out a systematic research to investigate further the cause of the invisible rays which Becquerel had found to be emitted by certain compounds of uranium. His announcement that photographic plates enclosed in a light-tight box with uranium salts were acted upon actinically was at first received with a considerable amount of scepticism, but it was this that formed the basis of the whole enormous field of research that has been opened up by the realisation of the existence of radio-active bodies. Up to the present no practical application has yet been made from these researches, but if the direct production of artificial light on a commercial scale ever becomes possible, it may be expected to be an outcome of Becquerel's work.

CORRESPONDENCE

THE NEW BUILDING FOR THE INSTITUTION OF ELECTRICAL ENGINEERS.

To the Editor of Electrical Engineering.

Sir,—In the report of the special general meeting which has just been circulated, it is stated that "the resolution (to confirm the action of the Council) was put and carried unanimously." This is incorrect.

No word in favour of the scheme came from anyone but the Council and those associated with them. All the other members who spoke, strongly opposed it. An amendment was finally put, which was stated by the Council to be a direct negative. As such, it was voted on. What the result would have been without the votes of the members and ex-members of Council it is hard to say, but, as it was, it was lost by a considerable number. The substantive motion was then immediately put; and the minority, seeing themselves outvoted, let it go *nem. con.* as being a mere matter of form.

The purchase looks a fairly good speculation, and we all hope it will be; but good or bad, the Council must take the whole responsibility on their own shoulders, and not try to relieve themselves of it by "unanimous" confirmation from the body of members, or even of the tiny proportion present at the meeting.

One of the Minority.

REVIEWS OF BOOKS

Principles of Direct Current Electrical Engineering. By James R. Barr. 543 pp. 8¼ ins. by 5½ ins. 294 illustrations. (London: Whittaker & Co.) 10s.

A NUMBER of lecturers in electrical engineering have endeavoured, with more or less success, to supply the want of a really suitable text-book to be used by the students attending their lectures. The tendency has, however, been in many cases for such manuals to be practically nothing else than the lectures themselves written out, with the result that, although possibly welcomed by students irregular in their attendances or too lazy to take notes, they fail in their proper object of being supplementary to the lectures themselves. A work of this nature should not attempt to be a self-contained treatise which will do away with all class-room and laboratory teaching, but to provide the student with reminders and explanations of what he hears and sees, and to contain supplementary information which he will require for reference embodied in tables, diagrams, and letterpress. Mr. J. R. Barr, of the Heriot-Watt College, Edinburgh, has, we think, kept these objects well in view in the work before us, which is admittedly based on his lectures to second-year students, and is intended, quoting the preface, to bridge the gap between the several elementary manuals and many excellent works on specialised branches of the subject.

The author assumes a certain preliminary knowledge and intelligence in his readers, and it is a relief to find that he plunges at once into electromagnetic units without troubling us first with the vagaries of pith balls and gold-leaf electroscopes. After the ideas of current and magnetisation of iron are dealt with, there is a long section on measuring instruments, and actual modern forms of apparatus are dealt with; the space is not wasted on historical reminiscences of the tangent galvanometer, and other such old friends of our youth. The illustrations are for the most part diagrammatic, although actual apparatus is usually represented, and anything of the nature of the instrument-makers' catalogue is rigidly excluded. The succeeding chapters on storage batteries and electric lighting are equally practical. Metal filament lamps are dealt with, but apparently this part of the book went to press before the now familiar tungsten lamp was brought out, as only the tantalum, and the practically obsolete osmium lamps are mentioned. The arc lamp section is fairly up to date, and photometry is treated in a much more practical manner than is usual in educational works. There is also a great deal of a thoroughly practical nature in the section of underground and aërial conductors, both as regards the insulation and laying of cables and the construction of pole lines. The chapters on the dynamo, which commence about half-way through the book, bear the same character in their treatment, and more attention is given than usual to the mechanical construction of machines. The complicated subject of commutation is clearly handled, and the effects of commutating poles and compensating windings are fully dealt with. The latter part of the book includes portions treating of motors, boosters, motor-starters, and switchgear for continuous current stations. It may be suggested that the arrangement would have been improved by incorporating earlier in the scheme part of a chapter on losses, efficiency, and testing, which is given near the end, in order that the reader should be familiar with the thermal limitations to the output of machines before considering the limits imposed by commutation and flashing over—but on the whole the arrangement, as well as the proportions in which the theoretical and the practical are blended, are excellent.

Electrical Engineering. By W. Slingo and A. Brooker. 832 pp. 389 illustrations. 5 ins. by 7½ ins. (Longmans, Green & Co.) 12s. 6d.

IN this well-known text-book, which has passed through many editions since its first appearance in 1890, the authors originally set themselves the ambitious task of covering the whole field of electrical engineering in a manner at the same time suitable to the technical college pupil and (to quote the preface to the first edition), "also to those who, having little or no electrical knowledge, have under their supervision various kinds of electrical machinery." This was no doubt easier in 1890 than now, but in succeeding editions the revisers (Mr. Slingo and Mr. T. F. Wall) have made brave, if only partially successful, attempts to pursue this ideal, and to keep pace with the strides that electrical engineering has made since then in all its branches.

A good deal relating to thoroughly modern practice has been put in, but we are sorry to have to say that the result is somewhat of a patchwork, as, naturally enough perhaps, the authors have been loath to expunge the earlier work even where it relates to matters obviously of historical rather than present day interest. We do not object to obsolete machines being referred to briefly when they have a direct bearing upon the line of development which has led to present design, but to denote almost equal space to an ancient de Meritens magneto alternator, and to a modern 3,000 kw. Dick, Kerr turbo-alternator, shows a great lack of sense of proportion. There is also, from the same cause, an incongruous mixture of the elementary and the advanced; for example, after the refinements of hystersis cycles have been gone into, it is suddenly remembered that the reader is supposed not to have been to school, and about two pages are taken up explaining what the sine of an angle is. Nor are the recent additions to the book always quite accurate. It is incorrect, for example, to say, in speaking of turbo-generators, that "the temperature at which high-speed machines are worked is higher than in the case of slow-speed machines." What is meant is that more complete methods of ventilation are required in order to keep within the same limits of temperature.

There is, however, a great deal that is excellent in the more recent additions. The lamp section has been brought up to date by the inclusion of recent work that has been done in the standardisation of carbon filament lamps, although it is not too much to say that in a few years these too will be almost as obsolete as the de Meritens are lighter. Numerous results of tests of the tantalum lamp are given, but we have searched the index in vain for a reference to the Osram or other form of tungsten lamp.

Some Quick and Easy Methods of Calculating: A Simple Explanation of the Theory and Use of the Slide Rule, &c. By R. G. Blaine. Third edition. (London: E. and F. N. Spon.) 2s. 6d

SINCE *Punch's* famous joke of the curate's egg, many reviewers have applied the useful quotation, "Parts of it are excellent," to many books, but whether the readers for whom this book is intended may be trusted to have the curate's power of discriminating between the good and the bad is doubtful. In fact, the author is at great pains to make his book suitable for users whose knowledge of arithmetical computation is very elementary. In some of his simple examples he would almost appear to suggest the slide rule as a substitute for the multiplication table. The tendency of the book is, we fear, to produce "slaves of the slide rule"; what is wanted is a clearer knowledge and mastery of it as a brain-saving tool. The position of the decimal point, in the final figures of a slide-rule operation, is the subject of many involved and, let us confess, tedious passages, requiring, besides, jottings on paper. The fate of most of these rules is

Digitized by Google

that they are forgotten, and that the engineer applies the plain law of common-sense as a substitute. On the other hand, there is hardly an owner of a slide rule who would fail to benefit by a perusal of Mr. Blaine's book. Incidentally we may deplore a surprising dearth of the definite article, and why, oh why, the terrible word "delogarize"!

Elektrotechnische Messkunde zugleich Leitfaden für das Elektrotechnische Praktikum. By A. Königswerther. 5¾ in. by 8¾ in. 172 illustrations. (Hanover: Dr. Max Jänecke.) M. 4.80.

This book is the second volume of a series entitled "Grundriss der Elektrotechnik." The first volume was by the same author, and was entitled "Physikalische Grundlagen der Gleich- und Wechselstromtechnik." The present volume is intended as a text-book for the use of students, and treats with the various measuring instruments, both for laboratory and general use, and with the different methods of carrying out electrical measurements. Apparatus used in testing, such as standard resistances and condensers, is also included. The descriptions are very concise, and no unnecessary details or modifications are dealt with. The sketches are well chosen, so as to show only the principle of the instrument in question, and only a very few outside views are given. The subject of photometry, which will be dealt with in a future volume of the series, is not included in this one. The last chapter includes methods of measuring phase differences and short descriptions of three modern phase-meters. The numerous references to works dealing more fully with the various subjects should be of great use to the reader who has a technical library within reach.

Hand-Book of Farm Buildings, Ponds, &c., and their Appurtenances. By Thomas Winder. With a chapter on "The Application of Electricity to Farming and Agriculture. By J. W. Beauchamp. 171 pp. 5¼ in. by 8½ in. 106 illustrations. (Sheffield: Pawson & Brailsford.)

The main portion of this book deals with the design and construction of farm buildings, and contains, besides a good collection of scale drawings and photographs of modern farm buildings, several interesting photographs of old types. That portion of the book which concerns us, however, consists of seven pages of printed matter, together with nine half-tone illustrations relating to the application of electricity to farming and agriculture. The author summarises what has been done in this country in this direction, and mentions a few of the advantages which are to be obtained by electrically driving cream separators, churners, chaff-cutters, and other farm apparatus. This will serve to whet the appetite of the farmer for electric power. It is to be regretted, however, that such details as the necessary horse-power required to drive individual machines, and the probable total horse-power required by a large modern farm, are missing. The application of electricity for the purpose of hastening the germination and growth of crops is only mentioned briefly, without reference to the recent developments in this direction.

Electrical Engineering in Bahia.—A British Consular report states that the tramway system of the lower city has been acquired by the Bahia Tramway, Light and Power Company. This company has been incorporated under the laws of the State of Maine, United States. It is stated that the company has been organised with the objects of acquiring, constructing, and developing tramways, and of supplying electrical power, electric light and gas in the city of Bahia and in the surrounding districts. It has purchased, as already mentioned, the tramway system which serves the lower city. This tramway system, known as Carris Electricos, consists of over 15 miles of track, worked by electrical traction; it is licensed to carry freight as well as passengers. It formerly belonged to a German company, by whom the line had been built and equipped. All rights pertaining to the tramway system were sold by the German owners to the Bahia Tramway, Light and Power Company during the year 1906. The company has also acquired, by purchase, the interests of La Compagnie d'Eclairage de Bahia, a Belgian corporation, which had acquired the exclusive right to manufacture and to sell gas and to distribute electric light and electric power in the city and suburbs of Bahia until the end of 1950. The new company hopes to be instrumental in greatly extending here the use of electric power, of electric light, and of gas—the last mentioned for cooking purposes as well as for illumination. In order to provide for the anticipated demand the company has entered into a contract with the British firm of Dick, Kerr & Co., Ltd., for increasing the existing gas plant and for installing a first-class light and power plant, to be worked by powerful gas engines. The same company has acquired valuable water-power rights in connection with the falls of the River Jequiriça, some 45 miles south of the city. The falls in question are 175 ft. in height, and it is calculated that there can be transmitted therefrom over 10,000 commercial horse-power to the city of Bahia. The company has furthermore acquired the water-power rights in connection with the falls of the River Santarem, which are situated some 60 miles to the south of the city, close to the sea coast.

SHEFFIELD CORPORATION TRAMWAYS ACCOUNTS

THE report and statement of accounts for the year ended March 25th, 1908, issued by the Tramways Committee of the Sheffield Corporation, contain information of a financial character only, with the exception of the following statistical returns. The car miles run during the year amounted to 7,065,380, as against 6,804,656 for the previous year. Over 77,500,000 passengers were carried during the year, an increase of over 3,500,000 on the corresponding figure for the previous year. The traffic receipts have increased from £276,907 to £289,744. The number of permanent employées in the Tramways Department is now 1,527. The rolling stock consists of 268 service cars and 11 water, stores, or sand cars. The total working expenses of the system amounted to 6·045d. per car mile, as compared with 5·940d. for the previous year. The increase is accounted for by increased wages paid to employées in the department.

Analysis of Expenses per Car Mile.

	Year ended Mar. 25, 1907.	Year ended Mar. 25, 1908.
Traffic expenses—	d.	d.
Salaries and wages	2·729	2·775
Cleaning cars and depot expenses	0·342	0·388
Cleaning, salting, and sanding track	0·113	0·103
Ticket check, including wages of inspectors	0·084	0·079
Uniforms	0·145	0·121
Miscellaneous	0·029	0·037
	3·442	3·503
General expenses—		
Salaries and wages	0·133	0·138
Rent, rates, and taxes	0·424	0·413
Insurance, and law expenses	0·067	0·064
Miscellaneous	0·090	0·083
	0·714	0·708
Repairs and maintenance—		
Permanent way	0·250	0·239
Electrical equipment of line	0·130	0·147
Cars	0·602	0·654
Buildings and miscellaneous	0·064	0·057
	1·046	1·097
Power expenses—		
Fuel	0·372	0·418
Salaries and wages	0·152	0·155
Oil, waste, water and stores	0·064	0·037
Repairs and maintenance	0·150	0·127
	0·738	0·737
Total costs, excluding capital charges	**5·940**	**6·045**
Capital charges—		
Interest	1·460	1·265
Income tax	0·078	0·082
Sinking fund	0·907	1·045
Renewals and special purposes funds	0·776	0·747
Total costs, including capital charges	**9·161**	**9·184**

The total working expenses amounted to £177,950, and the total receipts to £292,393, of which £289,744 was traffic receipts, and the remainder, £2,649, was the income from advertising on cars, rents, &c. Of the balance of £114,443, interest, sinking fund, and income tax absorbed £37,242, £30,753, and £2,427 respectively. The remainder of the balance, together with the interest on investments and bank interest, amounted to £47,472. This was appropriated as follows: £22,066 was transferred to the Renewals Fund; £2,000 to the Special Purposes Fund; and £873 to the Surplus Fund. The remaining £22,533 was handed over to the General District Rate. The total number of units generated amounted to 13,192,575, and the total cost of generation, 0·668d. per unit, of which 0·394d. was accounted

Digitized by Google

for by fuel, stores, wages, &c., and the remainder by a proportion of the capital charges. The percentage of the working expenses to the total receipts was 60·86 per cent. The following figures are also of interest: Total number of units used for cars, 12,188,861; number of units used per car mile, 1·725; average traffic revenue per car mile, 9·842d.; and the average total revenue per car mile, 10·049d.

THE ACTON ELECTRICITY UNDERTAKING

WE referred briefly in our last issue to the comparatively heavy deficit shown in the electricity supply accounts of the Acton Urban District Council, in spite of the fact that this undertaking has merely the simple task to perform of buying its electricity in bulk, converting it to low pressure, and retailing it to the consumer.

Electrical energy is bought from the Metropolitan Electric Supply Co., Ltd., at an average price of 1·14d. per unit (847,916 units for £4,021). The number of units sold during the year 1907-8 amounted to 511,212. As the number of units generated at the low tension terminals was 645,335, the all-year-round efficiency of the converting plant was 76·1 per cent. Of the balance, 85,720 units were used in the sub-station, and 48,403 represent the distribution losses, and it is seen that the overall efficiency between high tension 'bus-bars and consumers' terminals is 60·3 per cent. Although this may not seem a very low efficiency, it must be noted that it means that about 66 per cent. more energy has had to be paid for than is actually sold. Still, even when this percentage is added, the cost would be still under 2d. per unit, and the average selling price was 3·88d. per unit (511,212 units for £8,260).

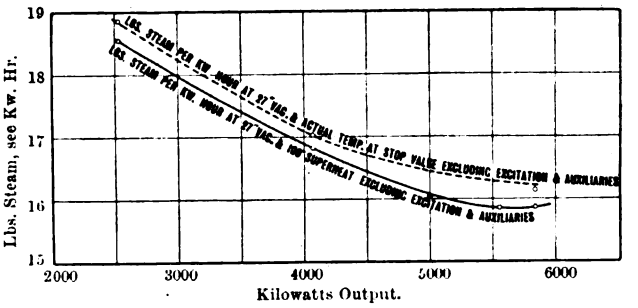
This margin, however, has not been nearly sufficient to meet the sub-station, distribution, and management costs, and the capital charges. The last-mentioned have been particularly large. The total capital expenditure has been £66,647, representing £201 per kw. of maximum demand (332 kw.). Part of this sum, it is true, has been spent on consumers' installations and public lamps, but if allowance is made for this, the balance is still £63,501, or £191 per kw., which is enormously high when it is remembered that it has only been for the converting plant and distributing network. The interest and sinking fund charges have amounted to £3,993, or 1·87d. per unit sold. Adding wages, repairs, and renewals, rents, rates, and taxes, management expenses, and other miscellaneous expenditure, the total expenditure for the year, exclusive of the cost of the energy bought "in bulk," comes out to £8,007. This includes a sum of £538 for installations on consumers' premises and meters, against which is an item of £607 on the revenue side, representing "amounts recoverable for sale of lamps and apparatus and work executed." It also includes a sum of £367 for maintenance and repairs of arc lamps, for which the Council is well paid, as 4d. per unit is charged for public lighting. If we deduct the two items of £538 and £367 from the total of £8,007, we get £7,102 as the cost of converting and distributing the 511,212 units sold, including capital charges, and this works out to 3·34d. per unit sold.

The total costs per unit sold, including the cost of the bought units, as well as the capital charges, is therefore 5·23d.

The average selling price, as we have said, was 3·88d. per unit, but to compare it with the total costs as given above, we must deduct from the revenue the cost of arc lamp maintenance, as this has already been deducted from the expenditure side, and is paid for out of the 4d. per unit paid for arc lighting. The average price obtained per unit thus works out to £7,893 divided by 511,212, *i.e.*, 3·70d., and there is thus a loss of over 1½d. per unit sold.

TESTS ON A 6,000 KW. TURBO-ALTERNATOR

WE published last week the results of some tests of a 5,000-6,000 kw. Willans-Siemens turbo-alternator which has been running since last May at the Manchester Corporation electricity works in Stuart Street. This week we are able to give the actual curve of steam consumption for the range of loads per



2,000 to 6,000 kw. It will be seen that the actual readings have been corrected to apply to a superheat of 100° F., and a vacuum of 27 in. The consumptions do not include the energy used for driving the air-pump and circulating pump of the condensing plant, nor the excitation losses. The lowest consumption was 15·84 lb. of steam per unit when the machine was developing 5,650 kw.

Wireless Telephony and Telegraphy.—The American wireless telegraphy expert, Dr. Lee de Forrest, has very hopeful views as to the future of wireless telephony. He announces that the French Government has consented to allow him to use the Eiffel Tower for the purpose of establishing wireless telephonic communication between Paris and New York. For the same purpose, a contract was signed last week between the American De Forrest Co. and the Metropolitan Life Insurance Co., providing for the use of the 700-ft. high tower of the latter company's new building in Madison Square. Dr. De Forrest estimates that the range of his telephonic apparatus in its present state is only 1,000 miles; but he fully expects that certain improvements, which he is now working at, will render wireless telephonic communication between Paris and New York possible within two years. The installation on the Metropolitan tower will, it is expected, be ready for operation at the end of this year. By the use of unusually long wave-lengths, Dr. De Forrest hopes to prevent interference of the service by other wireless messages.

Some further particulars with regard to the experiments which are being carried on in France by some naval engineers have been published in the *Matin*. The Poulsen transmitter, with one carbon and one water-cooled copper electrode, is used at the Eiffel Tower station, and the electrolytic detector of Captain Ferrié is employed for receiving. It is stated that the power necessary to keep up wireless telephonic communication between Paris and Dieppe does not exceed four kilowatts. We understand from the Amalgamated Radio-Telegraph Co., Ltd., who are the owners of the British & Continental rights of the Poulsen wireless telephone patents, that they have not granted any licences to any other firms, either in this country or on the Continent. They also inform us that the Danish group, who still retain the American rights of the Poulsen patent, have not granted any licences to Dr. De Forrest or any other company.

As a result of the successful experiments in wireless telephony conducted by Prof. Majorana, head of the technical department of the Italian Ministry of Posts and Telegraphs, at Monte-Mario, the professor is installing apparatus to enable communication to be effected between Rome and Sardinia. The success of the experiments is attributed partly to the use of a special form of microphone invented by Prof. Majorana, in which running water is said to occupy a prominent part.

According to the *Electrical World*, communication has been established between Iquitos, on the river Amazon, and Lima, partly by wireless telegraphy. The means of connection from Lima to Puerto Bermudez is an ordinary wire telegraph line, but from Puerto Bermudez to Iquitos, the distance of about 1,000 km., including long stretches of primeval forest, is bridged by wireless. The original intention of the Peruvian Government to connect Iquitos with the outside world by wire was given up on account of the immense difficulty and cost. The Telefunken Co., putting in the system, succeeded in establishing the service within two years. The expense of installation, which was about £40,000, was defrayed by the Peruvian Government.

THE EFFECT OF METAL FILAMENT AND ARC LAMPS ON THE EYES

IT has long been suspected that "snow-blindness," or that affection of the eyes produced by long exposure to a strong light, such as exists in snow-clad regions, is partly due to the action of ultra-violet light reflected from the surface of the snow; and an affection known as *Ophthalmia electrica*, caused by direct exposure of the eyes to the rays of the electric arc, is sometimes considered to be identical with "snow-blindness." The proportion of ultra-violet rays in the light emitted by our artificial illuminants has necessarily increased with the increase in the temperature of the illuminating gas or body, and it has been suggested that the light emitted by the new metal filament lamps, and also that given out by those arc lamps which work at a high temperature, may have a very harmful influence on the human eye.

A recent issue of the *Elektrotechnische Zeitschrift* contains a Paper on the subject, which was read by Drs. F. Schanz and C. Stockhausen, before the Erfurt Congress of the Verband Deutscher Elektrotechniker in June last. Some experiments, carried out at the Technical University in Dresden, showed that, of the various types of electrical illuminants, the mercury-vapour lamp with quartz globe emitted the largest proportion of ultra-violet rays. The naked arc lamp came second, and the naked Nernst lamp third. The glass globe essential to all filament lamps and enclosed arc lamps, was found to absorb all ultra-violet rays of wave-lengths shorter than about 300 $\mu\mu$, but rays of wave-lengths longer than this have a distinctly harmful influence on the eyes. The authors describe the various affections of the eyes which are the results of exposure to ultra-violet light, and state that, in their opinion, the question of the protection of the eyes from the harmful influence exerted by artificial light sources should be seriously considered. Ordinary coloured glass globes, unless of such density as to reduce seriously the intensity of the light, are useless for this purpose, but after careful experiments, the authors have produced a glass (which they term "Euphos" glass) which, though only faintly yellow-green in colour, effectively cuts off, or rather absorbs, all the ultra-violet rays, without absorbing more than from 3 to 5 per cent. of the light emitted. They have produced glasses of slightly different compositions for different light sources; and the composition is such, that in each case the ultra-violet rays are totally absorbed with the least possible absorption of light rays in the visible spectrum. Photographs of the spectrum emitted by an arc lamp showed that an ordinary 1 mm. globe absorbed all rays shorter than 300 $\mu\mu$; but that an 0·8 mm. "Euphos" globe absorbed all the ultra-violet rays, leaving only the visible spectrum. Photographs of the spectrum of metal-filament and Nernst lamps showed the same effects.

An article by Dr. Voege, of the State Physical Laboratory at Hamburg, in the same issue of the *Elektrotechnische Zeitschrift*, describes the results of some experiments made to determine the relative proportion of ultra-violet rays in daylight and artificial light respectively. The author states that, although the experiments of Drs. Schanz and Stockhausen showed that modern electric lamps emit a larger proportion of ultra-violet rays for a given amount of light than do the older forms of illuminants, owing to the higher working temperature, there was no evidence to show that the proportion is higher than that for daylight, or direct sunlight.

The experiments conducted by Dr. Voege were divided into two series. The first series were made to determine the proportion of ultra-violet rays reflected from a white matt reflecting surface illuminated by sun or daylight and artificial light respectively. Two halves of a photographic plate were exposed respectively to the light reflected from two such surfaces illuminated from the two lights to be compared, after the distance of the artificial light source had been so adjusted that the two surfaces were *equally illuminated* as judged by the eye. All lenses were of quartz, so that no ultra-violet rays should be absorbed, and a screen or filter, consisting of a quartz vessel containing a solution of nitroso-dimethylanilin, was interposed between the illuminated surfaces and the plate. This filter absorbs all the light rays of the visible spectrum, but is transparent to the ultra-violet rays. The actinic rays of the visible spectrum are also absorbed by this filter, so that any chemical change on the surface of the plate would be due to ultra-violet rays only.

Experiments made with this apparatus proved that *for a given illumination* of the white surfaces, the proportion of ultra-violet rays in the reflected light was nearly always greater in the case of daylight. Even in the case of the mercury-vapour lamp with quartz globe, the difference, though pronounced when the comparison was made with light from a white clouded sky, was hardly distinguishable when the light from a clear blue sky was used. From these experiments the author concludes that for equal illumination, the light from artificial sources contains generally a smaller proportion of ultra-violet rays than does ordinary daylight, and consequently cannot be harmful to the eyes on this account. Certain arc lamps without globes and the quartz-globe mercury-vapour lamps do certainly provide a light richer in ultra-violet rays than sunlight, but the difference is only slight, and the ordinary glass outer globes used in conjunction with these lamps would certainly absorb the excess.

The second series of experiments were made with the object of comparing the proportion of ultra-violet rays in light received direct from an artificial source of light, and in that reflected from the sun by a polished metal mirror. Photographic plates were exposed for a given time through a spectrometer to lights from various sources in this way, and the results proved conclusively that the spectrum from sunlight extended much further into the ultra-violet region than any other. The lamps were placed at distances from the spectrometer, which were assumed to be the distances usual between the eyes and the respective light sources, for example, one metre for the arc lamp and 40 to 60 cm. for a filament lamp. The intensity of the ultra-violet rays was also found to be greatest in the case of sunlight. Other experiments showed that the reflected sunlight from a plaster or white-washed wall is stronger than the direct rays from the translucent globe of a 2,000 candle-power flame arc lamp at a distance of two metres, both as regards the extension of the spectrum into the ultra-violet region, and the intensity of the rays, both visible and invisible.

The fact that an arc lamp is apparently so much more brilliant than a sunlit surface, and is even unpleasant to look at directly, is explained by the author as being due to the unequal intensity of the light in the field of view in the former case. We have, in the author's opinion, much more to fear from the influence of unequal illumination than from ultra-violet rays in the light itself. The fear of harmful injury to the eyes from the influence of ultra-violet rays is consequently shown to be unfounded by the results of the above experiments, as if the proportions which obtain for daylight are not departed from to any considerable extent, no prejudicial action on the eyes need be expected.

The unequal illumination generally produced by artificial lighting is, however, a serious matter, and worthy of consideration. The new metal-filament lamps should really never be directly visible to the eye on account of the high intrinsic brilliancy of the filaments. Frosted globes surrounding a group of lamps and producing a uniform diffused illumination are to be recommended, and, of course, where possible, an indirect system of illumination is to be preferred, although this is uneconomical, owing to the amount of light lost by the absorption of the reflecting surfaces.

Electric Traction in the Simplon Tunnel.—The period of two years, after which the electrical equipment of the Simplon Tunnel was to be either removed by Brown Boveri & Co., or purchased by the Administration of the Swiss Railways, elapsed on June 1st last. The electrical equipment has proved so satisfactory that it has been purchased. It will be remembered that the firm of Brown Boveri & Co. undertook to provide the electrical plant at its own risks, and to restore the tunnel for steam traction if, after a period of two years, it was found that steam traction would be preferable. It is stated that the experiment, in spite of the sale of the equipment, has been a source of considerable loss to the company.

Telegraph Traffic.—Persian telegraphic communication has suffered temporary interruption, the line to Tauris and the province of Azerbaidjan having failed; but messages for these places are being sent *via* Indo.—The submarine cable between Cadiz and Teneriffe, which was previously reported as working badly, ceased working on 20th inst.—Telegrams to and from Brazil, Argentine Republic, Paraguay, and Uruguay, which under normal conditions went *via* Talisman, are now being forwarded by the Brest-Dakar cable without change of rates, and are sent "*via* Talisman" beyond. This route indication must appear in the preamble of the message.—We are also in a position to state that the line between Rome and Pera was restored on 21st inst. The delay in the repair of the Kwandang-Menado cable is due to the repairing steamer *Patrol* having run aground. The c.s. *Recorder* has gone to her assistance.—Communication with Nantucket has been restored, and messages by wireless can now again be sent by this route to Atlantic Liners.—The cable-repairing steamers *Relay* and *Mexican*, owned by the Mexican Telegraph Company, are both at present at New York. The latter is up for sale.

POWER SUPPLY IN THE NORTH OF FRANCE

A DESCRIPTION has been given recently in *Le Génie Civil* of the power supply undertaking of the Société de l'Energie Electrique du Nord de la France which commenced operations last year in the important industrial district of Lille, Roubaix, and Tourcoing. This company was formed for the supply of electricity for lighting and power in the towns already mentioned and a group of surrounding places of smaller size as far as the Belgian frontier, and also to supply current to Compagnie de Tramways de Roubaix-Tourcoing and the Société l'Electrique Lille-Roubaix-Tourcoing.

The power station is in a very central position in the district served, at Wasquehal between Lille and Roubaix adjoining a branch of the Roubaix Canal. Its construction was commenced in September, 1906, and the supply was started in October, 1907, since which time the load has increased to such an extent as to necessitate extensions. A sketch plan of the site is given in Fig. 1. Communication with the railway is obtained by a special branch line crossing the canal by a bridge, and coal can be obtained either by train or from the neighbouring mines by canal. The building consists of parallel boiler and engine-rooms, constructed principally of reinforced concrete and, as is often the case, one end is permanent and the other temporary with a view to extensions. The equipment when complete will provide for an output of 25,000 kw. and will contain 40 boilers, of which 16 are now installed, and 7 turbo-generators varying in size from 1,500 kw. to 5,000 kw., of which four are already complete or in course of erection.

As already mentioned, coal can be obtained either by railway or by canal. In the former case the waggons are brought from the railway depôt over the company's own line to the works by an electric locomotive. This locomotive runs on a continuous current, 440-volt circuit, and was constructed by the firm of Hillairet Huguet. It has a weight of 5½ tons and can carry 1½ tons of ballast. A load of 30 tons can be drawn up a 1·7 per cent. gradient with a curve of about 400 ft. radius at a speed of about 1·7 mile per hour. The draw bar pull is 1 ton.

The coal arriving by water is taken from the barges moored to a special quay by a travelling jib crane provided with a grab, and deposited on the storage ground. This crane is constructed for a load of 2½ tons and has a radius of about 30 ft. with the pulley about 28 ft. from the ground. The lifting motor is rated at 28 h.p., and the slewing and travelling motors are 5 h.p. and 9 h.p. respectively. As a general rule, however, no great amount of coal is stored. The coal is taken from the storage ground to the boiler house in small trucks made in two halves, after the manner of a grab, so that the coal can be discharged below. These are filled from a hopper and are taken in trains of six to the entrance of the boiler house, where they pass over an Avery automatic integrating weigher. The top parts of the truck are then lifted bodily off by a special electrically-driven transporter, which takes them to the required point over the overhead coal bunkers and causes them to open and discharge the coal. In the event of breakdown of the transporter or repairs being required to the overhead bunker, arrangements are made so that the trucks can be taken direct to the firing floor. A further service of trucks from the basement of the boiler house returns the ashes and clinker. A section of the station is given in Fig. 2. The boiler house equipment will consist of 40 Niclausse water tube boilers, of which sixteen are already installed. These boilers are grouped in batteries of two and arranged in two rows on either side of the boiler house. Each is capable of evaporating about 110,000 lb. of water per hour and has its own 96-tube Green economiser and Niclausse superheater intercalated among the tubes. A superheat of 325°C. is available. Each boiler has about 2,000 square feet of main heating surface, 460 square feet of superheater surface and a grate area of about 62 square feet. The economisers are arranged with bypass flues, so that they can be put out of action for cleaning or inspection when required. Several systems of mechanical stoking are in experimental use, including a Bennis stoker and one of the underfeed type. Another boiler is being fitted experimentally with a Marconnet

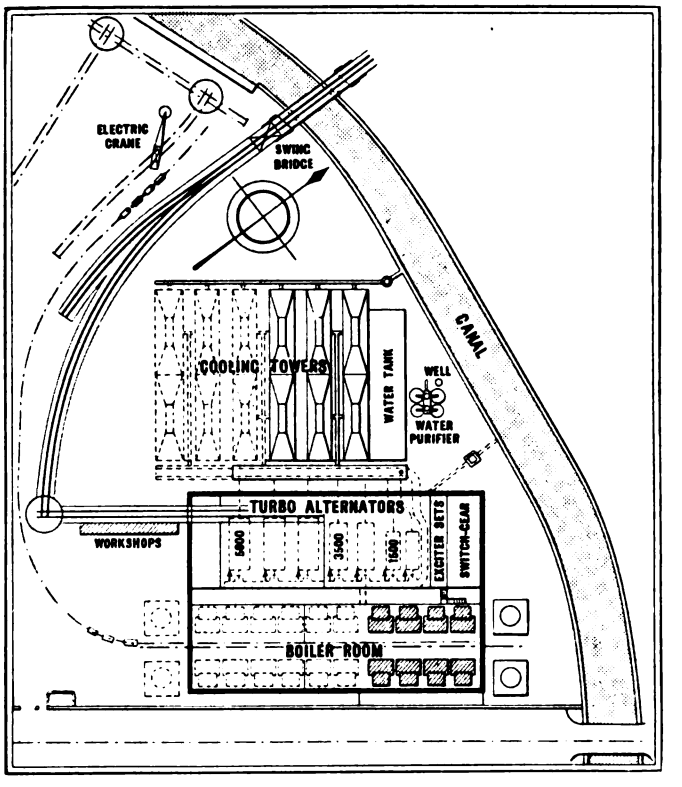

FIG. 1.—GENERAL PLAN OF SITE.

apparatus for burning low grade fuel in dust or powdered form.

The boilers can be fed either direct or through the economisers and the bad quality of the water obtainable which contains salts, such as sulphate and carbonate of soda, difficult to remove by the ordinary processes of purification, necessitates very special arrangements being provided. The boilers are divided for feeding purposes into two groups, one containing four boilers and the other the remaining 36. The small group are fed entirely from the make-up feed water which has passed through the purifier, and therefore all the soluble salts remaining in the water are concentrated in the four boilers which are very frequently cleaned. The other boilers are fed exclusively with the condensed water from the surface condensers and the steam traps. The boilers are fed by five-stage centrifugal Sülzer pumps driven at 2,800 r.p.m. by induction motors. Duplex steam-driven "Monitor" pumps are used as a stand-by.

The cooling water from the condensers passes through a group of Balke wooden cooling towers. The total amount of water evaporated when an output of 20,000 kw. is being given will amount to about 350,000 lb. per hour, and to condense this quantity of steam about 175,000 gallons of water per hour are required. For

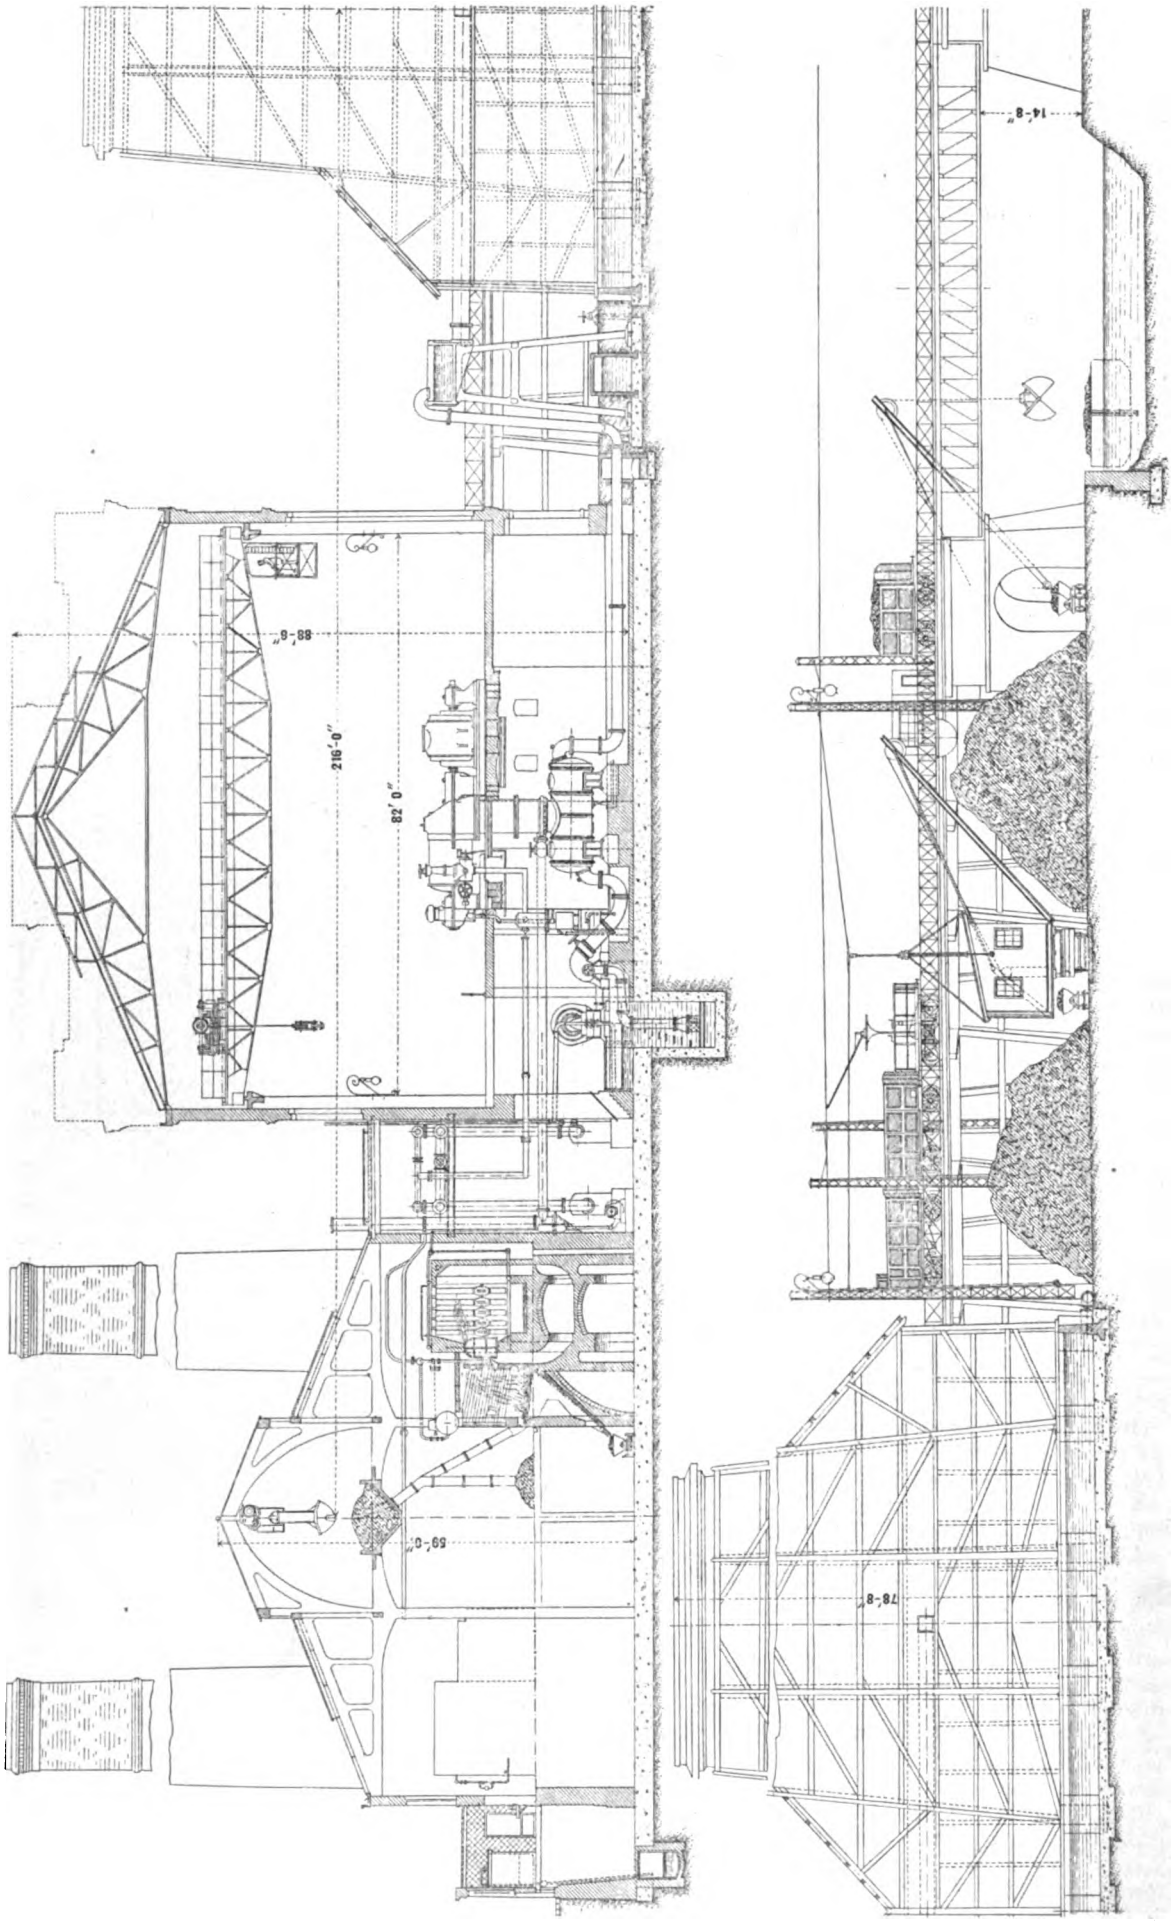

Fig. 2.—Section of Power Station and Elevation, showing Coal Handling Arrangements.

Digitized by Google

cooling this water six towers, each capable of dealing with 32,000 gallons per hour, will be provided, of which three have already been erected. The make-up water for this purpose can be taken either from a well nearly 500 ft. deep or from the canal. In order to avoid corrosion of the condenser tubes this water is passed through a purifier on the Declercq and Verbiège system, capable of dealing with some 2,450 gallons per hour, in which the calcium carbonate is precipitated in the presence of the deposit accumulated from the water that has previously passed through, which renders the reaction more rapid. The water is carried to the top of the cooling towers by centrifugal pumps driven directly by three-phase induction motors.

The engine room is of ample proportions, and is served by a 30-ton electric travelling crane of 32 ft. span. The arrangement of the various generating sets which will compose the equipment is shown in Fig 2. The turbines at present installed are of the Brown-Boveri-Parsons type, running at 1,500 r.p.m and designed to work at a steam pressure of 200 lb. per. square inch and superheated up to 300°C. The two first sets have an output of 2,250 k.v.a. at a power factor of 0·8 (1,800 kw.), and two further sets for 4,350 k.v.a. 3,500 kw.) are in course of erection. As will be seen from Fig. 3, which gives a section of the engine room, each set has its condensing plant directly beneath it. Automatic valves permitting of an atmospheric exhaust when the vacuum is impaired are provided. The following are the guarantees for coal consumption:—Maximum load, 15·3 lb. per kw.-hour; normal load, 15·7 lb., and half-load, 18·5 lb. The generators are guaranteed to give their maximum output per 24 hours without the temperature rise exceeding 55°C., or their normal output without exceeding 45°C. The next instalment of plant to be erected will be two 5,000 kw. sets.

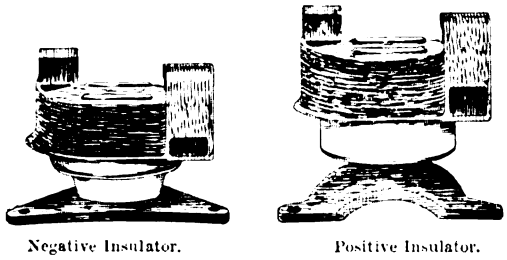
The alternators are wound for 10,000 units 50 cycles and are excited by a 210-volt exciter driven by a 300-volt alternating motor. Current is taken from the alternators to two sets of ring bus-bars, either of which can be completely isolated if necessary. These bars are of sufficient section to carry the whole ultimate output of the station (25,000 kw.), and are protected by water jet surge preventors. Current for service purposes about the station is obtained from a set of step-down transformers fed from the main bus-bars, and supplying a 300-volt circuit from which current is taken by the excitation motor generators and auxiliary motors already mentioned. Another supply of continuous current, from which the excitation can be taken if necessary, is provided by a battery which can be charged by a separate steam-driven high-speed continuous-current dynamo. This battery has a capacity of 120 ampere-hours, and can be used for station lighting in cases of emergency. The station lighting is, however, usually supplied from a 100 k.v.a. Westinghouse rotary converter, which also supplies at 440 units the crane, locomotive and transporter, which have already been spoken of in connection with the coal-conveying plant.

The switchgear is arranged at one end of the engine-room on galleries of reinforced concrete forming fine floors. In the basement is placed the battery and the transformers, and on the next floor are the 10,000-volt bus-bars and high-tension switches, surge preventers, &c. Above this is the operating gallery, whereon are placed the desk-type control panels for the generators and the boards for the auxiliary station service, exciting circuits, &c. The feeder switches, &c., for the underground feeders are situated on the next floor above, and the apparatus connected with the overload feeders occupies the top floor. A panel is provided on the operating gallery with measuring instruments for observing and recording the whole output of the station.

The outgoing feeders are composed partly of cables and partly of overhead lines leading to various transformer sub-stations. The four main sub-stations for the supply of tramways are at Roubaix, Tourcoing, La Madeleine, and Leers; each of these contains five 240 kw. Westinghouse rotary converters, and the necessary transformers and switchgear.

CONDUCTOR RAIL LEAKAGE ON THE LONDON UNDERGROUND RAILWAYS

A PAPER, entitled "Conductor Rail Measurements," was read by Mr. S. B. Fortenbaugh at the Summer Convention of the American Institute of Electrical Engineers, in which are included some results of tests of leakage, &c., on the conductor rails of some of the underground electric railways of London. The Paper commenced with a few notes on the differences between the equipment of the District Railway and the new Tube lines. As is well known, "third" and "fourth" rails are employed on all the railways of this group. Both the conductor rails are of low carbon steel, and are supported on stoneware



Negative Insulator. Positive Insulator.

FIG. 1.—INSULATORS USED ON DISTRICT RAILWAY.

insulators. The insulators used in supporting the positive (outside) and negative (centre) conductor rails are essentially of the same design on the individual roads, the top of the positive insulator being 1·5 in. higher than the negative. A malleable-iron cap and base is used on the District Railway insulators, the difference in height of the positive and negative insulator being partly in the depth of the insulation and partly in the design of the base. The form of the insulators on the District Railway is shown in Fig. 1.

No base or cap is used with any of the insulators on the Tube railways. The top of the positive conductor rail is 10 in. and 10·5 in. above the top of the sleepers on the District and Tube railways respectively.

Fig. 2 gives full details of the arrangement of the track and conductor rails, including some additional sections to those given in Mr. Fortenbaugh's Paper.

An extended series of preliminary measurements and tests were made on the Hounslow and Putney section of the District Railway early in 1905, with a view of trying to account for the comparatively low insulation resistance of the negative conductor rail. These tests were made during the constructional period; with the regular steam trains in daily commercial service, and the insulation of the conductor rails was therefore more or less of a variable quantity and subject to the temporary changes and conditions incidental to such work. The positive (outside) conductor rail, particularly at the stations, was heavily coated with grease from the steam trains, and this, together with loose ballast dirt, &c., made it practically impossible to maintain good insulation during these tests. The results were therefore somewhat erratic, but plainly indicated the existence of the peculiar phenomena afterwards observed under more favourable conditions on the Tube railways. Subsequent tests of the voltage between the earth and the positive and negative rails respectively were made after the trains had been running about six months, and with a line voltage of 580 this was found to vary between the limits of 540 volts for the positive rail, and 40 volts for the negative rail in "very fine" weather, to 478 and 102 volts respectively in "very wet" weather.

The tests on the Baker Street and Waterloo Railway, like

Digitized by Google

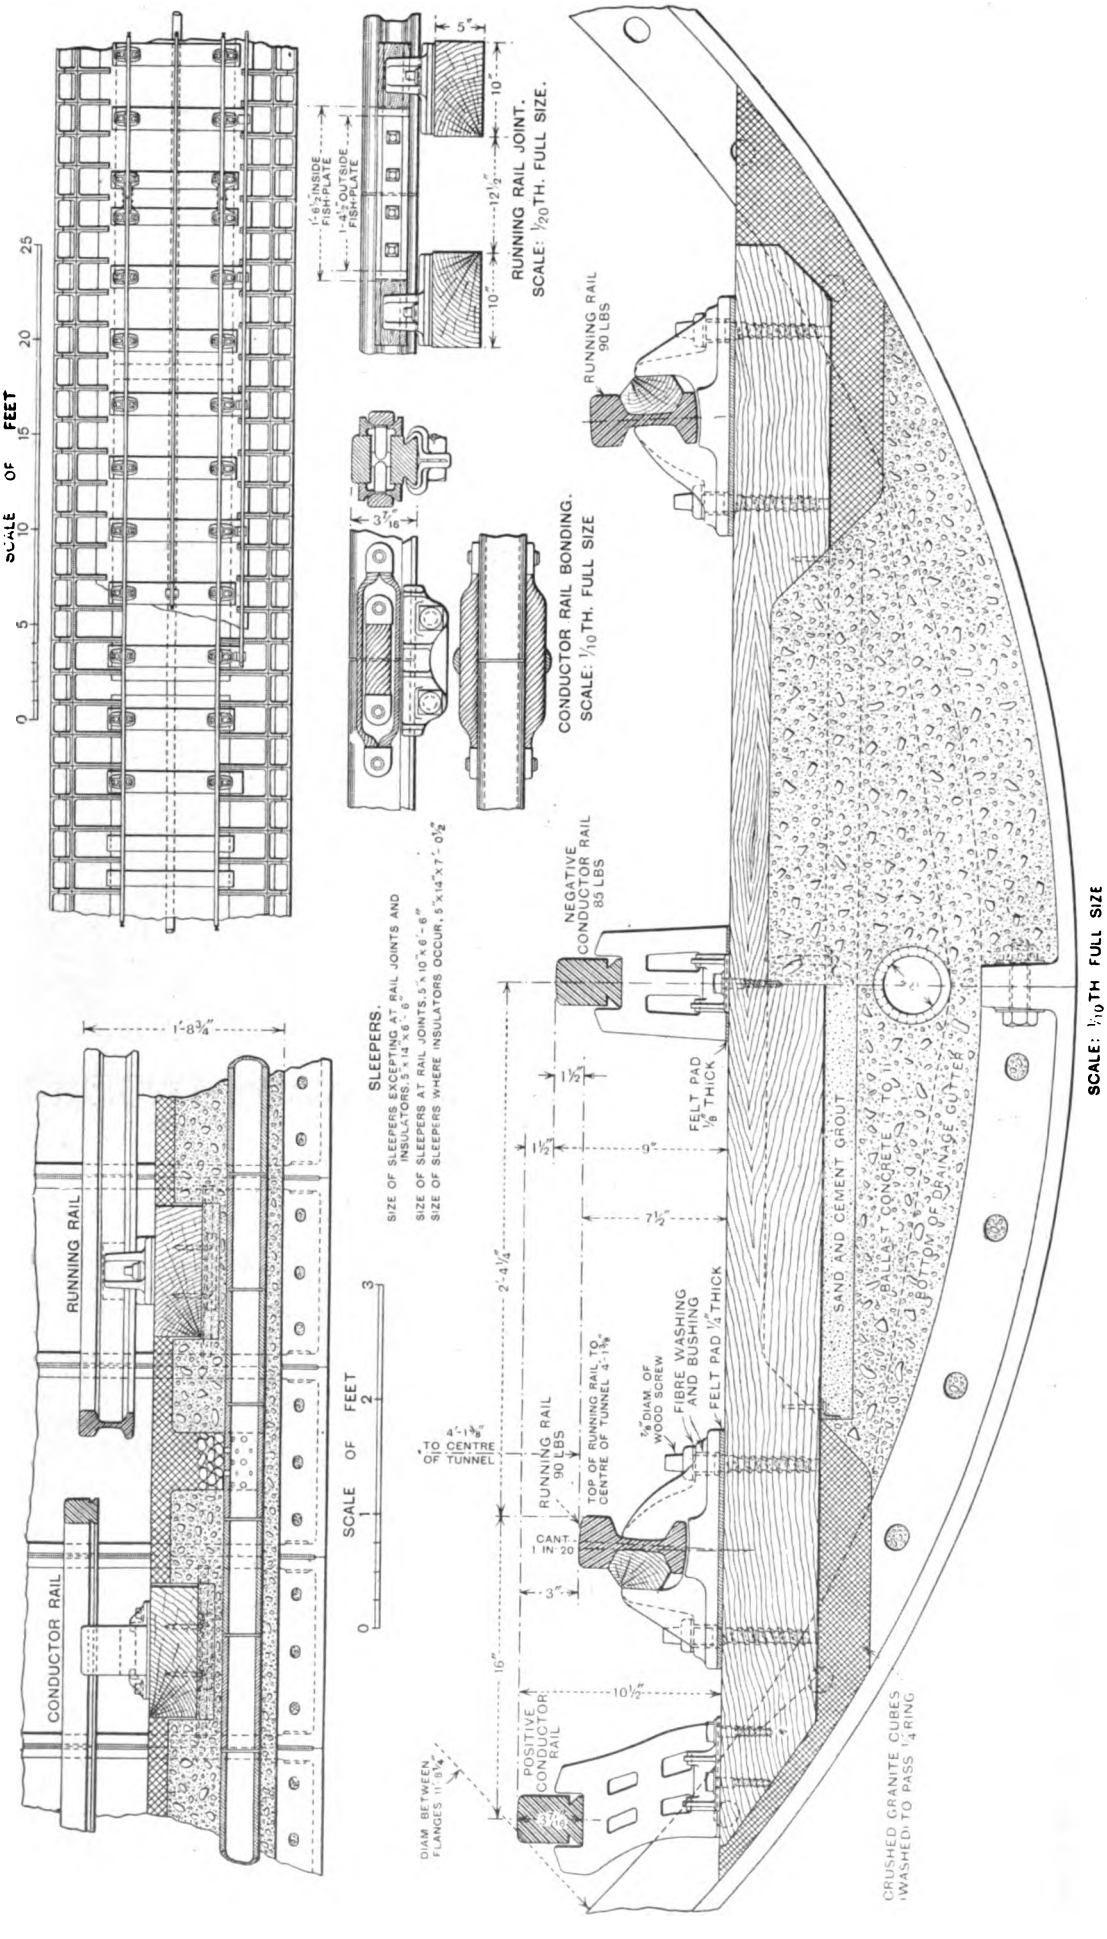


FIG. 2.—SECTIONS AND DETAILS OF ARRANGEMENT OF TRACK AND CONDUCTOR RAILS, BAKER STREET AND WATERLOO RAILWAY.

Digitized by Google

those on the District Railway, were made about the end of the constructional period, and were therefore subject, but in a much lesser degree, to the possibility of the same general disturbances. The conditions of weather and temperature were, however, practically eliminated in these deep level tunnels. The following measurements were made on the "up-road," between the cable passageway beneath the London Road sub-station and the far end of Baker Street Station platform, a distance of 3·47 miles :—

Between positive (outer) and negative ...	570 volts.
,, ,, and earth	510 ,,
,, negative and earth...	60 ,,
Leakage, positive to negative	0·5 amperes.
,, current per mile of single track ..	0·144 ,,
,, positive earthed	5·0 ,,
,, negative earthed	0·57 ,,

Current was on for 2·5 hours on the preceding afternoon, and for 3 hours continuously and immediately preceding the above measurements, and the insulators were supposed to have been cleaned before the observations.

The polarity of the conductor rails was reversed immediately after the preceding readings and the pressure applied continuously for 48 hours, all other conditions remaining the same. Readings were taken regularly between the outer rail (now negative polarity) and earth, the results being shown on Fig. 3.

At the end of the 48 hours the following readings were taken :

Between positive (centre) and negative ...	570 volts.
,, ,, and earth	455 ,,
,, negative and earth...	115 ,,
Leakage, positive to negative	0·5 amperes.
,, current per mile of single track .	0·144 ,,
,, positive earthed	2·8 ,,
,, negative earthed	0·7 ,,

These results show that the potential between the outer rail and earth was reduced from 510 (positive to earth) to 104 volts (negative to earth) in 24 hours. Some local disturbance then caused a sudden rise to about 118 volts, after which it again slowly but steadily fell to 115 volts at the end of 48 hours. During the first half-hour immediately following the reversal, the leakage current increased steadily from 0·5 to 1·27 amperes, and then gradually became less. It reached the normal value of 0·5 of an ampere on or before the end of the 48 hours.

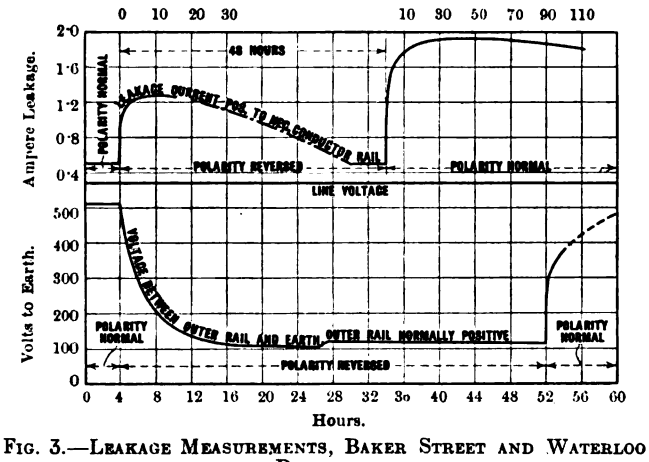

Fig. 3.—Leakage Measurements, Baker Street and Waterloo Railway.

The polarity of the conductor rails was again made normal—immediately after the 48-hour run with polarity reversed—the increase in leakage current and the variation in potential between the outer rail and earth for the first two hours being also shown in Fig. 3. The leakage current rose rapidly immediately following the change from reversed to normal polarity, the maximum value of 1·92 amperes being reached in about 35 minutes.

The conductor rails were alive, normal polarity for running trains a total of 117 hours between the readings on January 4th and the following readings on January 16th, 1906 :—

Between positive (outer) and negative ...	565 volts.
,, ,, and earth...	530 ,,
,, negative and earth	35 ,,
Leakage, positive and negative	0·32 amperes.
,, current per mile single track ...	0·092 ,,
,, positive earthed	5·70 ,,
,, negative earthed	0·35 ,,

The following measurements show the effects of reversing the polarity of the conductor rails, the rails having been alive about 24 hours, normal polarity, for running trains between the tests of January 16th and 19th. The rails were alive continuously for 43·5 hours between the readings of January 19th and 21st with the polarity reversed; that is, outer rail negative—and for 21 hours, normal polarity, between the readings of January 21st and 22nd. Fig. 4 gives full details of these tests, and Fig. 3 the details of similar tests on the same road and under practically the same conditions.

		Jan. 19.	Jan. 21.	Jan. 22.
Between positive and negative...	volts	575	575	575
,, outer rail and earth ...	,,	531	112	530
,, centre rail and earth ...	,,	44	463	45
Leakage, positive to negative ...	amperes	0·29	0·35	0·3
Amperes leakage per mile single track ...		0·084	0·101	0·087
Leakage, outer rail earthed ...	amperes	4·3	—	—
,, centre rail earthed ...	,,	0·3	—	—
Approximate distance	miles	3·47	3·47	3·47

Some tests with similar results made on the "down" road are also recorded in the Paper.

The results are corroborated by many other measurements made during the years of 1903–1907, all of which plainly and unmistakably show the existence of the phenomena substantially as illustrated in Figs. 3 and 4. There has been considerable study and investigation as to what actually takes place at the time of reversal, the general consensus of opinion being that it is an ordinary case of electrolytic action combined with ordinary insulation resistance conductivity. These results seem to depend upon one form of phenomenon which has long been known in connection with static charges, namely, that a negatively charged conductor leaks away its charge with much greater facility than does a positive; or virtually that under the same conditions a positively electrified conductor is better insulated. A negatively electrified conductor appears to be continuously discharging negative ions, which have the effect of conferring conductivity on the surrounding gas and of causing deposition of moisture from air more or less saturated. It is perfectly conceivable, therefore, that this negative discharge should favour the depositing of moisture between the surfaces of insulators progressively in such a manner that a slight conductivity might be conferred upon the insulator surfaces, and that this effect might be expected to be absent with the positive side of the system. The film of liquid existing between the electrodes on a glass surface will gradually move from the positive to the negative electrode, and the negative insulators may therefore lose their insulating properties by having moisture drawn upon

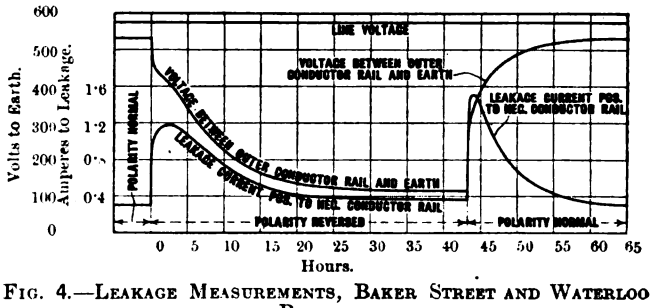

Fig. 4.—Leakage Measurements, Baker Street and Waterloo Railway.

them, an action which does not take place on the positive side. The reducing or chemical action of the ions liberated at the positive rail insulator may result in the formation of compounds which lower the resistance of the negative insulator, while the oxidation which takes place at the positive insulator may improve the insulation.

Conclusions.—These results, whatever the immediate cause or the reason, have clearly demonstrated certain facts which are probably applicable to all similar installations, and may be briefly summarised as follows :—(1) That the difference of potential between the positive conductor and earth is always normally considerably greater than the potential existing between the negative conductor and earth. (2) That this difference between the positive and negative insulation becomes more marked the longer the conductors are subjected continuously to a difference of potential in the same direction. (3) That a reversal of the polarity is always instantly accompanied by a considerable increase in the normal leakage current between the positive and negative conductor. (4) The above phenomena can be repeated indefinitely and are independent of the length of time that the pressure has been previously applied to the conductors in either direction. (5) That the insulation of the negative conductor to earth cannot be proportionately maintained.

THE ELECTRIFICATION OF THE VICTORIAN RAILWAYS.

THE question of the electrification of the suburban railways of Melbourne has been under consideration for over a year, and there now seems to be every probability of the commencement of the work in the near future. It will be remembered that Mr. Charles H. Merz was appointed consulting engineer to the undertaking about a year ago, and was ordered to prepare a full report for the guidance of the Victorian Government, together with recommendations as to the most serviceable system, and the probable financial results. As mentioned in a previous note on the subject on page 759 of ELECTRICAL ENGINEERING, Vol. III., the original proposal was to convert at first only the St. Kilda and Port Melbourne lines, 3½ and 2¼ miles of double track respectively, but according to the latest information, the first instalment will include a much greater length of track.

In a published interview with Mr. J. A. Boyd, a member of the Victorian Government, who has just completed a tour of inspection of the British electric railways, the *Railway Times* states that Mr. Merz's report is now complete and will shortly be presented to the Victorian Railway Commissioners, who will in turn lay the matter before the Government of that Colony. It is believed that Mr. Merz will include in his report, besides the St. Kilda and Port Melbourne lines, the lines of Essendon and Brighton as the first instalment. The length of the Essendon line is 5 miles, while the Brighton line is 9 miles long, so that, including the St. Kilda and Port Melbourne lines, the total route length to be electrified would be 19¾ miles, or about 40 miles of track. It is expected that the adoption of the third-rail continuous-current system will be recommended in the report, similar to that of the Tyneside lines of the North-Eastern Railway and the Liverpool-Southport line of the Lancashire and Yorkshire Railway. The report contains full specifications to enable the Commissioners to call for tenders immediately the Government's sanction has been obtained.

The Melbourne suburban railways comprise altogether 149 miles, practically the whole of which is double track. Most of the lines run eastward of the city, which is the principal residential area, and it is here that the congestion of traffic, which has compelled the authorities to consider electrification or duplication of the track, has been most felt. The power station will probably be located at Laverton, a point considerably to the west of the city, where some large coal-beds lie undeveloped.

Should the present scheme be accepted by the Government, the results should provide useful data for further extensions. The mileage of the suburban railways, as we have already seen, is 149, the track mileage amounting to 263 miles, while there are 148 suburban stations. The total population served is 531,000. The latest available figures relating to the Melbourne suburban railways are those for the year ended June 30th, 1907. These show that 2,992,283 train miles and 24,455.631 car miles were run during the year. There were 64,162,344 passenger journeys, the passenger mileage being 305,071,565, and the average distance travelled by each passenger (single trip) 4·76 miles. The average seating capacity per car was 52, the average seating capacity per train mile 420, and the average number of passengers per car mile, 12·47. The surburban revenue (exclusive of parcels, mails, &c.) was £645,448, the revenue per train mile being 51·77d., per car mile, 6·33d., per passenger mile, 0·50d., per passenger journey, 2·41d., per mile of railway, £4,332, and per mile of track, £2,454.

The Korn System of Telephotography in Denmark.—Our Danish contemporary, *Ingeniören*, contains a report of a lecture by Prof. Korn, of Munich, in connection with the first apparatus being installed in Denmark for the daily paper, *Politiken*. The apparatus described was similar to the installation recently experimented with at the offices of the *Daily Mirror* in London (see ELECTRICAL ENGINEERING, Vol. II., page 766), and it is unnecessary to repeat the details of the arrangement for employing the variations in the resistance of selenium under the influence of light to attain the desired result. After the lecture Prof. Korn showed the apparatus that is to be used by the daily paper, *Politiken*, in Copenhagen, and *Dagens Nyheter*, in Stockholm. A photo was telegraphed from the one apparatus to the other, and after that an attempt was made to receive a photo sent from Berlin. This was, however, not successful, because of some fault on the circuit by means of which the current from Berlin was considerably weakened. Prof. Korn, however, claims to have sent photos successfully over much greater distances, but it appears that mishaps like this will always be liable to take place as long as the circuits used are not especially arranged for telephotography.

TRAMWAY ACCIDENT AT LIVERPOOL.

AN unfortunate tramway accident, resulting in slight injury to some of the passengers, occurred in Liverpool on Friday last. The scene of the accident was the junction of Lambeth Road and Commercial Road in the Sandhills district, at the north end of the city near the docks. Shortly before nine in the morning, a workmen's car with thirty passengers, which was descending the steep gradient of about one in fourteen of Lambeth Road, suddenly left the rails, according to the local papers, and collided with a lorry heavily laden with paper. According to the official account of the accident, however, the car did not leave the rails before colliding with the lorry.

The official report states:—"Car 443 Breckfield Road and North Docks, in charge of Driver Richard Walsh and Conductor John Doyle, was proceeding down Lambeth Road at about five minutes to nine. Everything went well until it reached the bottom of Lambeth Road, when for some unexplained cause the driver failed to stop the car at the junction of Lambeth Road and Commercial Road, and allowed it to travel across the road, when it collided with a wagon loaded with paper materials. The car at this point tilted over from the force of the collision on to the wagon. As a result of this some of the passengers were thrown from their seats, and some of them were injured by the falling of broken glass. Six passengers who were suffering from what turned out to be comparatively slight injuries were taken to the Stanley and Northern Hospitals, where they received prompt attention, and were then able to proceed to their homes. The only person whose injuries were of a serious character was the driver, who still remains an inmate of the Stanley Hospital. It may be mentioned that the brakes, both electric and hand, were tested immediately after the accident, and were found to be in perfect order, together with the whole of the car equipment."

Prior to the commencement of the business of the meeting of the Tramways Committee on Friday, Sir Charles Petrie, who presided, referred to the accident, and said that the driver was a man who had been in the tramways' employ for a considerable number of years, and bore an excellent character. So far they did not know the cause of the mishap, but an inquiry would be held.

Mr. C. W. Mallins, the General Manager of the tramways, informs us that the first accounts of the accident were grossly exaggerated, and has sent us a statement, made by the driver, as to how the accident occurred. He commenced to descend Lambeth Road at a low rate of speed on the electric brake, and brought the car to the bottom of the hill in perfect safety, where it was necessary to put on the hand-brake to hold the car stationary at the compulsory stopping station. In doing so he inadvertently failed to put the clutch into the proper position to engage in the teeth of the ratchet wheel at the base of the brake staff, with the result that the hand-brake flew off and the staff struck him a heavy blow on the elbow, disabling his arm for the moment, and thus allowing the car to go without the brake for a distance of 18 to 20 yards, where it collided with a wagon, thereby causing the accident. In addition, he says the brakes and other equipment were in perfect condition, and the car did not leave the metals. Had the waggon not come in the road he would have been able to put the brake on immediately afterwards, and have brought the car to rest, thus avoiding the accident. The force of the collision with the waggon disturbed the equilibrium of the car, as it was on the curve at the time, causing it to cant on to the waggon. This statement is corroborated to a great extent by passengers who were travelling in the car at the time.

German Regulations for Accumulator Factories.—According to *Engineering*, some new regulations concerning the hygienic arrangements in lead accumulator works came into force in Germany on July 1st replacing the regulations of 1898. Floors of wood, asphalte, or linoleum are forbidden in rooms in which lead-dust or vapours may form; the walls and ceilings should be painted in oil, or be whitewashed at least once a year. All dust and vapour must be sucked up at the point of origin; this refers to lead-fusing, sawing and cutting, to the preparation of lead-dust, and to sifting and mixing the compounds. All soldering has also to be performed under suitable ventilation-hoods. The zinc and sulphuric acid for generating the hydrogen, used for soldering, must be technically pure. The employer must provide his men with suitable clothes for carrying on the dangerous work; there must be tooth and nail-brushes in the lavatories, and the men must take a warm bath once every week. Female labourers and boys must not be employed at all in the lead department. The rooms for meals must be kept entirely apart from the others, and the men are not permitted to enter those rooms before changing their garments. The use of alcohol and tobacco is forbidden. Nobody may be employed in the lead department who is not certified as fit by the physician, who has to examine all the employees at least once every month. The employer and the physician have to keep records of the men's work and state of health. Dangerous work may be performed either on a shift of eight hours, with a break of at least one hour and a half, or in a shift of six hours.

ELECTRIC LIGHT AND POWER IN THE WEST-END PREMISES OF MESSRS. DEBENHAM AND FREEBODY

THE electric lighting and power arrangements in the fine new premises of this well-known drapery establishment in Wigmore Street afford an excellent example of the perfect control which may be obtained over the lighting and power supply of a large business concern, both as regards efficiency and economy, by the application of electricity for these purposes. The fine block of buildings, most of which is comparatively new, occupies a ground area of some 32,000 sq. ft., and is divided into two halves: the retail and the wholesale departments respectively. This block stands entirely by itself, but is connected by an underground passage to a small block of buildings used as cloakrooms and stables, on the opposite side of a narrow road at the back of the main building. The incoming service cables, of which there are two, are both brought in to the main switchboard room situated in the basement under the stables. Supply is taken from the mains of the Marylebone Borough Council, and is continuous-current three-wire, with 480 volts across the outers. The charges, both for lighting and power are on the maximum demand system; and in order to take advantage of the fact that the maximum demand of the building as a whole is less than the sum of the maximum demands of the various portions, it was decided to take in the service cable at one point only, whereas from other points of view it would have been more satisfactory to have supplied the building from several different services led in at convenient points. There are two service cables, however. These are concentric, each consisting of two outers and a neutral. They are taken from different sections of the distributing network, and are connected respectively to the two sides of a two-way change-over switch, after first passing through the Marylebone Council's fuses, maximum demand meters, and energy meters. There are three energy meters on either side of the three-wire system, these being for the basement lighting, upper-floor lighting, and power respectively. The basement lighting supply is on a flat rate, but the other two supplies are on the maximum demand system. The three-wire system is divided at the intake into positive and negative halves, so that all the above meters, including the power meters, are connected between one outer and a neutral. The two halves of the system are kept entirely separate, the lighting and power being divided between them, with the exception of a few 480-volt motors, which are connected across the outers of the power cables. There are in this switch room six energy meters and four maximum demand meters belonging to the Marylebone Council; another set of sixteen maximum demand indicators, eight on each side of the system, register the maximum demands of the different departments. These latter meters are read every night and re-set every month, as the lighting and power costs are charged up separately to each department, the manager of each department keeping careful accounts of all expenses in his department. The necessity for thus metering the consumption of each department separately rendered the wiring of the building particularly difficult, and as will be explained later, nearly every circuit is provided with a meter.

The rates charged by the Marylebone Borough Council are those in force all over Marylebone, namely, a flat rate of 2d. per unit for the basement; an upper-floor lighting rate of 8d. and 1d.; and a power rate of 2d. and 1d. For the winter months, an amount equivalent to 200 hours per quarter at the maximum demand is charged at the high rate, and in the summer an amount equivalent to 50 hours at the maximum demand. From the main switch room the cables run to a large distributing board in an adjacent room, which consists of a positive and a negative half. There are sixteen panels in this board, one of which is diagramatically illustrated in Fig. 1. Each panel contains the apparatus needed for six circuits. Each circuit is provided with a double-pole switch, fuse, electrolytic meter, ammeter, and in the case of the arc-lamp circuits, of which there are sixty, a clock. Although there is provision on the

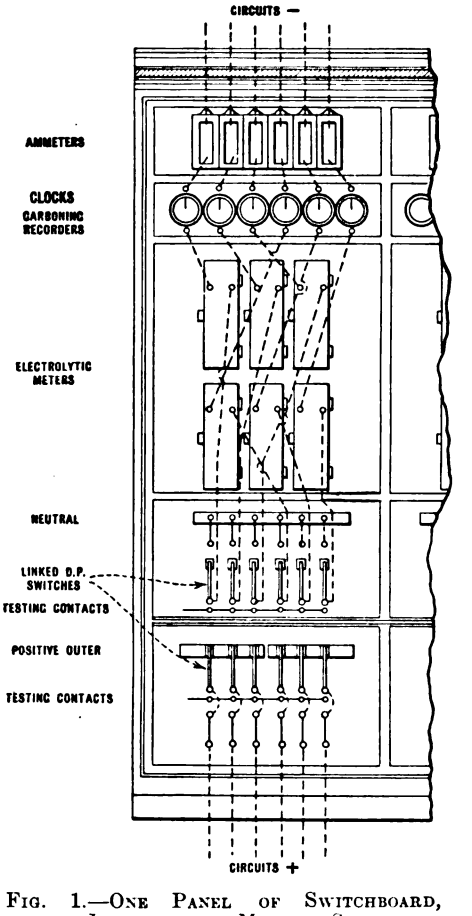

FIG. 1.—ONE PANEL OF SWITCHBOARD, SHOWING INSTRUMENTS, METERS, SWITCHES, AND CLOCKS FOR SIX ARC LAMP CIRCUITS.

board for sixty arc lamp circuits, or 300 lamps, only 44 of these circuits have been installed at present.

The use of the clocks or "carboning recorders," in the arc-lamp circuits is as follows:—The arcs are of the open inverted pattern, and are connected five in series, each group of five constituting a circuit, and having a switch, fuse, meter, ammeter, and clock on the distributing board, as described above. There are in all 220 lamps, of which 200 are 8-ampere, and 20 are 5-ampere arcs. The former burn about nine hours and the latter seven hours before needing fresh carbons. After any particular group of lamps has been trimmed, the clock corresponding to the group is set to twelve o'clock; when the lamps are switched on, a sole-

Digitized by Google

noid and detent device releases the clock mechanism, and the clock thus registers the number of hours the group of lamps has been burning. The switchboard attendant can thus, by glancing at the clocks, see at once when any group of lamps requires trimming, and can also make certain that all lamps have sufficient carbon to last through the day, before switching them on, except on foggy days, when they may be alight all day.

The other pieces of apparatus in the room include four large ammeters on the two lighting and power circuits, and two recording voltmeters, one on the positive and one on the negative side of the system.

There is also an insulation resistance recording instrument in connection with the insulation-testing system which is worthy of a full explanation. This system is patented by Mr. A. D. Stevenson, the consulting engineer to Messrs. Debenham & Freebody. It consists of the recording instrument mentioned above, which is practically a recording voltmeter, the resistance of which is about 14,000 ohms, a three ampere-hour, 200-volt E.P.S. battery with charging board, and a number of contacts which put all the lighting and power circuits in parallel on to the testing set. These contacts, which are indicated in Fig. 1 (p. 319), are so arranged under the double-pole circuit switches, that when the switches are opened the circuits are totally isolated from the supply mains, but are put on to the testing set. A continuous test is thus being made of all of the circuits which are not at the time connected to the mains. A fault in a basement circuit will thus be indicated at night when that circuit is switched off, and in the case of the lighter rooms, the record of a fault would, of course, continue in the daytime. If a fault is indicated, the switches are one by one lifted off the testing contacts until the voltmeter indicates that the fault has disappeared. That particular circuit is then inspected, and the fault localised and repaired. The battery and the charging board are situated in the main switch room. The battery is charged for one hour every week, but it would keep the system working continuously for three weeks on one charge.

A novelty in the main switch room is a lamp-pairing board for pairing the 120-volt Osram and Tantalum lamps which are used in series; as there are 370 Osram and 170 Tantalum lamps in use in the building, all connected two in series, this little board is found very useful. It carries two lamp-holders connected in series, a voltmeter, and a two-way switch for putting the voltmeter across either of the two lamps under test.

As previously mentioned, the main switch room is situated in the basement of the separate building used as stables, &c. By putting the main two-way switch in the neutral position, the main building is entirely cut off from the supply. This is done every evening by the switch-board attendant. The lighting of the other building, in which live certain members of the staff, and in which are also situated the rooms of the fire brigade, is supplied quite separately from another service point with the ordinary complement of meters, fuses, &c.

We now come to the lighting arrangements proper. Wherever practicable, the system of indirect illumination by inverted arcs has been followed. The open spaces and the unusual freedom from obstruction due to partitions and columns, gave opportunity for the use of large units of light, thereby conducing to a considerable economy in current consumption; while at the same time the requirements of even diffusion of light and intrinsic brilliancy at every point are met by the adoption of the indirect as opposed to the direct method of illumination. The type of lamp adopted is that of the Union Electric Co.'s open inverted arc, and these are fitted with inverted reflectors for the purpose of throwing the light up to the ceiling, where this is sufficiently near the correct hanging level of the lamp to afford a good even illumination. The reflector used is a 19½ in. diameter enamelled cone.

In cases where the ceiling is not sufficiently near the crater of the arc to give a sufficiently strong illumination, over-reflectors, constructed with a surface of vitrified white enamel, and measuring 35½ in. in diameter, are fitted. These are placed approximately 12 in above the arc, and a small under-reflector measuring 12 ins. diameter, is placed immediately below the arc, so as to catch any rays which may fall at an angle greater than about five degrees to the horizontal.

As the under reflectors are not large enough to comply with the insurance companies' specified minimum diameter of 3 ft. 6 ins. for open unprotected arcs, it was necessary to fit all the lamps with glass cylinders. These cylinders do not improve the distribution of the light, and moreover, they absorb a certain amount of the light, which is sometimes said to be as much as 15 to 20 per cent.

The light from these arcs is said to be excellent for matching colours. In the days of the carbon glow lamp, material was taken to a special room for matching in the evening, which was lit by a "Jandus" enclosed arc lamp, with a special coloured glass globe. The light from the inverted arc lamps is found, however, to be quite suitable for this purpose.

There is no special lighting for the windows, which are deep and glazed in (as is seen on the left hand side of Fig. 2). The inverted arcs near the windows are moveable to the extent of one or two feet away from, or towards, the window front, as they are hung from rails. The whole of the illumination of the windows is thus derived from the general illumination of the showrooms. The windows are only very lightly draped above, and this arrangement is found to answer very well. There are a few arcs on the exterior of the building, but these are too high to help much in the illumination of the windows.

One great advantage of the uniform diffused illumination is that the arrangement of the showrooms can be altered, and show cases and counters placed in different positions, without the necessity of altering the lighting arrangements, as would most certainly be necessary if a large number of small units were employed. Besides the inverted arcs, a few pairs of 50-c.p. Osram lamps are hung in each room, but these are only used when the rooms are closed to customers, and a small amount of light is required for cleaning or other purposes.

There are no switches in the rooms for the arc-lamps; if they are needed, the switchboard attendant is telephoned to. The switchboard attendant has all the arc circuits under his control, and he is thus enabled, by switching off wherever possible, to keep down the maximum demand. This is especially important at the end of September, when the lamps are just beginning to be used.

As the lamps are arranged five in series, and as there was often need for a fewer number of lamps in one showroom, much difficulty was experienced in grouping the lamps so that the departments were all kept separate. Lamps which might be required for late working, had also to be kept on separate circuits, to avoid burning lamps unnecessarily. The restaurant and the reception rooms are lit with groups of Osram lamps in fours, shaded with frosted glass diffusing globes. The metal fittings for these lamps, and also the copper covers and reflectors for the arcs, were supplied by the Birmingham Guild of Handicrafts. In the offices and smaller rooms, tantalum lamps, arranged two in series, are used.

The dressing and fitting-on rooms, of which there are several, are each fitted with a group of four 50-c.p. Osram lamps, without frosted globes. The mirrors

Digitized by Google

are fitted with "Linolite" lamps at top and bottom. There is also a wall plug for a portable lamp, and another pattern of plug on the heating circuit for a radiator. Flush-type switches are used. In a few cases there was occasion to have two arc lamps only, and so two 120-volt enclosed arc lamps were connected to the 240-volt circuit in series. In the basement and particularly in the old portion of the building, there is a large number of carbon filament lamps. In all there are 230 arc lamps, 700 carbon filament lamps, 370 Osram lamps, and 170 tantalum lamps.

In an establishment such as that under consideration, there are not many opportunities for the application of electric power. In the present case the total horse-power installed aggregates only 110 h.p., and is divided up among 50 motors. Of these, two are 5-h.p. motors driving blowers for supplying air to the basement rooms. The air is taken in at two points at about the level of the first floor, and blown through dust filters and moistening screens. It is then supplied with a quantity of ozone from "Ozonair" generators, and passed through brick ducts under the floor. It was necessary to pass the ducts under the floor, as otherwise the isolation provided by the fireproof partitions and sliding doors would have been rendered useless. There are also two extracting shafts, measuring 3 ft. by 5 ft. internally, and extending from the basement to the roof. At the top of each there is a 3-h.p. motor driving a 48-inch extractor fan. All the rooms are connected with the shafts, the gratings being provided with adjustable louvres. The two 10-plate ozone generators which supply ozone to the incoming air have their own transformers. There are 15 other generators distributed amongst the various workrooms; a transformer in each workroom operating a group of generators. The current for the transformers is obtained from a special circuit supplied by a 1-h.p. converter running off the 240-volt power circuit, and generating at 160 volts 50 cycle alternating current. The transformers transform up to from 3,500 to 5,000 volts, and the current is conveyed to the various ozone generators hung from the ceilings of the workrooms, by rubber-covered wires drawn through tubes made of a rubber-fibre compound. The generators in these rooms have no fan attached, the ventilation of the room being considered sufficient to cause the necessary circulation of air. The operating pressure of the generators can be varied between 3,500 and 5,000 volts by switches on the primary sides of the transformers. This ozone generating installation was not in the original scheme designed by Mr. Stevenson.

Another application of electric power is the parcels conveyor. The parcels come down from the various departments in spiral chutes, and alight on travelling belts, which in turn convey them to a rotating table which passes them before men who pick out the particular parcels they have to deal with as they pass them on the table. A number of small motors are employed to run this conveying plant.

Several sewing machines in the workrooms are electrically driven. The operation of switching on is performed by pressing the treadle, which starts the motor and then puts on the clutch. There are 16 electrically-heated Prometheus flat-irons in the workrooms. To prevent these being left on after working hours, each is provided with a lamp which is alight when the iron is switched on. It was found, however, that these lamps were used for illuminating purposes by cleaners, &c., and high voltage lamps were therefore substituted for the normal voltage lamps. These only give a slight glow. Screw holders are used in order that the normal lamps cannot be put in these indicating lampholders. Electrically-heated glue-pots, with a similar arrangement of indicating lamp, are to be found in the packing room. The heating of the building is done by steam, but there are a few electric radiators in use.

The wiring is entirely in screwed steel conduit. In the showrooms and other retail departments it is hidden, but in the basement and in the wholesale departments it is on the surface. The contractors for the whole of the electrical work, with the exception of the Ozonair installations and the electric lifts, were Messrs. Thompson, Ritchie & Co., Ltd., who supplied the switchboards and fittings. The switchboards were constructed to the design of Mr. A. D. Stevenson, the consulting engineer, who also superintended the carrying out of the whole of the work, including the heating arrangements and the ventilating arrangements, and who courteously showed our representative over the establishment.

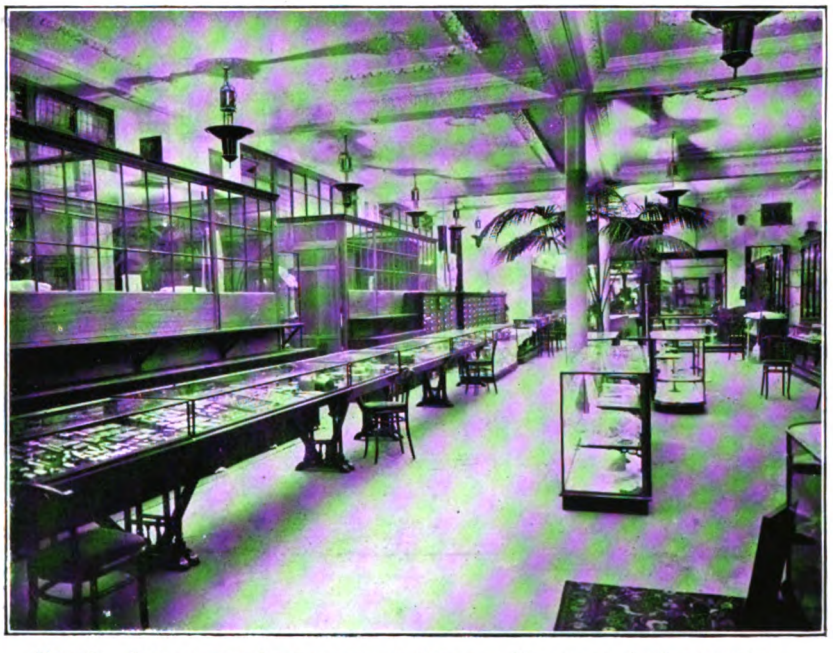

Fig. 2.—One of the Showrooms at Messrs. Debenham & Freebody's. The Photograph was taken by the Light of the Inverted Arcs.

The premises are equipped throughout with a service of uniform and accurate timepieces by means of the well-known "Synchronome" system. The electrically operated pendulum clock is of the latest type with the detached gravity escapement, the joint invention of Sir H. H. S. Cunynghame, and Mr. F. Hope-Jones. This master-clock operates 66 dials, arranged in the various rooms all over the building. These dials are all connected in series. The master-clock sends a current impulse every half-minute. The operating current is very small, and is derived from a primary battery.

The main building is provided with a service of electric lifts, comprising four passenger lifts of the "Otis" standard drum type, three of which have a lifting capacity of 1,600 lbs. at a rate of 250 feet per minute, and the fourth, a capacity of 2,500 lbs. at a rate of 250 feet per minute. These lifts are operated by two-speed switches in the cars. Some of the lifts are provided with compartments below the passenger compartment for the reception of parcels. There are also three service lifts of the standard "Otis" pattern, with push-button control.

THE UTILISATION OF ELECTRIC POWER IN SALT MINES

By H. R. Speyer

SITUATED in the midst of the Harz Mountains is a group of salt mines owned by the Nordhauser Kali Company and the Immenrode and Ludwigshall Carnallit Companies. The three concerns are distinct from one another, and each is controlled by its own board of directors. A joint board was, however, formed for the purpose of discussing the advisability of erecting a common generating station for supplying the pits with electrical power, and ultimately a site was chosen for this purpose almost midway between the Nordhauser and Immenrode mines, and at the mouth of the Ludwigshall pit adjoining the chemical factory in the position shown in Fig. 1.

Before entering upon a description of the power house and the electrical equipment at the mines, a few notes may be given on the processes the raw material has to pass through before the final product is obtained. The raw material is brought to the surface by electrical main winding engines, and is transmitted to the factory, a distance of some three to four miles, over an electrically driven aerial steel ropeway, and is shot from the incoming trucks automatically by electrical

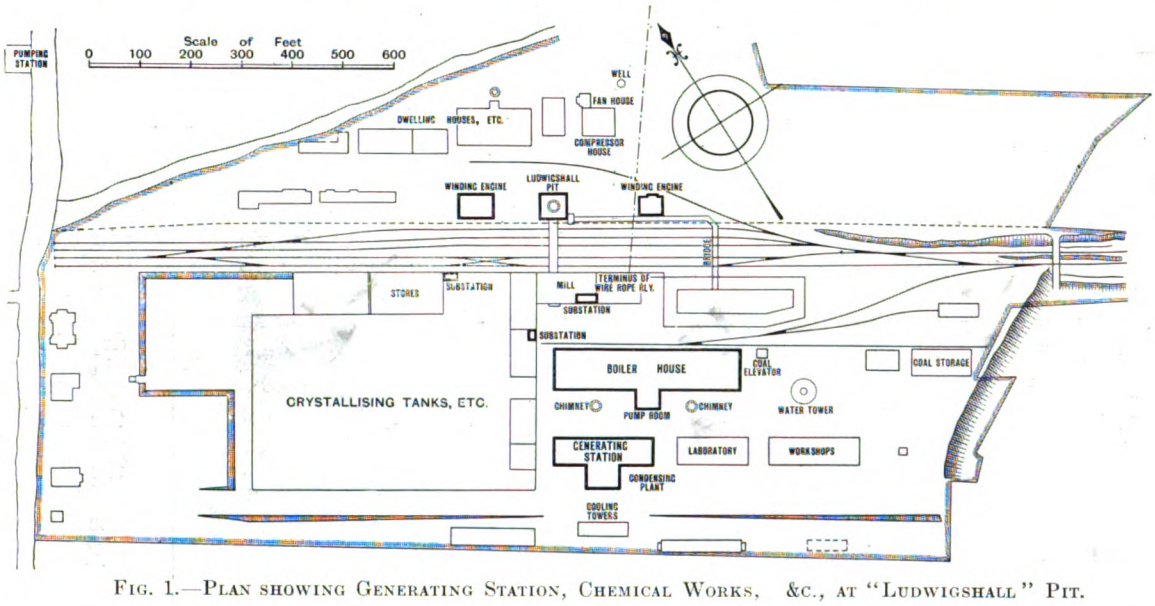

FIG. 1.—PLAN SHOWING GENERATING STATION, CHEMICAL WORKS, &C., AT "LUDWIGSHALL" PIT.

FIG. 2.—MAIN SWITCHBOARD IN GENERATING STATION.

Digitized by Google

tippers into the mills. Issuing from these in a pulverised form, it is taken by conveyors to the top of the building, where it is dropped into the live steam-heated boilers containing a solution of calcium chloride. Here the original salt, consisting of carnallite and sodium chloride, undergoes the first chemical change. The carnallite dissolves, and the sodium chloride remains in its solid state. The liquid is drained off and pumped into large open tanks, where the potassium chloride crystallises out. This is afterwards taken to revolving drying pans fitted with spiral blades which discharge it in its dry state into hoppers, for transmission to the stores. The remaining filtrate, after the crystallisation of the potassium chloride has taken place, is pumped through to the vacuum pans, when the process of crysallisation is furthered, and the magnesium chloride brought down. This is taken to the drying pans, and by another set of hoppers and elevators carried thence to the stores. As already mentioned, the sodium chloride and magnesium sulphate pass through the dissolving boilers in a solid state and are afterwards taken over to the stirring pans

Fig. 3.—High-tension Switchgear in Central Station.

and mixed with water, when the sodium chloride dissolves out and the magnesium sulphate comes down in the form of a heavy precipitate, giving a salt known as kyserite. The mixing of this salt with the original potassium chloride in solution produces potassium sulphate. We have thus four commercial salts, potassium chloride, magnesium chloride, potassium sulphate, and magnesium sulphate. The percentages in which they are produced are approximately 80 to 90, 50, and 48 to 70, and 50 per cent. respectively.

As can be seen from the above description, the requirements for producing the commercial salts from the raw material are such that, with the exception of the live steam heating for the dissolving boilers, electricity can exclusively be used. In the first place, the boring operations are carried out electrically; the pit gear, including the underground haulage and winding engines, is driven by electric motors; the transmitting aërial ropeway, the tippers, the mills, the hoppers, elevators, pumps, mixing and storing gear, drying plant, and cranes for loading are in each case driven electrically.

Generating Station.—The power station, when completed, will contain five steam-driven generating sets having an aggregate horse-power of 3,500. At present there are erected and at work on a day and night load four horizontal tandem compound double-crank engines directly coupled to three-phase star-connected high-tension alternators. The two larger engines were constructed by the Hannover'sche Maschinenbau, and each is of 750 h.p. They are fitted with Lentz's patent poppet-valve gear. The two smaller units are each of 350 h.p., and are fitted with ordinary governors. The two larger generators have each a normal output of 550 k.v.a. at 5,250 volts 50 cycles when running at 107 r.p.m. The two smaller generators are designed for an output of 250 kw. at the same voltage when running at 83·3 r.p.m.

The output of these machines, as is usual in such a station, is controlled from a low-tension control board, while all the high-tension is in a separate enclosed chamber. Fig. 2 is a general view of the board, and Fig. 3 shows the high-tension gear. The board consists of 16 sections, comprising five generator, five feeder, two motor-generator, and four spare panels. The high-tension oil switches, potential and energy transformers, and the station main bus-bars are mounted directly behind the switchboard. The method of control from the low-tension switchboard, including the paralleling of the generators, is by relays actuated by press-buttons mounted on the front of the board. The high-tension switches of the generator cables and of the outgoing feeding cables are all actuated by solenoid coils energised from the low-voltage continuous-current circuit (110 volts) and controlled from the low-tension board. In order to enable the switchboard attendant to see at a glance which cables are in use, each panel is provided with two indicating lamps (red and green), one of which is always alight according to the position of the switch. Alarm bells are also provided to call attention to the opening of the circuit-breakers.

The continuous-current switchboard is below the main switchboard (Fig. 2). It controls the lighting circuits, the continuous-current side of the motor-generators, the booster set, and also the exciter circuits. The motor-generators are driven by high-tension three-phase

Digitized by Google

asynchronous 60 h.p. motors. Two transformers of 75 and 30 kw. respectively, transforming from 5,000 volts to 110 volts, are provided for supplying various auxiliary motors up to 35 h.p., and in case of emergency for lighting.

The station was planned and erected in a very short time, and the plant has been running without interruption since last July. The running cost per unit with the load factor of about 20 per cent. has averaged 0·46d., and the standing charges, including interest and depreciation, with a diversity factor of 1, work out approximately 0·8d., making a total of 1·2d. per unit. It is hoped that when the plant at the pits is more complete an appreciable reduction on this figure will be possible The electrical equipment of the station was carried out by the Elektrizitäts-Aktien-Gesellschaft, vorm. Pöge, of Chemnitz.

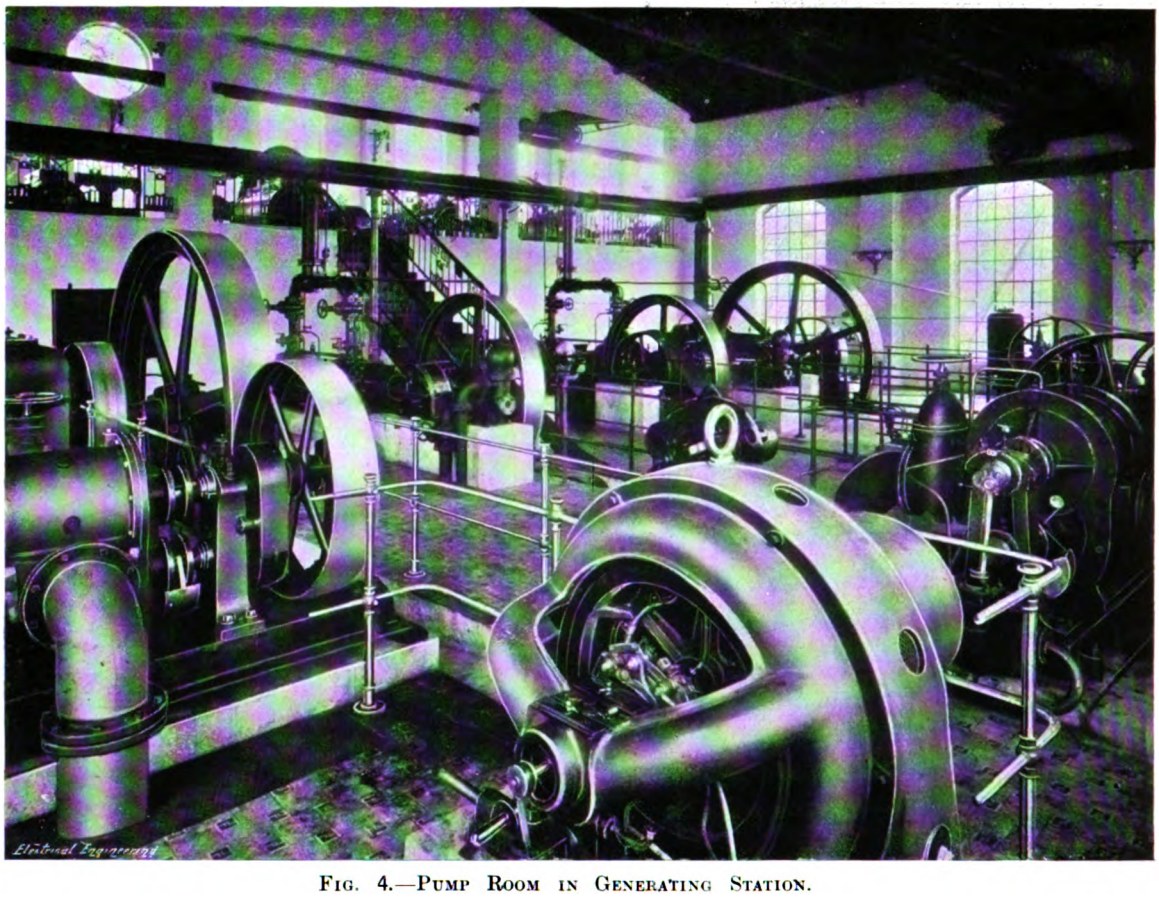

Fig. 4.—Pump Room in Generating Station.

The air pumps of the condensers are not, as is usual on the Continent, driven direct from the connecting rods of the engines, but are grouped together in a separate condenser house adjoining the engine-room. The two main condensers are of the surface type, and are capable of dealing with 8,000 kgs. of steam per hour. They are worked in conjunction with a cooling tower, whose output is 360 cbm. per hour. Each condenser has a cooling surface of 170 square metres. As can be seen from Fig. 4, the driving is through belting. Each motor drives on to an air pump, and back through belting to a cooling-tower pump. The motors are of the 5,000-volt three-phase induction type, each with an output of 45 h.p. when running at 785 r.p.m. The two larger air and cooling-tower feeding pumps seen in Fig. 4, which are driven in a similar way by 80 h.p. induction motors, are those used in connection with the vacuum station. The complete condensing plant was designed and laid down by the Sangerhauser Machine Co.

The boiler-house contains two batteries of boilers, one of eight units for the central station, and one of ten units for supplying live steam to the dissolving tanks. As is generally the case in the salt districts, the natural water contains many ingredients injurious to boiler-plates. For this reason, as well as for the fact that fire-tube boilers have a greater reserve of steam, the Cornish type of boiler was chosen. Each of the eight units put down has a heating surface of 100 square metres, and is worked at a pressure of 10 atm. The fuel used is exclusively "brown" coal. Each boiler is provided with a superheater for raising the temperature of the steam to 280° C. The water from the condensers is passed through an oil separator consisting of baffle-plates and sawdust, and is afterwards used in conjunction with fresh water as feed for the station boilers. An exhaust steam feed heater raises the temperature of the feed-water from 40-50° C. to 75-80° C. The fresh water from the artesian well, before being taken to the boilers, is passed through a "Voran" water-softening plant capable of dealing with 50 cubic metres per hour.

Distributing System and Sub-stations.—In order to minimise the risk of a breakdown, the main high-tension distributing cables are laid in pairs; these are at present, however, worked in parallel, and are controlled from the one switch panel. Arrangements are, however, to be carried out to enable each feeding cable to be dealt with separately. Although this will naturally increase the capital cost per kw. laid down, much increased security against breakdown will be obtained, a point of particular importance when dealing with mining engineering. It may be mentioned here that the station capital cost per kw. laid down, including the boiler, engine, generator, switchboard, and building plant, was approximately £24·6. There are in all five pairs of outgoing main high-tension cables. One pair is laid down between the central station and the Nordhauser Kali Co.'s "Hain" pit, a distance of three to

Digitized by Google

four miles, and a similar pair is laid between the station and the Immenrode pit, a distance of about two miles. The cables are of the Felten & Guilleaume-Lahmeyer paper-insulated three-core type, with a copper cross-section of 0·077 sq. in. per phase. The transmitting pressure is 5,000 volts. The remaining three pair of cables, of 0·025 sq. in. cross-section, are laid between the station and the adjoining chemical factory and the Ludwigshall pit.

Sub-stations are erected at the mouths of the "Hain" and Immenrode pits. These are equipped with high- and low-tension feeding and distributing switch-panels, and with static transformers for giving reduced pressure at 500 and 110 volts—the former for small power works, the latter for lighting circuits. The Felten & Guilleaume-Lahmeyerwerke Co., of Frankfort, have been responsible for the equipment of these sub-stations. In addition to these sub-stations, there are also three in the chemical factory. They supply current at a high and low pressure, and serve as energy-distributing centres for the mills, the drying equipment, and the dissolving plant, which, as can be seen from the plan (Fig. 4), cover a considerable area.

Electrical Equipment at the "Hain" Pit.—The electrical equipment at the "Hain" pit, which is 600 metres in depth, comprises electrical main and auxiliary winding engines. The former is on the well-known Ilgner-Ward Leonard system, and the latter is driven by means of a three-phase motor through a double set of reducing gears. The output of the main engine is approximately 82 tons per hour, and that of the smaller engine is 32 tons per hour.

It is not necessary to enter here upon a further description, as a detailed account of the Ilgner system was given by the writer in an article on the Electrical Equipment of the Mansfeld Copper Mines, published in Electrical Engineering, Vol. III., page 609 (see also page 605 of the same volume for a fuller description of the Lahmeyer form of the system). It may be mentioned, however, that owing to the safety of this system the mining authorities allow a speed, when working with the Ilgner system, of 15 metres per sec., as against the permissible speed of 6 metres per sec. when working with other plant. The speeds here refer only to the case of "live" load. Among the many advantages claimed for the Ilgner system as against three-phase motors driving the winding drum or pulley direct or through gearing is the fact that with the Ilgner-Ward Leonard regulating system the speed of the winding unit at any time is absolutely independent of the load, irrespective as to whether this be positive or negative. This is not the case with three-phase motors controlled by rotor resistances, and accidents through overrunning when lowering have occurred in the writer's experience from this cause which would have been impossible with the regenerative action of the Ilgner system. Again, the absence of gearing does away with the noise which frequently interferes with the driver hearing the signals properly. Another advantage accruing in this particular case to the continuous-current direct-coupled winding motor is that when the underground workings of the mine have increased the main winder must be capable of dealing with the increased output. This in the case of the Ilgner system can be easily catered for by mounting a second continuous-current motor on the other side of the Koepe pulley and by erecting a corresponding motor-generator flywheel set. The output in this case would be doubled, *i.e.*, 3,800kg. With a three-phase system, however, additional mechanical as well as electrical plant would be necessary.

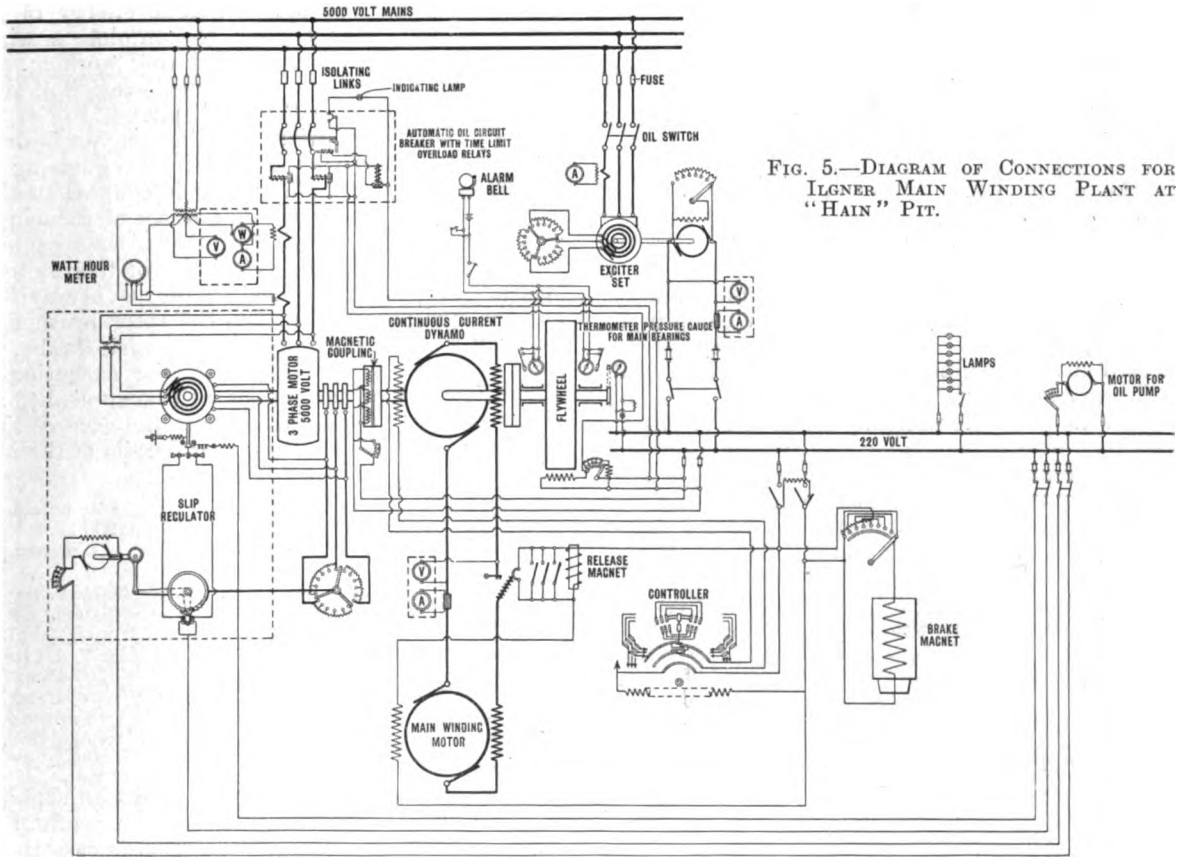

Fig. 5.—Diagram of Connections for Ilgner Main Winding Plant at "Hain" Pit.

It is worth while considering for a moment the comparative efficiency and the capital and running costs of the two systems. These are clearly shown in Table I., and refer to an Ilgner and three-phase plant of the same output, viz., 1,900 kg. per wind. It will be seen from this table that although the actual initial cost of the Ilgner system is more than double that of the three-phase plant, the consumption in energy is less than 25 per cent., and the efficiency nearly 50 per cent. higher.

Table I.

Comparison of Ilgner and Three-phase Systems of Winding.

	Ilgner system.	Three-phase system.
Capital cost—		
Original winding plant for 1900 kg...	100 %	47 %
Extension of capacity to 3800 kg. ...	50 %	100 %

	Per wind, kw. hours.	Per wind, kw. hours.
Energy consumption—		
For raising ore	7·48	10·1
For lowering live load (*a*)	1·31	7·96
,, raising ,, ,, (*b*)	4·90	9·20
Efficiency—		
Transmission to pit	85 %	85 %
Winding motor (average)	80 %	40 %
Ilgner set	75 %	—
Gearing	—	80 %
Overall	50 %	27 %

The particulars of the main winding engine at the "Hain" pit are as follows:—

Output per hour	81·5 tons (later 163 tons)
Depth	650 metres
Output per wind	1·9 tons
Maximum rope speed when raising ore	15 metres per second
Maximum rope speed when raising men	10 metres per second
Weight of cage	3·6 tons
Weight of empty truck	375 kgs.
Number of waggons per cage ..	2
Number of stages...	1 (later 2)
Duration of run when raising ore	60 secs.
,, ,, with men ...	76·7 ,,
Interval between runs with ore ..	24 ,,
,, ,, ,, men...	28·3 ,,
Diameter of Koepe pulley ...	5 metres
Speed of winding engine ...	57·5 r.p.m.
Weight of rope	4·9 kg. per metre (later 7·8 kg./m.)
Permissible temporary overload.	20 per cent.
Maximum overload allowed ...	40 ,,

The winding engine is fitted with two brakes, one of which constitutes the main brake, the other being used for manœuvring purposes. Both are worked by means of compressed air. The manœuvring brake is controlled through the driver's regulating handle, while the main brake comes into play automatically when one of either the following events occur:—(1) Interruption of the excitation current—Braking occurs through the magnetic clutch placed in the exciting circuit becoming demagnetised and opening the outlet valve of the compressed air cylinder. The main brake then falls by gravity. (2) Through attaining too high a rope speed—The brake is released through a centrifugal governor fitted in conjunction with the depth indicator. (3) When the voltage drop increases beyond a predetermined amount. (4) Failure in the supply of compressed air. (5) By releasing lever placed to the left of the driver.

The essential apparatus to ensure safe working consists of a regulating gear, a depth indicator, two speed cams, and a tachometer. A description of the specified use of each of these devices may be seen in the articles previously referred to.

The Ilgner set comprises a Lahmeyer three-phase asynchronous 5,000-volt 450 B.H.P. motor directly coupled to and mounted on the same bed-plate as the continuous-current dynamo. The flywheel is mounted on its own base-plate, and is fitted with two oil pressure bearings, and an alarm bell is provided which sounds when the bearings exceed a certain temperature or the oil pressure fails by means of automatic thermometer and pressure gauge contacts. The coupling between the two units is of the magnetic type. A three-phase continuous-current 220-volt motor-generator is provided for supplying excitation. Both the machines are fitted with compensating poles. The normal speed of the Ilgner set is 750 r.p.m. The fluctuation of the speed to enable the flywheel to yield up kinetic energy for balancing the varying loads is fixed between 750 and 640 r.p.m., that is to say, between a 15 per cent. limit. As may be seen from the diagram of connections shown in Fig. 5, this speed variation is obtained by automatically increasing and diminishing the value of the resistance between the rotor phases. The principle underlying the working of the form of slip regulation employed may be described shortly as follows:—When the load comes on the hauling motor, the speed of the motor-generator set naturally drops slightly from the normal, with the result that the value of the voltage between the rotor brushes increases and serves to drive the small regulating motor *A* (Fig. 5) in the direction necessary for throwing resistance in the rotor circuit; this naturally, while decreasing the speed of the set, still further increases the voltage of the rotor, with the result that still more resistance is thrown in. When the load is taken off the hauling motor, the motor-generator reasserts itself as regards speed, and correspondingly the value of the rotor voltage drops, with the result that its pressure is no longer high enough to drive the regulation motor *A* against the direction normal to the current flowing in the second set of windings, with which it is provided. When the haulage motor is standing idle, the rotor resistances, therefore, are gradually cut out, and the flywheel set regains its normal speed. The stored kinetic energy of the flywheel is more than enough to complete a wind with a load should the current fail during working. Figs. 6 and 7 show a plan and sectional elevation of the main winder erected at the "Hain" pit.

The auxiliary electrical winding engine is driven by a three-phase 500-volt induction motor having an output of 175 B.H.P. The motor is coupled to the main driving drums through a double set of reducing gears, which reduce the speed from 600 to 32·8 r.p.m. Fig. 8 gives the starting characteristics of this motor. The speed regulation is obtained in the usual way by varying the resistances between the rotor brushes. The depth indicator, manœuvring and main brake, as well as the safety apparatus, with the exception of the eccentric cams, which cannot well be applied to a three-phase system, are the same as in the case of the main winding plant. The output and details of the auxiliary winding engine are as follows:—

Depth	650 metres
Output per wind	1900 kg.
Rope speed with ore	6 metres per sec.
,, ,, ,, men	6 ,, ,,
Weight of cage	2600 kg.
Weight of empty truck	350 kg.
Number of waggons per cage per stage	1
Number of stages	2
Duration of run	150 secs.
Time lost between runs	48 ,,
Diameter of each drum	3 m.
Gearing	1:18 (approx.)
Weight of rope	4·9 kg. per metre.

The cage of this secondary plant has a separate run from that of the main engine, with the result that they can be used simultaneously. In such a case the hourly output of the pit is increased to 113 tons, which output, when the second continuous-current winding motor for the main engine is erected, will be increased to 195 tons per hour.

Two high-tension cables are provided for carrying energy down into the workings of the pit. Here the energy is transformed down to 500 and 115 volts for hauling, ventilating, drilling, and lighting puproses. It may be mentioned here that the maximum circuit-breakers are fitted in all cases with time-limit relays on the train-of-wheels principle, and are set for six seconds. The incoming cables are also provided with reverse current relays on the wattmeter system. As the mines have only lately been developed, the underground plant is not as yet very extensive; plans, however, are being prepared for the electrification of the underground roadways as soon as these are of a length warranting the use of electric machinery. Above bank a great many small motors are used for driving the forge, the smithy, the workshops, and the saw-mills. In addition, there is a three-phase asynchronous 5,000-volt 65 B.H.P. motor for driving the aërial ropeway, which serves to transmit the product of the mine

Digitized by Google

straight away in the same trucks as are used underground to the chemical factory over a distance of about three miles.

The Felten & Guilleaume-Lahmeyerwerke were responsible for the electrical equipment of both the main and auxiliary winding engines of this pit. The subcontractors for the mechanical part of the latter were the Zwickauer Machine Co.

The Electrical Equipment at the Immenrode Pit.—The chief electrical equipment of this pit consists, as in the case of the Nordhauser Kali Co.'s "Hain" pit, of a main winding engine on the Lahmeyer-Ilgner system and two secondary winders driven by three-phase motors. One of the latter is at present being used for completing the sinking of a new shaft. The main winding engine is directly driven by a continuous-current motor fed from a three-phase continuous-current motor-generator flywheel set. The safety and braking devices are the same as in the case of the main winder erected at the "Hain" pit, with the exception that

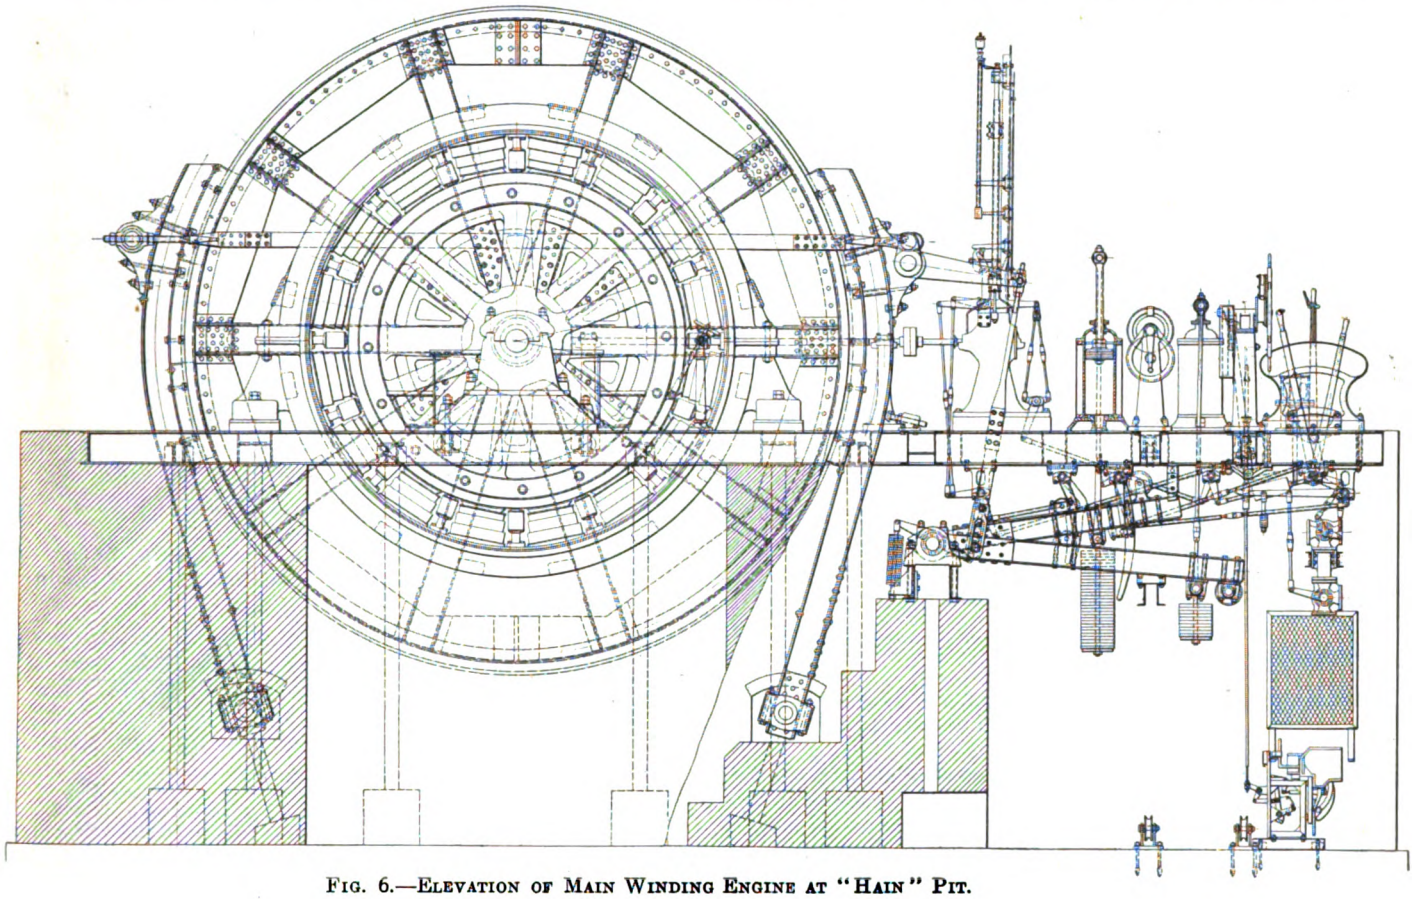

FIG. 6.—ELEVATION OF MAIN WINDING ENGINE AT "HAIN" PIT.

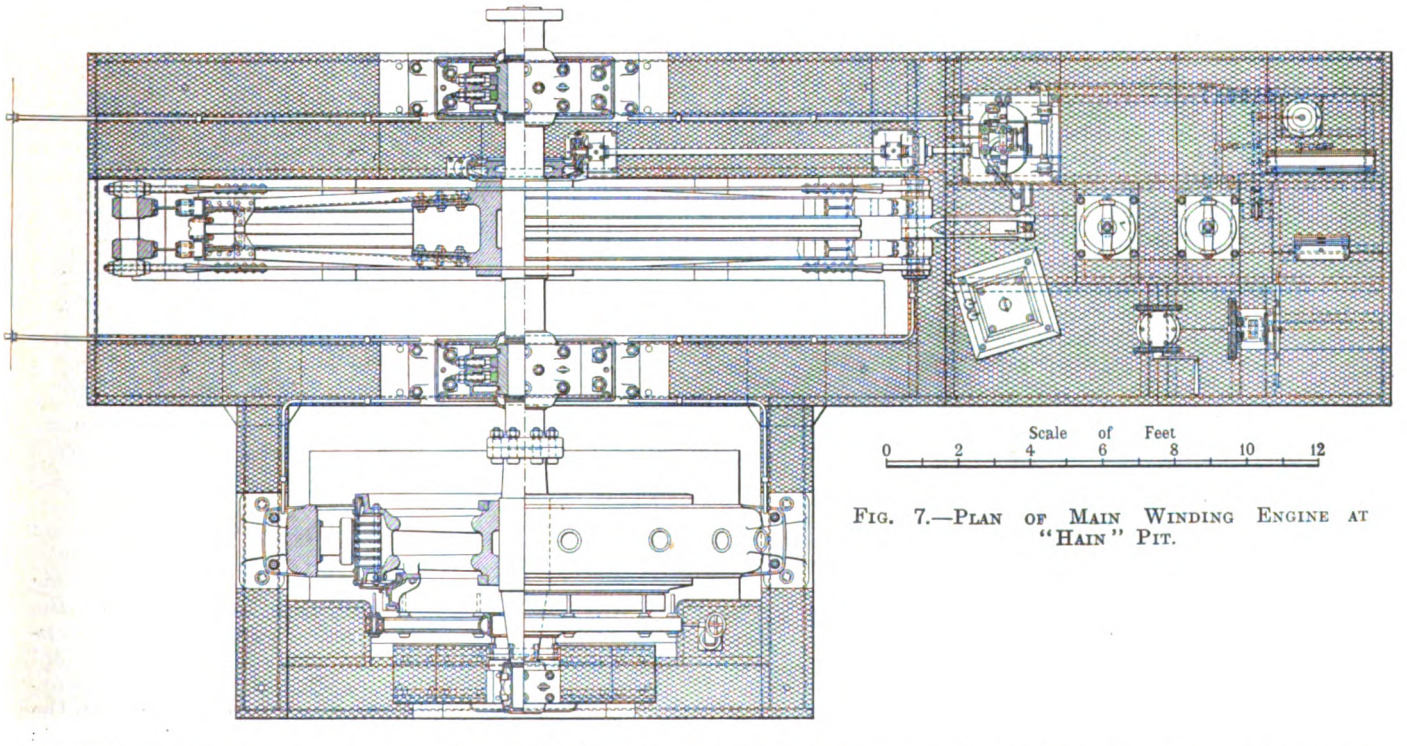

FIG. 7.—PLAN OF MAIN WINDING ENGINE AT "HAIN" PIT.

Digitized by Google

electro-magnetic brakes take the place of those actuated at the " Hain " pit with compressed air. The motor-generator set comprises a three-phase asynchronous 5,000-volt motor with an output of 520 B.H.P. at 500/425 r.p.m., and a continuous-current dynamo with compensating poles arranged for separate excitation

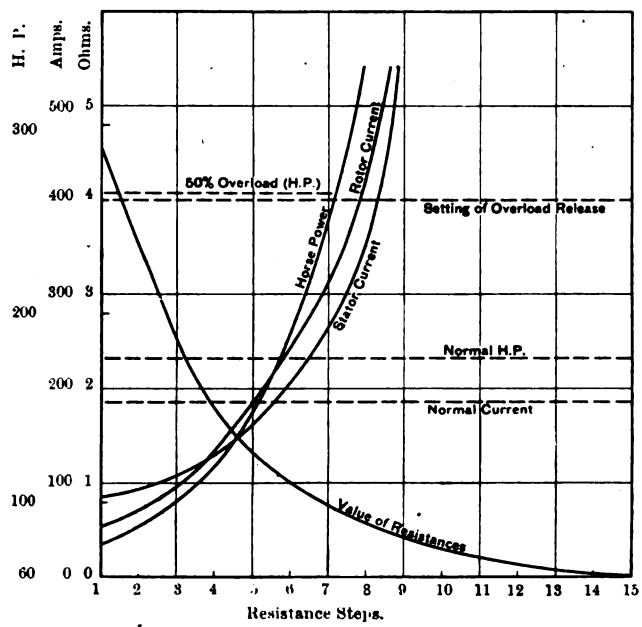

Fig. 8.—Characteristic Curves of 175-h.p. Induction Motor of Auxiliary Winder at Hain Pit.

and capable of delivering energy sparklessly at a pressure of from 0/500 volts. The flywheel is made in one solid piece, with a diameter of 3·5 metres and a weight of 33,500 kgs. The continuous-current driving motor is also provided with compensating poles, and is separately excited from a small 220-volt motor-generator set. The speed of the winding motor is 44·6 r.p.m. The output of this plant, with a rope-speed of 14 metres per second and a Koepe pulley of 6 m. diameter, is 3,200 kgs. per wind. The depth of the pit on completion of the sinking operations will be approximately 1,000 metres. The auxiliary winding gears at this pit are driven by three-phase 5,000-volt asynchronous motors, each with a normal output of 175 B.H.P. when running at 600 r.p.m. The speed regulation is by means of a variable resistance inserted in the rotor circuit. The safety and braking appliances are similar to those used with the auxiliary winding plant at the " Hain " pit. The horse-power curves of one of these motors working under various conditions are shown in Fig. 9, from which also the acceleration and running period per wind may be seen. That and Fig. 10 give the starting characteristics. In addition to the main and secondary winding units described above, there are erected at this pit two high-tension 5,000-volt asynchronous three-phase motors each of 165 B.H.P., used for driving, through belting, two Rideau fans. There are also a number of small motors up to 35 h.p. in use for various purposes. These are driven from 500-volt circuits supplied by two 150 k.v.a. transformers. The latter, as well as one of the 100 k.v.a. capacity, are employed for reducing the incoming pressure of 5,000 volts down to 500 and 110 volts respectively. The latter is used for the lighting circuits.

The Electrical Equipment at the Ludwigshall Pit.—The electrical equipment of this pit consists at present only of a few small motors for the workshops, &c., and the lighting. The main and auxiliary winders are at present driven by steam, as the company had in their possession two comparatively new steam engines which had originally been at work at one of the pits which has recently been shut down. Arrangements are shortly to be carried out whereby high-tension circuits will be taken down the pit for power and lighting purposes.

The Electrical Equipment of the Chemical Factory.—The supply of electricity for power purposes in the chemical works is obtained direct at 5,000 volts over three cables from the adjoining central station. The distributing and transforming centres are three in number, and, as mentioned before, one is provided for the rolling mill, one for the drying plant, and the third in connection with the dissolving tanks. The motors

for driving the rolling mills comprise three high-tension 5,000-volt asynchronous motors having an horse-power together of 375. Further motors aggregating some 175 h.p. are employed for the lifts, elevators, and the distributing gear. These run on the low-tension circuit. 5,000-volt motors are used for the stirring apparatus (60 h.p.), the pumps (75 h.p.), and the conveying bands (100 h.p.) in the dissolving house; but the smaller motors up to 35 h.p. used for driving the lifts (24 h.p.), small elevators (70 h.p.), and the sifting motors are all connected to the low-pressure circuit. The electrical equipment in the drying house consists only of low-tension motors for driving the elevators (110 h.p.), pumps (50 h.p.), drying pans (50 h.p.), tippers (35 h.p.), and conveyors (12 h.p.). The horse-power

Digitized by Google

connected to the high-tension side of the system and at work in the factory amounts to 610 B.H.P., and the low-tension horse-power to 571, making a total of 1,181 B.H.P., practically all of which is at work continuously on a day and night load.

In conclusion, the writer's thanks are expressed

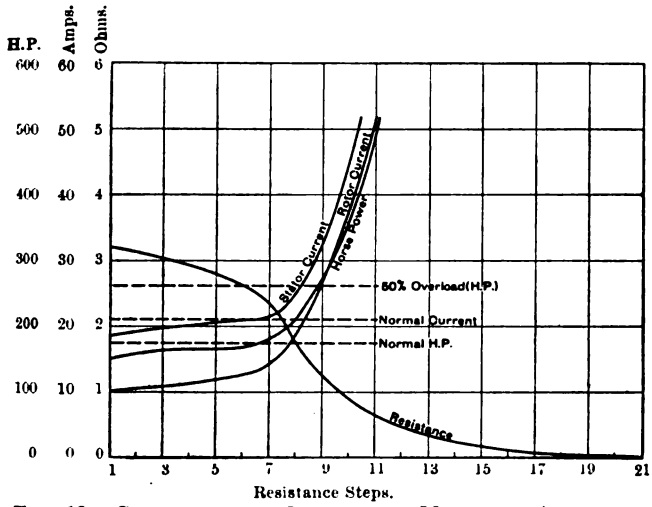

FIG. 10.—CHARACTERISTIC CURVES FOR MOTOR OF AUXILIARY WINDER AT IMMENRODE PIT.

towards the directors of the companies who have kindly allowed him to publish the details of the installation, and to the firms who have courteously placed at his disposal the drawings and photographs, from a selection of which the illustrations have been prepared.

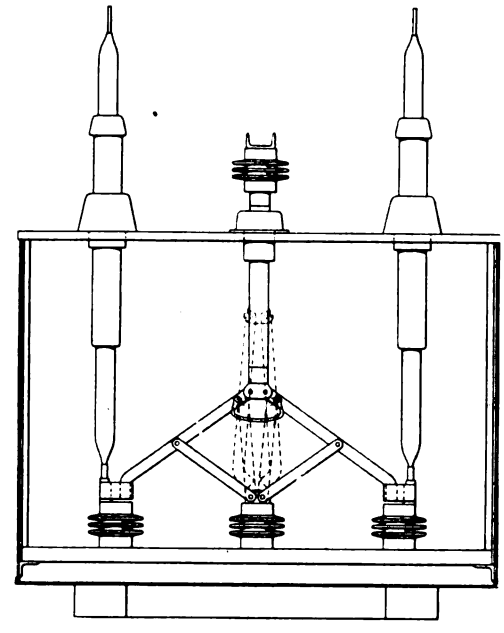
British Association.—The provisional programme of Section G (Engineering) for the forthcoming meeting at Dublin has now been issued, and announces the following Papers:—*Thursday, September 3rd:* Address by the President of the Section, Mr. Dugald Clerk, F.R.S. *Friday, September 4th:* Report of the Committee on Gaseous Explosions to be read and discussed in joint meeting with Sections A and B. *Monday, September 7th:* "Recent Advances in Steam Turbines," by G. Stoney; "Producer Gas," by P. Emerson Dowson; "Suction Gas Producers," by P. W. Robson; "The Utilisation of Peat for Making Gas or Charcoal," by Captain H. Riall Sankey. *Tuesday, September 8th:* "The Laws of Flight," by F. W. Lanchester; "The Causes of Wear in Motor Vehicle Machinery," by F. H. Royce; "On a Fundamental Error in the Theory of Power Transmission by Belts," by W. Worby Beaumont. Other Papers to be read:—"A Clock-driving Mechanism for Equatorial Telescopes," by Sir Howard Grubb, F.R.S.; "Experiments on Rotating Discs," by J. Brown, F.R.S., and Maurice F. Fitzgerald; "Strength of Solid Round-ended Columns," by W. E. Lilly; "Railless Traction," by F. Douglas Fox; "On the Study of Breakages," by W. Rosenhain.

Train Lighting in Australia.—In a recent issue of the *Australian Mining Standard*, the following notes, from a Paper read by Mr. D. C. Jackson, before the Western Society of Engineers, are given. There are three systems of electric lighting on the railways. In the first system steam-driven generators are employed; in the second generators under each car are driven from the car axles; and in the third storage batteries are placed on the cars, and are charged when the cars are not in use. For the first system turbine sets are now mostly in favour, owing to the vibration caused by reciprocating engines. Tests of steam consumption show results varying from 60 lb. to 90 lb. per kilowatt-hour. In connection with axle-driven generators, some typical test figures on the Northern Pacific Railway are as follows:—Duration of test, 31 hours; train above cutting-in speed and generator in operation 23½ hours; lamps lighted 13½ hours; generator output, 28·6 kilowatt-hours; lamp consumption, 14·6 kilowatt-hours; battery charge, 12·2 kilowatt-hours; battery discharge, 4·7 kilowatt-hours; average generator efficiency, 80 per cent.; power absorbed from axle (taking 3 perectnt. loss in belt) 2·1 horse-power. The total efficiency for the test (*i.e.*, ratio of lamp consumption to mechanical energy) is, therefore, slightly under 40 per cent. The third system is the simplest, but requires expensive charging stations. It is most economically operated on short runs, where there is heavy traffic and many cars are so equipped. Even then it is doubtful if it holds its own against the axle drive. Steam-driven generators come next as regards simplicity, but require a considerable amount of attention.

CIRCUIT-BREAKER FOR 75,000 VOLTS

A DESCRIPTION is given in the *Western Electrician* (Chicago) of some 75,000-volt circuit-breakers which have been installed in the sub-stations of the Edison Electric Company's transmission line from Kern River to Los Angeles, and which are said to be the first 75,000-volt automatic oil circuit-breakers operating without the use of series transformers that have been placed in service on any transmission system.

The accompanying illustration shows the construction of the switch mechanism, the movable contacts, which are of the knife-blade type, being part of a simple pantograph, the lower portion of which is pivoted to the metal cap of the central insulator and the upper part to the end of a wooden rod which is attached to a special porcelain insulator secured to the channel iron crossbar. A vertical movement of the cross-bar imparts a horizontal movement to the ends of the blades as they leave the contacts, these ends being brought together in the centre of the tank in the open position of the switch, as shown by the dotted lines. The cross-bar is carried on two guide rods placed in cast-iron frames between the tanks, the vertical movement



OIL SWITCH FOR 75,000 VOLTS.

being given to it by means of a rocker shaft beneath the central tank having two arms which are connected to the lower ends of the guide rods by means of links. The counterweight is also mounted on the rocker shaft. Coil springs for opening the breaker when tripped are placed in each frame, where they operate directly on the guide rods. The tanks are of iron and the covers of marble, made in two pieces, either one or both of these pieces being removable for purposes of inspection without disturbing any other part.

The circuit-breakers are arranged for hand closing, the handle being carried loosely on the rocker shaft and connected to the closing mechanism by means of a short lever and a dog, the dog being released by the action of the tripping mechanism in the event of an overload or short circuit. The tripping mechanism, which is very simple in design, is set in motion by any one or any two of the trip coils independently or by all of them acting together, and is automatically reset each time the breaker opens. The trip coils consist of a few turns of small diameter and are placed directly in the line, being suspended from the insulators of the disconnecting switches and supported by the connection to the switch terminals. The insulation of the coil has a very long creepage surface, approximately 60 in., and a dielectric strength of at last three times the line voltage, thus giving it a higher factor of safety than that of the best series transformer.

Electric Railways in the Alps.—A firm of engineers in Basle has, according to the *Schweizerische Elektrotechnische Zeitschrift*, applied for concessions for the construction and operation of an electric narrow-gauge and cable railway connecting St. Moritz, Silvaplana, and Pontresina. The proposed railway is divided into four sections, two of which are steep gradient cable railways. The other sections will be provided with a service of accumulator cars. The total cost is estimated at £144,000, or £7,120 per kilometer.

THE MARSEILLES ELECTRICAL EXHIBITION

A DESCRIPTION of some of the principal exhibits in the Palais de l'Energie at the Marseilles Electrical Exhibition is given in *La Revue Electrique*. As already stated in a previous article (Electrical Engineering, July 30th, p. 181) most of the exhibits relating to the heavier branches of electrical engineering are contained in this part of the exhibition.

The exhibits relating to cables appear to be fairly representative, especially as regards impregnated paper cables for high tensions, jute cables for low tensions. There are indications of the tendency to a disappearance of concentric cables, their place being taken by those with two, three, or even four separate cores. Cables are shown, as well as other exhibits of switchboards and telephone apparatus, by the Société Industrielle des Téléphones, and another interesting cable exhibit is that of the Société de Cables Electriques Berthoud-Borel et Cie, who show actual cables under test at 100,000 volts alternating and intermittent unidirectional voltage of over 300,000, obtained by a synchronous revolving contact-maker, designed by M. Delon, which connects the cores of the cable successively with the high-tension transformer in such a way that the voltage waves to which each core is subjected are always in the same direction. Aluminium as well as copper wires and cables are exhibited by the Tréfileries et Laminoirs de Havre. It is interesting to note in this connection that long aluminium power lines are coming into use in Europe, as well as in America, notable examples being found in Bulgaria in a line for the supply of Sofia, and in the South of France on the Mediterranean coast. Apart from questions of the relative prices and conductivity of the two metals, advantages are claimed for aluminium over copper in respect of the lighter supports required to sustain its weight, and its lower coefficient of expansion, although the surface offered to wind pressure is greater. Also, as the diameter of an aluminium wire is greater than that of one of copper of equal conductivity, the inductance of the line is less, and there is less loss from "silent" discharge.

We have already mentioned the electric lorry worked by Edison accumulators, shown by the Bergmann firm. These vehicles are constructed to carry a load of 2 tons at 7½ miles per hour, with a range of about 35 miles, and are provided with a 64-cell battery, with a capacity of 14 kw.-hours. A description of the German form of the Edison iron-nickel alkaline storage battery was contained in Electrical Engineering, Vol. III., p. 695. The cells can be charged in 3 hours and 45 minutes at 65 amperes. It is stated that several of these vans are in experimental use.

Accumulators of the more familiar lead type are shown by the Compagnie Française de Accumulateurs "Union," who have on view specimens of the large cells, such as are used in batteries on tramway systems. Examples of these in actual use are a 6,000 ampere-hour battery at Bordeaux, and a battery for 1,870 ampere-hours in use on the Marseilles tramway system. The French Tudor Co. also exhibit their well-known cells, and show the Soulié vibrating tongue rectifier for charging batteries from alternating circuits. Small ignition batteries are also shown by several makers.

In the section devoted to generators, motors, transformers, &c., many well-known French, Swiss, and other firms take part, most of whom show standard machines of this nature. It is only possible here to call attention to a few of the special exhibits, which present points of novelty or special interest on a few of the stands. A new single-phase commutator motor, the speed of which can be varied by shifting the brushes, is shown by Messrs. Brown-Boveri & Co., and this is used to drive another exhibit, consisting of a special train lighting dynamo, used in conjunction with accumulators. Among the exhibits of another well-known Swiss firm, the Société Aloith, of Basle, are single-phase and three-phase rectifiers on the permutator principle of the system of Messrs. Auvert and Ferrand, the traction form of which is on view on the stand of the P.L.M. Railway in the Palais de Traction. The Fynn-Alioth single-phase motor is also shown. The Bergmann Co. demonstrate their system of printing press driving. The well-known Thury system is represented by a high-tension continuous-current generator, with constant current regulator, driven by a three-phase motor.

Among the large machines shown is a fine vertical shaft three-phase 1,750-kw. 5,500-volt alternator, with 56 poles, for running at 107 r.p.m., manufactured by the French Thomson-Houston Co., and one of eight, made for the power-house of the Société Energie l'Electrique du Sud-Ouest at Tuillière, on the Dordogne. Other exhibits of the same company include mercury-vapour rectifiers and aluminium electrolytic lightning arresters. Another large machine to which attention should be drawn is a 1,100-kw. double-current interpole generator of the Société Alsacienne, of Belfort, for driving by a Pelton wheel. This machine, which runs at 375 r.p.m., generates at 850 volts on the continuous-current side, and 510 volts 25 cycles on the alternating-current side. It is destined for use on the tramway system between Villefranche and Bourg-Madame in the Pyrenees, where the continuous-current side will feed the section of the line near the station, while the current from the alternating side will be stepped up to 10,000 volts for transmission to a distant sub-station. A similar system is in use on the Marseilles tramway system. The French branch of the A.E.G. Co. show a great variety of apparatus, amongst which may be noticed a compact 10-kw. steam turbo-generator for torpedo-boat lighting, train lighting sets on the Rosenburg system, and examples of mercury-vapour lamps in quartz tubes. (See Electrical Engineering, Vol. II., p. 549.) The lamps shown have straight horizontal tubes from 3 to 6 in. long, with bulbs at the ends for the mercury electrodes, provided with cooling ribs. Ballast resistances similar to those used with Nernst lamps are employed. The lamps are made for 3·5 amperes at 220 volts, and 4 amperes at 110 volts, and it is said that the light given is intermediate in appearance between that of the Cowper-Hewitt lamp and the ordinary open arc.

The applications of electric power exemplified cover a considerable range, including cranes, hoists, capstans, conveyors, fans, pumps, and portable tools, and the adaptation of electric motors to the driving of a variety of industrial machinery. Prominent among these are the electrically-driven looms shown by the Compagnie Electrique de la Loire, and in this connection it is interesting to note that of the 28,000 looms in the weaving districts of the department of the Loire and Haute Loire, no fewer than 15,000 are driven electrically by the company, with motors varying from 1 to 1·5 b.h.p.

Other exhibits to which attention should be drawn are steel and concrete poles for transmission lines. These latter are shown by the Société des Ciment prompts et Portland Artificiels de Grenoble. These poles are made on the Delamarchi system, and over 8,000 are already in use in the neighbourhood of Grenoble. It is said that under test one of the reinforced concrete poles, 12 metres high, when loaded at the end horizontally with a pull of one ton, gave a deflection of 60 mm. without breakage 42 days after completion.

High-tension switchgear and apparatus is also well represented, but no great note of novelty is struck. The examples of condensers of the Moscicki type are (Electrical Engineering, Vol. I., p. 565) shown under test pressures of 30,000 volts, alternators should, however, be mentioned. Reference was made in our previous article of the various power companies in different parts of France, including the large relief map of the latest scheme of Messrs. Blondel, Harlé and Mahl, for the supply of electricity to Paris generated by the river Rhône. This scheme is for the utilisation of a fall of 70 metres available at Génissiat, where a 350,000-h.p. station is proposed, transmitting power at 120,000 volts, three-phase, 25 cycles, and at the same time vastly improving the navigability of the river right up to Geneva.

The electrometallurgical and electrochemical section is also of interest, and contains samples of electrically-prepared materials and models of electric furnaces and other apparatus.

A Curious Accident.—A daily paper reports from Basle that a young man, who was flying a kite with an aluminium wire instead of the customary string, was killed through the wire coming in contact with some high-tension overhead conductors.

Melbourne Telephone System.—The work of laying underground the telephone wires of Melbourne is being actively carried on. When completed, the total length of tunnels, according to the *Australian Mining Standard*, will be about 2½ miles. The tunnels are from 25 to 30 ft. from the surface, and the inside measurement is 6 ft. 6 in. high by 4 ft. 6 in. wide. The cables will be carried along the walls on hooks. The magnitude of the undertaking is suggested by the computation that when the whole of the tunnelling has been excavated something like 40,000 tons of material will have been brought up. Access to the tunnels will be gained by means of manholes at intervals along each route, and ventilation is provided for by 9 in. pipes, which will reach the footways. The underground operations are being carried out by electric light, and electric power is employed for the winding gear at the top of the shafts. On the new common battery switchboard, which is to be installed in the new exchange, there will be 90 operators' positions; of these 21 will be devoted to incoming junction lines, and 69 for incoming subscribers' lines. The ultimate capacity of the board will be 11,700 subscribers' lines, but the equipment supplied will be for only 9,000. But as there are at present only about 5,000 subscribers to be provided for, a margin is left for future enrolments for a considerable time. The department already has common-battery switchboards at Sydney and at Hobart, but these are very much smaller than that which is contemplated for the new Melbourne Exchange.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

ONE of the disadvantages of the electrothermal oxidation of the atmosphere in order to obtain nitric acid is the difficulty in producing it in a concentrated form. It might be supposed that by simply distilling the dilute acid obtained from the absorption towers the concentrated acid could be obtained; this, however, is not the case. Nitric acid of about 40 per cent. strength passes over on distillation at a constant temperature, and therefore no separation from water ensues. The Badische Anilin and Soda Fabrik have endeavoured to get over the difficulty by passing the gases from the electric furnace through hot tubes; this decomposes the higher oxides, and when the gas is subsequently absorbed by caustic soda sodium nitrite is obtained. But there is only a limited use for sodium nitrite in the organic dye and similar industries. As a fertiliser it is no good, but, on the contrary, is harmful, and one of the chief objects in fixing atmospheric nitrogen is to produce fertilisers. B. F. Halvorsen, of Christiania, in the American Patent 892516 (1908) claims to be able to produce it by dissolving the oxides of nitrogen in concentrated sulphuric acid, thereby forming nitrososulphuric acid. This upon decomposition with water, would, under ordinary conditions, produce nitric oxide, which would go off as a gas. But by the terms of the patent the nitrososulphuric acid is treated with water and an oxidising agent, such as ozone, hydrogen peroxide, manganese dioxide, lead peroxide, or chromic acid. The nitric acid can then be distilled off from diluted sulphuric acid, and the oxidising agent regenerated by means of an electric current. Would it not, however, be possible to oxidise the nitrosulphuric acid in the first place electrolytically, and thus avoid the addition of outside oxidising agents?

In the American Patent 890084, of F. W. Morris, an electrolytic method for preparing aluminium oxide in a form suitable for employment in the electric furnace is described. The crude earthy material containing aluminium compounds is treated with sulphuric acid. This converts the aluminium compounds into aluminium sulphate. The solution, which also contains the sulphates of other substances, such as iron, is run off from the insoluble gangue. It is then, after filtration, placed in the anode compartment of an electrolytic cell, the cathode compartment being charged with a solution of sodium chloride. On electrolysing, the aluminium ions, together with the ions of other metals of the same group, pass through to the cathode. Here the aluminium and iron and calcium will not be deposited out as metals, but are thrown out as hydroxides. The sulphuric anion remains in the anode compartment and chlorine from the sodium chloride will also pass into this compartment. The sodium ions will be discharged in the cathode compartment, which will in course of time become strongly alkaline. The alkali hydroxide formed will dissolve the aluminium hydroxide, forming sodium aluminate, but will have no action on the iron and calcium hydroxides, which will remain in suspension. When the electrolysis is finished, the sodium aluminate solution with excess of sodium hydroxide is filtered off from the insoluble hydroxides. It is then evaporated to dryness and calcined. This decomposes the sodium aluminate into alkali and aluminium oxide, which, owing to the calcination, is practically insoluble in the sodium hydroxide solution obtained when it is subsequently leached out with water. The sulphuric acid which was regenerated in the anode compartment can be again employed for leaching out a fresh quantity of aluminium earth. The presence of chlorine, produced by the electrolysis of the sodium chloride, will probably facilitate the dissolving process.

In the *Mining Journal* of August 15th Edmund Spargo contributes a letter upon the "Latest Electric Process for the Direct Extraction of Copper and Iron from their Ores." He incidentally refers to the Cowper-Coles process, and Mr. Coles' prophecy that it will not be long before copper will be produced by electrolytic means directly from its ores. Mr. Spargo states that a process for the production of copper directly from its ores has been in operation for about two years, during which time ore of almost every grade from that containing 50 per cent. to that which only contains 1·74 per cent. of copper have been treated, and apparently with satisfactory results. The process consists of four operations, crushing, roasting, lixiviation, and, finally, deposition, no smelting being required. The ore is first crushed, and, after being mixed with a certain proportion of iron, is roasted in an electric or other type of furnace (we wonder whether an electric furnace has been actually employed). The sulphurous gases produced are taken to a chamber and converted into sulphuric acid. This treatment of sulphurous gases is so often suggested, but so rarely actually done, that one would like to know whether this is more than a paper suggestion. The ore, after roasting, is automatically conveyed to lixiviating tanks, which are arranged so as to facilitate removal of the residues. An important point one would very much like to know is, what is the lixiviating solution—is it the sulphuric acid previously made in the chambers from the sulphurous gases?

The copper solution then passes into the depositing tanks, where it is converted directly into tubes and sheets, the latter being about 40 in. square and 100 lb. in weight. The copper is directly marketable. A quantity of the company's ore at Coniston has recently been treated, and pure electrolytic copper obtained at a cost of £12 10s. per ton, and this product was immediately sold at £62 10s. per ton. The company holding the patents is the Annandale Copper Mines and Smelters, Ltd., the inventor of the process being Mr. T. Scott Anderson.

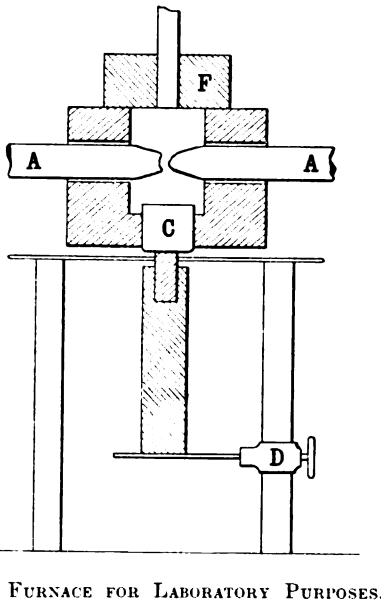
At Coniston there are waste and dump-heaps estimated to contain 200,000 to 300,000 tons, having a copper content of 1·5 to 2 per cent. of copper, and it is claimed that these can be profitably worked by this process. Water power exists on this property, and is included in the company's lease. The Annandale Copper Mines Co. has a nominal capital of £200,000, of which £40,000 is being immediately provided to work the Coniston property.

It is sincerely to be hoped that it will be found feasible to extract copper directly from such poor products as those containing 1·5 to 2 per cent. of copper, but previous experience hardly tends to make one sanguine. Messrs. Siemens & Halske had a very—on paper—good process for extracting copper ores which was actually worked for some time, but it was not found possible to make a commercial success of it. One of the main difficulties to be overcome is the great loss of the leaching liquid in the process. This usually dissolves a great deal more than the copper, and even if these impurities are not deposited along with the copper, they at any rate use up the leaching solution.

According to Mr. Spargo, Mr. Anderson has also a successful process for smelting hæmatite or magnetite iron ore directly in the electric furnace. The ore, mixed with certain proportions of limestone and charcoal, is charged direct into the furnace, and the current switched on. The power required to produce one ton of high grade pig-iron from the ore is 300 h.p. for six hours. By a second operation the pig-iron so produced can be refined to steel of any desired grade.

In the *Electrochemische Zeitschrift* of August Louis Clerc and Adolphe Minet describe a "New Electric Arc Furnace for Laboratory Purposes." When working upon the electric arc for furnace purposes, they found that an arc could be maintained when the electrodes were several centimetres apart, with a current of 40 amperes and a pressure of 50–60 volts. The conditions necessary are to have the diameter of the furnace space corresponding to a certain energy or to a given size of arc. The greater the current density the larger the diameter may be. When the arc is once formed it does not go out by pushing a conducting crucible of graphite or a non-conducting crucible of magnesia into it and the electric constants, current, and potential show very little variation.

The furnace consists of two chief parts, *A A* and *F*, made out of fire-resisting material, such as lime or magnesia. The



Arc Furnace for Laboratory Purposes.

block, *A A*, has a cylindrical hole bored through it to take the electrodes, and from the top a wider cylindrical hole to act as furnace space, this latter having a diameter of 3 cm. and a height of 6 cm. The electrode holes have a diameter of 2 cm. *C* is the crucible in which the reactions are caused to take place. It can be raised or lowered by the ratchet arrangement at *D*.

By employing an energy of 1–2 kilowatts one can carry out a

Digitized by Google

variety of observations with this furnace. For example, by keeping the crucible in the position shown in the diagram, reactions can be studied at a low red heat. By pushing the crucible further up so as to be just below the electrodes and drawing them further apart in order to increase the length of the arc, a white heat can be obtained. Finally, by drawing the electrodes still further apart, and pushing the crucible up so that it is in the centre of the electrodes, reactions at the full temperature of the arc can be studied. The electrodes can be drawn out right to the edges of the furnace without the arc being extinguished.

In part ii. of the article Minet describes experiments which he has carried out in order to determine what are best conditions to employ for various classes of work when the arc is enclosed in a small space. Under these conditions so many considerations have to be taken into account. For example, the nature and thickness of the enclosing walls, the form and dimensions of the electrodes, the thickness and length of the arc required, its temperature, the pressure of the gas mantle in which it burns, the potential and the strength and density of the current, the specific resistance of the vapour produced by the reactions, and so on. All of these Minet has endeavoured to study, but in the present article he only touches the fringe of the subject.

Resistance of Spark Gaps.—In the current number of the *Proc., Roy. Soc., Edin,* R. A. Houstoun gives an account of some measurements that he has made of the resistance of spark gaps, using the method, due to Bjerknes, of taking resonance curves. The oscillating circuit consisted of a condenser, the opposite plates of which were connected by thick copper wires to the electrodes, which were cylindrical, about 4 mm. diameter, 3 cm. long, and had rounded ends. The resonator was made in Drude's form, two parallel tubes, 2 cm. apart, their lower ends being attached to the opposite plates of a condenser; into these tubes rods slide, the upper ends of which were joined by a platinum-constanstan thermocouple connected to a d'Arsonval galvanometer. The length of the resonator could be varied from 58 cm. to 100 cm. The oscillator was excited by means of an induction coil, and the length of the resonator altered until a maximum deflection on the galvanometer was obtained; deflections were then taken for different lengths on both sides of resonance. For such circuits Drude has shown that

$$\gamma_1 + \gamma_2 = \pi \frac{\delta a}{a_m} \sqrt{\frac{J}{J_m - J}}.$$

where J_m is the maximum deflection, a_m the corresponding length of the resonator, J is the deflection for the length $a_m \pm \delta a$, and γ_1 and γ_2 are the logarithmic decrements of oscillator and resonator. Knowing the resistance, inductance, and capacity of the resonator γ_2 could be calculated, and substracting this from $\gamma_1+\gamma_2$, γ_1 found, from which the resistance of the oscillator was obtained. The gaps were varied from 0·4 mm. to 2·4 mm., and eight different metals were used as electrodes, viz., Zn., Al., Cd., Sn., Cu., Fe., Ni., and brass. The smallest resistance recorded was about 5 ohms, but the results are not very consistent. With Al. there is a remarkable decrease of resistance with increase in length of gap, and Zn. always gave a larger resistance when freshly cleaned.

Heusler's Magnetic Alloy.—Since 1903, when Heusler made the discovery that alloys of copper, aluminium, and manganese are strongly magnetic, many Papers have been published dealing with their properties. In the *Proc., Roy. Soc., Edin.*, just issued, J. G. Gray describes some interesting experiments made with an alloy containing 25 per cent. manganese, 12·5 per cent. aluminium, a trace of lead, and the rest copper. He investigated (1) its magnetic properties at temperatures between 0° C. and 400° C.; (2) alteration in magnetic properties brought about by heating and cooling; (3) magnetic properties at the temperature of liquid air after the specimen had been heated and quenched. The magnetometer method of testing was used, the specimens being cylindrical. They were heated electrically in a coil of thin platinum wire wound non-inductively. The specimen was taken through a cycle at the temperature of the room, then heated, and the cycle gone through at various temperatures. The effect of increase of temperature is to diminish continuously the permeability and hysteresis of the material; at 310° it became practically non-magnetic. Next the magnetic field was kept constant, and the temperature gradually increased until the magnetometer deflection became zero; the specimen was then allowed to cool, and magnetometer readings taken. The cooling curve does not coincide with the heating curve, and the difference is most striking when the applied field is weak, the magnetic quality being to some extent destroyed. Subsequent heating and cooling results in a further diminution of magnetic property, and so far as the experiments went there is no appearance of a limit to this. The magnetic properties, when the specimen is quenched from a high temperature, are very remarkable. In the quenched condition it is almost non-magnetic at the ordinary room temperature, but on cooling to the temperature of liquid air, its permeability was much greater than that of the material in the normal or unquenched condition.

Continental

Liquid Anodes.—It is well known that it is impossible to maintain an arc between a cold cathode and a hot anode. The cathode must be hot in order to allow the necessary quantity of electrons to escape through the potential gradient due to the electric double layer at the surface. In the *Comptes Rendus* for August 3rd, G. Athanasiadis studies the conditions under which an arc can be formed between a method and a liquid, more especially in connection with the arrangement adopted in Duddell's singing arc. If a copper-wire 1 mm. in diameter is plunged into a dilute sulphuric acid in which a carbon plate is immersed to form the other electrode, the phenomena observed on applying a high voltage differ greatly according to the direction of the current. When the wire is an anode, and is plunged some 5 c.m. into the liquid, the end of the wire becomes phosphorescent, and the current, rising at first to about 6 amperes, falls to half an ampere, owing to the polarisation of the wire. The current then remains constant, even if the voltage is raised to 220. A white vapour escapes from the anode, owing to the decomposition of the sulphuric acid. On reversing the current an arc is formed, with the wire as cathode, and the latter is rapidly melted. The arc may be obtained also with tin, aluminium, carbon, and other cathodes. Some interesting phenomena are obtained when thicker wires are used. A copper-wire 3 to 4 mm. in diameter, used as an anode, is polarised by bringing its end into contact with the liquid and then slowly submerging it to the extent of 2 or 3 cm. On reversing the current an arc forms round the submerged end of the wire, accompanied by a loud sound and the projection of drops outside the vessel. On increasing the voltage to 220 the current may rise to 8 amperes. The arc is made more brilliant, and the pitch of the sound higher by shunting a capacity of 10 or 20 microfarads across it. This capacity has, however, no effect upon the polarisation of the wire when used as an anode. The effect of the condenser is diminished by inserting inductances in both the parallel circuits. The rate of interruption is 50 to 180 per second, so that something like Duddell's phenomena may be obtained with a liquid anode. It is important to notice that the cell described acts as a valve or rectifier up to voltages of 220. This action is greatly favoured by the incandescence of the wire.

Meteorological Reports by Wireless Telegraphy.—The annual report of the Royal Meteorological Society states that the arrangement for the transmission of reports by wireless telegraphy from his Majesty's ships has been in operation throughout the year, and 146 wireless telegrams were thus received. The greatest number received in any one day was nine. Occasionally, however, no messages were received for several days. Messages were received chiefly from ships crossing the Bay of Biscay, and on many occasions the information has formed a useful supplement to the usual reports from the land stations. In compliance with a request from the International Conference at Innsbruck, a report was prepared for presentation to the International Meteorological Committee at Paris upon the terms upon which reports by wireless telegraphy are available from ships of the mercantile marine. It was estimated that the cost for an adequate number of wireless telegrams to be of practical service in supplementing the land observations for purposes of forecasting and storm warnings would amount to about £1,000 per annum.

The Iron & Steel Institute.—The following are among the Papers down for reading at the forthcoming meeting of the Iron & Steel Institute at Middlesbrough, on September 28th–30th and October 1st and 2nd :—On the scientific control of fuel supply, by Prof. H. E. Armstrong, F.R.S.; on gas-producer practice, by Prof. W. A. Bone, F.R.S., and Dr. R. V. Wheeler; on the production of finished iron sheets and tubes in one operation, by S. O. Cowper-Coles; on some results of experience with electrically-driven rolling mills, by C. Koettgen and C. A. Ablett; on electric power supply, by C. H. Merz; on a test for ascertaining the relative wearing properties of steel rails, by E. H. Saniter. A number of visits to works will be paid, including those of Messrs. Bolckow, Vaughan & Co., Messrs. Dorman, Long & Co., the Linthorpe-Dinsdale Smelting Co., the Cargo Fleet Iron Co., Messrs. Bell Brothers, Ltd., the North-Eastern Steel Co., the Skinningrove Iron Co., Ltd., Sir B. Samuelson & Co., Messrs. William Whitwell & Co., Richardsons, Westgarth & Co., the Darlington Forge Co., the electric power stations erected by the Cleveland and Durham Electric Power, Ltd., and by the Newcastle-upon-Tyne Electric Supply Co., Ltd., the Tees Dockyard of R. Craggs & Sons, Ltd., the Cleveland Dockyard of Sir Raylton Dixon & Co., Ltd., and the works of Messrs. Blair & Co., Ltd. (marine engineers).

A LARGE AMERICAN WATER-POWER STATION

A DESCRIPTION of a large water power-station in Minnesota, on the St. Louis River, belonging to the Great Northern Power Co., is given in our American contemporary, *Power*. Fig. 1 gives a sketch map showing the way in which the hydraulic installation has been arranged. By means of a concrete dam 38 ft. in height and 1,000 ft. long, a storage reservoir has been formed about three-quarters of a square mile in area, at the south-east corner of which is another concrete dam with racks and head gates to admit water to a canal two miles long, 70 ft. wide, and 15 ft. deep, which ends in a forebay covering 40 acres. The service reservoir is 464 ft. above Lake Superior, and has a gross capacity on its 12 ft. of available draft of 130,000,000 cubic feet of water, which is amply sufficient to accomplish the purposes of conservation and regulation.

The service reservoir has an important function in clearing the water from needle ice. No anchor ice has ever been observed in the river. At the discharge of the service reservoir and forebay are curtain walls with submerged arches through which the water flows. These are of ample section to make the current passing through them quite slow. It is a fact that while the entire surface of the service reservoir may be covered with bark, chips, and other *débris* from saw and pulp mills above, the water coming out of these arches and flowing along the canal toward the power-station is perfectly clean, although the rack screens in the reservoir are coarse. Another series of curtain walls, submerged arches, and a finer rack will perform the same duty at the lower end of the forebay.

The canal into which water from the service reservoir passes is 8,500 ft. long, and has been excavated for its entire length in the slope of a hillside. At the foot of the forebay another concrete dam, with racks and head gates, has been erected, and

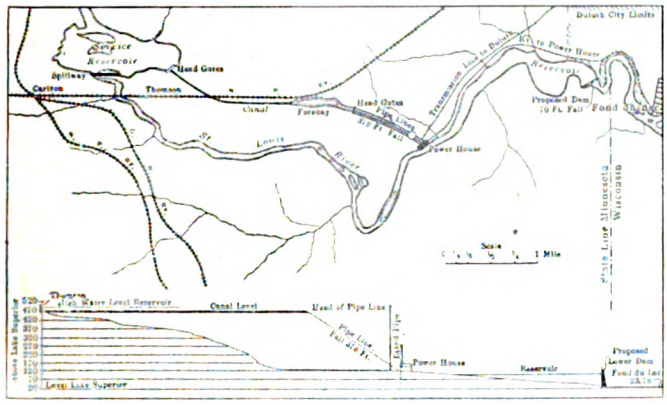

FIG. 1.—SKETCH PLAN OF SYSTEM.

from this start the 7-ft. penstocks, one of which has been installed for each water-wheel. This pipe line is 5,000 ft. long, the upper 4,000 ft. being of wooden stave construction, and the lower 1,000 ft. of riveted steel leading down over a steep bluff to the power-station on the river bank below, giving a working head of 378 ft. It will be noted that the three miles of canal and pipe line cut off five miles of the river, which here makes a curve.

The wood pipe is built of clear red-wood timber staves, tied by ¾-in. steel rods with malleable shoes and turn-buckles. Each wood pipe at its foot passes into a cast bell-shaped section of the steel line, where it is thoroughly calked with lead and oakum. There are similar sections at the upper ends of the wood pipes. The steel pipe is made of plates which are thoroughly riveted and were dipped into hot asphalt when laid. The entire line is laid in a covered trench, and at its lower end the pipe is anchored in concrete built up from bed-rock beneath the power-house. Under normal conditions the pipe lines deliver water at the rate of 335 cubic feet per second, which is equivalent to 10,000 horse-power. The friction loss is equivalent to about 10 ft. of head, and that in the canals when running full is about 6 ft. more.

At the top of the bluff above the power-house the pipe lines are connected to a cross receiver. From this rises a 6-ft. stand-pipe connecting with a tank 30 ft. in diameter and 52 ft. high, the top of which is 250 ft. above the foundation of the structure, and slightly above the level of the forebay. The stand-pipe is for the purpose of maintaining an even pressure in the pipe lines, and to prevent a surge due to sudden in-

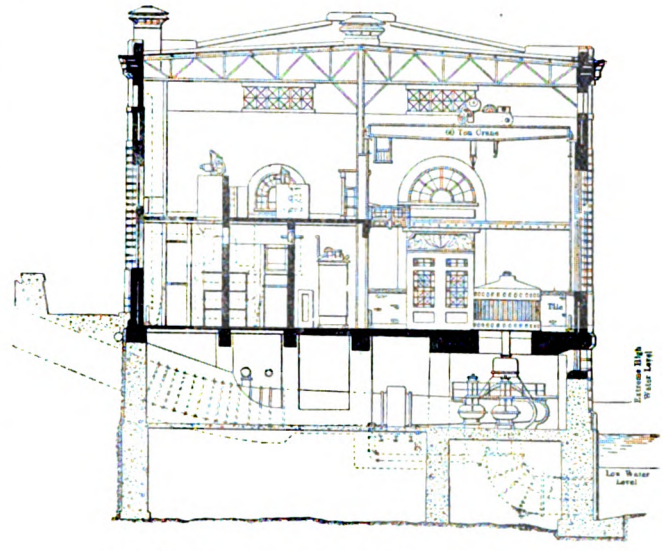

FIG. 2.—SECTIONAL ELEVATION OF POWER-HOUSE.

crease in load; the total quantity of water contained in the pipe, receiver, and tank will be 312,000 gallons, weighing 1,300 tons.

The water passes to the power-house, which is designed to accommodate four turbines. It is now 77×181 ft. in area, and when completed it will be 313 ft. long, and will contain eight generating units, each unit consisting of one 13,500-h.p. vertical reaction turbine of the Francis type built by Allis-Chalmers Co., with a 7,500-KW. vertical three-phase 6,600-volt 25-cycle generator, capable of developing 25 per cent. overload for three hours, and mounted upon the turbine shaft. The sets run at 375 r.p.m. It is claimed that these are the largest turbines of their class ever put into service. The runners are 62 in. in diameter, and run at a very high speed for their size.

A section of the station is given in Fig. 2, from which the relative positions of the turbines and alternators can be seen, and a plan is shown in Fig. 3. In each penstock a 66-inch hydraulically operated gate-valve is provided, and these are said to be the largest ever constructed for such pressures. Two 24-in. pressure regulators are placed on each penstock between the gate-valves and the turbines. These are arranged so that they can be operated automatically by a governor on the turbine, and they can also be set to open when the pressure in the penstock rises above a predetermined amount. Each regulator is fitted with a dash-pot having a time-element release that closes the valve gradually and automatically after the pressure

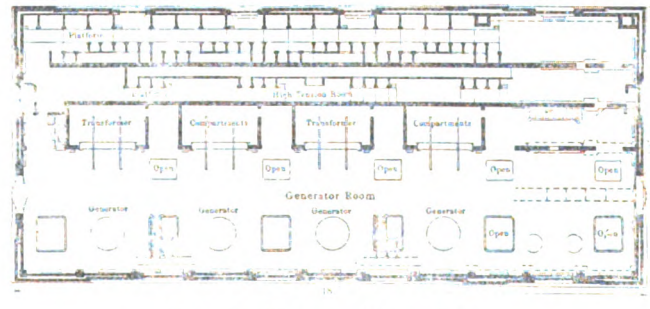

FIG. 3.—PLAN OF POWER-HOUSE.

is relieved, in order to reduce the waste of water. All these pressure regulators are operated in multiple through the cross receiver at the standpipe.

Digitized by Google

The quantity of water supplied to the turbines is controlled by the position of series of movable guide vanes or gates surrounding the runner in the turbine casing, and arranged so that they overlap and can be turned to close the opening between them. These vanes are actuated by a centrifugal governor through a system of cylinders worked partly by the water pressure and partly by a high pressure oil supply. The supply can also be controlled by hand.

The turbines are supplied with water from the penstocks through a ring system of 16-in. pipes. Each leg of the ring is connected with each penstock, and is fitted wit.. valves arranged so either wheel can be supplied from any penstock. The water is discharged from these wheels into the river through a pipe in the front wall of the building.

The alternators' rotors are coupled directly to the vertical turbine shafts, and the whole weight of the revolving parts is taken by a film of oil supplied to the thrust bearings under pressure of a special system of pumps.

Excitation for the main generators is furnished by two 250-kilowatt eight-pole 125-volt direct-current generators, each direct-connected to a vertical 500-h.p. impulse turbine built by the Allis-Chambers Co. Each of the generators has sufficient capacity to supply excitation current to all of the eight main units which the station will eventually contain.

The current generated is stepped up for transmission to the sub-station by single 7,500-kw. three-phase oil-insulated water-cooled transformers, which are 14·88 ft. high, 15 ft. long, and 5·88 ft. wide, and contain windings to transform the current to 30,000 or 60,000 volts, as desired. The core and windings weigh about 65 tons, and can be lifted bodily out of the casing. Surface condensers cool the oil, which is circulated by a special motor-pump set. The main switches are all of the motor-operated oil-break pattern arranged for distant control from a benchboard placed on a gallery that gives the operator an unobstructed view of the main units. All low-tension wiring is insulated and carried in conduits laid in the floors, while all high-tension wiring is bare and is hung on insulated supports in brick compartments. Throughout the scheme each set of unit wiring can be carried through any transformer and to any one of the transmission lines, and this plan will be continued as the number of units is increased to the maximum. For the control of the entire 80,000 horse-power there is a switchboard that is less than 19 ft. long, being unusually compact. In the centre of this board is the panel controlling all station lighting and power, and on each side are four panels, one for each of the eight units of the completed plant.

Power is carried to the centre of consumption over wires placed on steel towers, along a right-of-way 100 ft. wide, the property of the company. These towers are spaced from 300 to 1,000 ft. apart, and are from 40 to 60 ft. high, depending on the topography of the country. A voltage of 30,000 is carried on No. oo six-strand copper cables, and an overhead steel cable is carried on the towers as a lightning arrester, also a telephone line running into insulated booths along the high-tension lines.

The main sub-station is at Duluth, 14 miles away, and contains the necessary transformers and switching devices for distributing current at 13,200 volts to the various customers in Duluth and Superior. In this building are located two 1,500-kilowatt motor-generator sets for supplying 550-volt direct current to the street railway. Later, other sub-stations will be built at West Duluth and Superior, and provisions made for conveying current to the great iron mines of the Missabe and Vermilion iron ranges, situated at an average of about 70 miles from the power station.

Part of the 13,200-volt transmission system is underground. The company now has some 12 miles of cable skirting the harbour and railroad lines, as well as 16 miles of overhead circuits additional to the main feeders from the power-station. One of the cables is laid across the harbour to Superior, in a trench dredged 30 ft. below water line, or 8 ft. beneath the keel of the deepest-laden ship that can pass the Sault River.

ELECTRIC SIGNALLING IN AUSTRALIAN MINES

An article in the *Australian Mining Standard* gives some interesting information with respect to the systems of electrical mine signalling employed in the large mines of the Kalgoorlie district. The old mechanical knocker, with its accompanying and somewhat cumbersome system of levers, lines, and bell cranks is still to a large extent in use, but as time goes on, and the mines become deeper, so, no doubt, will the employment of this system become less.

There are two main systems of electrical signalling at present in use in the Kalgoorlie mines, viz., the trembling and the single-stroke bell systems, and, of course, there are several modifications of both. The Kalgoorlie gold mine employs the Siemens-Halske single-stroke bell system. These bells have a 14-inch gong, and each takes 1 ampere at a pressure of 110 volts. The current is generated by a small independent direct-current Ganz dynamo driven by a 2-h.p. three-phase motor, which receives its current from the alternating current power mains. As a standby in case of accident happening to the dynamo, there are installed 140 auxiliary Leclanche cells of large size, each having an output of about one ampere at 1·5 volts. This reserve battery is sufficient to run the entire signalling system for a period of eight hours. A special armoured cable, containing eight well-insulated wires, is used in the shaft, the wires being so well protected as to be quite immune from the effects of water or of shocks caused by blasting.

A cheaper but rather unsatisfactory method of protecting the wires in use on some mines is that of placing them in ordinary gas piping, secured to the side of the shaft with staples. This piping is connected at each level to water-tight junction boxes by means of a gland and stuffing box, and it is in these junction boxes that trouble is likely to occur. The water in the Kalgoorlie mines is notoriously heavily mineralised, and if any of this, or even the slightest dampness caused by this saline solution, finds its way into the junction boxes, severe electrolytic action is set up, and trouble follows. The necessity, therefore, of having these boxes absolutely damp-proof is apparent.

Returning to the Kalgoorlie gold mine system, it may be mentioned that two pairs of wires branch off from the junction box on each level. Each pair is connected to a bell and a sliding-contact-type press. There is at present no intercommunication between the levels, and consequently, if one level wishes to communicate with another, the signal has to be transmitted to the driver, who then retransmits it to the particular level desired. It is intended later on, however, to put in the necessary connections for intercommunication between the levels. Five levels only can be connected with the system by means of an 8-wire cable. One wire is used as a return, and is common to all levels. There are five wires for the five levels, each level having its independent circuit. The other two wires are in circuit with the engine-driver's bell and the presses in the levels. The driver has before him a sliding contact level indicator, which enables him to throw into circuit any level to which he desires to signal. He has also an indicator exhibiting the number of knocks rung, thus doing away with the possibility of mistaking a signal. When it is desired at any time to extend the system to more levels, another cable will have to be put down in addition to the one now in use, as already all of the eight wires in the present cable are employed.

With the system in use on the Great Boulder mine, polarised bells are employed, which are rung with a 15-volt alternating current transformed down from a 550-volt pressure in the mines. The principal objection, however, to the use of an alternating current for working mine signals appears to be the extreme electrolytic action that such a current induces in the connections, it being far more active in this respect than a continuous current.

Telephones are useful as an adjunct to a signalling system, but their employment in West Australian mines is very limited, as it is not always considered advisable, for various reasons, to place the men underground in too intimate communication with the surface.

An India-rubber Exhibition.—An International Exhibition of the Rubber and Allied Trades will be held at Olympia, from September 14th to 26th. Exhibits will show how rubber trees grow and are tapped, and the various processes in the manufacture of the material. We are informed that exhibits are being received from a number of Continental countries, as well as from the United Kingdom, and also from the various rubber-growing countries, which will be officially represented. "Living pictures" on the manufacture of rubber in England and America, &c., will be shown. Gutta-percha will not be excluded, and growing gutta-percha trees will be exhibited, and also the treatment of this material. A large number of manufacturers are, of course, also represented. Mr. H. C. Pearson, the editor of the *India-rubber World* of New York, will give lectures on various subjects connected with the manufacture of rubber goods, crude rubber production, and on synthetic rubbers on certain days during the fortnight.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Aug. 20th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

9,950. **Variable Frequency, Constant Speed Polyphase Alternators for Marine Propulsion.** H. A. Mavor and Mavor & Coulson, Ltd. In systems of electrical marine propulsion in which turbo-alternators drive polyphase motors directly coupled to the propeller shafts, the speed variation of the motors is best obtained by varying the periodicity of the generated alternating current. The object of the present invention is to provide means whereby the turbo-generator set may be capable of generating an alternating current of variable periodicity, although the steam turbine runs at a constant speed. One method of doing this is to mount the secondary element of the alternator so that it can revolve concentrically around the primary element (the rotor field system), which is directly coupled to the steam turbine. The periodicity of the generated current can then be decreased or increased by revolving the secondary element in the same or opposite direction respectively to that of the primary element or usual rotor. The secondary element may be revolved by gearing operated from the rotor shaft, or by means of an electric motor. The starting of the main motors may be effected by gradually raising the periodicity from zero. Other similar methods of producing a variable frequency with constant turbine speed are described in the specification. Eight claims, three figures.

28,494. **Protective Device for Transmission Lines.** British Thomson-Houston Co. (*General Electric Co., U.S.A.*). A spark-gap protective device, provided with means for maintaining a flow of insulating fluid along the electrodes and across the gaps. The rate of flow of the fluid is caused to be greater than the velocity with which the vapour from the electrodes moves across the gaps. This allows the system to be relieved of any excessive charge, but prevents the formation of arcs across the gaps. If the electrodes are made of platinum the vapour will move across the gap at the rate of 1,400 ft. per second, in which case the insulating fluid would be forced across the gap at a velocity of about 2,000 ft. per second. The fluid between the electrodes, which has been ionised by the discharge, is continually swept away and replaced by fresh, cool insulating fluid, so that the discharge ceases directly the voltage of the system becomes normal. A small compressor pumps the insulating fluid at the necessary pressure through a pipe with branches to all the spark gaps. Three claims, one figure.

28,494. **Prevention of Falling of Tramway Trolley Wires.** A. G. Boon and F. Mellaerts. In overhead tramway fittings, such as points or section insulators, the conductor always vibrates most at the point where it is joined to the fitting, as the latter is more rigid than the conductor itself. It is at this point that most breakages occur. According to the present invention a joint is provided on each side of the fitting, consisting of a sleeve of rivetted sheet-iron enclosing the conductor. A wedge with saw-like teeth prevents the conductor from slipping in the sleeve. A steel wire attached to the sleeve, and also to the fitting, prevents the conductor from falling in case of breakage. One claim, three figures.

1908 Patent

3,096. **Speed Control of Single-Phase Commutator Motors.** British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*). In the driving of machine tools, such as planing machines, it is desirable to have one speed for the working stroke, and another for the return or idle stroke. The working speed should be independent of the load, and the return speed greater than the working speed. According to this invention, when a single-phase commutator motor is employed for such work, the motor is given a shunt characteristic during the working period, while during the return or idle period it runs with a series characteristic. The change over from one characteristic to the other is obtained by operating a two-way switch connecting one of the exciting brushes to a fixed point on the stator winding, or one of the short-circuiting brushes respectively. This switching operation may be performed automatically by the machine tool. To prevent the tool from entering the work at too great a speed the change over may be performed before the end of the idle stroke is reached. Three claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

17,458, Hickley. Electrolytic current rectifiers.
17,526, Trainor. Electrically-propelled vehicles and boats.
17,661, Dowsing. Electric switch for series lighting.
17,683, Lake (*Newhall*). Supports for telephone and telegraph wires.
17,718, Deutsche Beck Bogenlampen Ges. Arc lamps.
18,053, Jahoda, Von Loti, Von Loti, & Latzko. Manufacture of filaments for electric lamps.
19,157, Imray (*Glühlumpen-Fabrik "Union" Ges.*). Manufacture of filaments for electric lamps.
20,110, Kelman. Switch and circuit breakers for high potential circuits.
21,475, Basset. Electric battery.
21,904, Eckstein, Heap & Mellis. Automatic circuit breakers
22,457, Duncan. Electrically connecting dynamo - electric machines with their supply circuits.
27,289, Galletti. Methods of producing electric oscillations.
27,569, Johnson (Firm of *W. C. Heraeus*). Electric resistance thermometers.
27,825, Felten & Guilleaume Lahmeyerwerke Akt.-Ges. Electrical igniters for internal-combustion engines.

1908 Patents

899, Siemens Schuckertwerke Ges. Electric cable boxes or troughs.
1,705, Schanschieff. Sparking-plugs
1,773, Alexanderson. Electric motor control.
3,231, Iversen. Device for regulating power supply in hoisting plants.
4,257, Firm Robert Bosch. Electrical ignition devices for internal-combustion engines.
4,762, Allgemeine Elektricitäts-Ges. Electrodes for arc lamps.
6,105, Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*). Means for ozonising air.
7,006, Porsche. Electric power transmission for motor vehicles.
7,231, Brush Electrical Engineering Co. & Acland. Tramway trucks.
7,401, Otis Elevator Co. (*Otis Elevator Co.*). Safety apparatus for lifts.
8,415, Noeggerath. Dynamo-electric machines.
8,996, Soc. Anon. L'Electricité Moderne. Apparatus for storing the heat furnished by a source of electricity.
9,092, Mason. Sparking or ignition plugs.
9,235, Allgemeine Elektricitäts-Ges. Process for extracting nitrogen peroxide from nitric oxide air mixtures.
10,023, Eisenstein. Condensers of the "Leyden jar" type.
13,489, Kuhlo. Metal armouring for electric conductors.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1907 Patent

19,672, Ges. für Verwertung Chemischer Produkte Ges. Metal filaments for electric lamps.

1908 Patents

7,328, Allgemeine Elektricitäts-Ges. Arc lamps.
11,710, Siemens & Halske Akt.-Ges. Manufacture of a plastic mass from tungsten compounds.
12,876, Siemens-Schuckertwerke Ges. Device for starting combustion motors.
16,096, Siemens & Halske Akt.-Ges. Telephone installations.
16,272, Belin. Apparatus for reproducing at a distance pictures or designs.
16,296, Müller. Miners' safety lamps.
16,446, Siemens & Halske Akt.-Ges. Telegraph apparatus applicable to fire-alarms.

Expiring Patents

No patents of electrical interest expire during the current week.

LOCAL NOTES

ABERDEEN: *Proposed Electrobus Service.*—At a meeting of the Town Council last week, a letter was read from the London Electrobus Co., intimating that they propose to apply for a licence for opening in the City of Aberdeen a service of electric omnibuses on certain routes where the city is not served by electric tramways.

ABRAM: *The Maypole Colliery*—Messrs. Pearson & Knowles Coal & Iron Co., Ltd., of Warrington, were putting down powerful electrical plant at their Maypole Collieries, Abram, near Wigan, at a cost of between £30,000 and £40,000; but it is feared that the work will be somewhat interfered with owing to the disastrous explosion there on the 18th inst., and the subsequent flooding of the mine. We understand, however, that the generating station which was being built near the No. 2 pit escaped damage.

AUSTRALIA: *Victoria: Malvern-Prahran Electric Tramways.*—According to the *Australian Mining Standard*, the Victorian Executive Council has empowered the municipalities of Malvern and Prahran to proceed with the construction of an electric tramway connecting the two places. The first portion of the new line must be completed and ready for opening within two years, and other portions within ten years of the date of payment of a sum of £13,000 to the Railway Commissioners in respect of the necessary regrading work. The speed of cars equipped with hand-brakes is to be limited to fifteen miles an hour, but in cases of cars with approved power brakes the limit is extended to 20 miles an hour.

BARGOED: *Telephone Service.*—At the Bargoed Chamber of Commerce on Tuesday, a letter was read from the Postmaster-General, stating that instructions had been given for extensions of the telephone system to the Post Office in Hanbury Road. It is reported that efforts are being made to obtain a trunk line direct between Bargoed and Cardiff.

BELTURBET: *Electric Lighting Scheme.*—It has been decided to accept the offer of a firm of electrical engineers and contractors of Dublin to submit a detailed report, free of expense to the Council, on a scheme for electric lighting of the town.

BRAZIL: *Electric Lighting.*—A British Consular report on the district of Santos remarks that the town of Curityba is lighted by electricity supplied by a German company. This company has been doing well for several years, and in 1907 obtained a further concession to exploit the Cayacanga waterfall on the Yguassú River for the production of electric power. The towns of Paranagua, Antonina, and Ponta Grossa also possess electric light machinery, all being bought through German firms.

CHILE: *Large Water-power Scheme.*—According to an American Consular report, the Empresa de Tracción y Alumbrado Electricos, of Santiago, is installing a 22,000-h.p. hydraulic electric power plant at La Florida, whence the current is to be transmitted to the city over an underground cable at a tension of 12,000 volts.

DARTFORD: *Street Lighting.*—At the last meeting of the U.D.C., Mr. Wooller moved that the General Purposes Committee be instructed to go into the matter of street lighting, and bring up a scheme for the reduction of the yearly expenditure of £1,868, or about £5 per electric lamp. In 1905 the price was £1,360, and in 1906 it was £1,586, while last year it rose to £1,868. He did not want to do the undertaking any harm, but he was quite sure the Council would never pay such prices to a contractor. Then, again, there was 120 gas lamps at £4 5s. each, while Crayford was only paying £3 3s. 10d. In reply to a question, the electrical engineer said he did not agree with the statement that the electric lamps cost £5 per annum each, and Mr. Putland pointed out that of the £1,868, between £250 and £300 was for lamp columns, &c. The resolution in the result was negatived.

DUBLIN: *Proposed extension.*—A report has been submitted by the Lighting Committee on the capital expenditure on the city electrical undertaking, and considering in some detail the various applications for extension of mains which have been received from different districts. Considerable extensions are recommended, and recommendations are made to apply for a loan to cover the following items:—Extension of mains of Blackpits district, £9,600; extension around Ringsend Dock, £10,500; completion of Drumcondra extension, £9,000; deficit on loans in connection with Mr. Hammond's scheme, £10,925; extension in streets not in original area of supply already carried out, £3,000; extension of distributors to be made as required, £5,000; services and meters, £5,000. The improvement of street lighting is also dealt with, and it is stated that the cost of lighting and maintaining 100 c.p. metal filament lamps on routes where mains are already laid would be £4 each. The proposed extensions in this direction are put at £3,500, bringing the total loan recommended up to £69,705. The report was discussed at a meeting of the Corporation last Friday, one member stating that the electric lighting earnings only produced 3 per cent. on the capital outlay. Another member said that that was due to the enormous expense incurred by the provision of electric lighting for Clontarf and Kilmainham districts, which they might ask Parliament ultimately to cut off from the city. Finally, it was resolved to ask for a joint report from the Lighting and Finance Committees.

DUNFERMLINE: *Electricity Supply.*—The Town Council have finally approved the agreement with the Fife Electric Power Co., whereby the Provisional Order for lighting is handed over to the company, who undertake to work the Order for a period of thirty years, at the expiry of which the Corporation on certain payments may re-acquire the Order and obtain the customers got by the company during the currency of the agreement. The company further agree to pay "all proper expenses" incurred by the Corporation in securing the Order.

EALING: *Col. Yorke's Inspection.*—In reply to the protest of the Mayor of Ealing that Col. Yorke's recent inspection of the tramway track was insufficient, the Board of Trade has promised that full consideration shall be given to the matter (see ELECTRICAL ENGINEERING, August 20th, page 274). A movement is on foot against the retention of the present centre standards in some parts of the borough, which are considered to be a danger to traffic.

ESSEX: *Light Railway Order.*—The Board of Trade have recently confirmed the undermentioned Order, made by the Light Railway Commissioners:—Central Essex Light Railway (Amendment and Extension of Time) Order, 1908, amending the Central Essex Light Railway Orders, 1901 to 1907.

FINCHLEY: *Accident Attributed to Centre Tramway Poles.*—A fatal accident attributed to the presence of tramway poles in the centre of the road is reported from Finchley. It appears that a pony, drawing a light trap, took fright at a steam roller coming in the opposite direction, and collided with a centre tramway pole, with the result that the driver of the trap was thrown out in front of the steam roller, by which he was run over.

GREENOCK: *Electricity Accounts.*—The report and accounts show an increase of 41 per cent. in the units supplied to private consumers, and the income from private lighting has risen from £13,011 to £16,874. After a contribution of £4,705 to the sinking fund and of £465 to the depreciation fund for free wiring and hired motors, and paying interest amounting to £3,415, the year's working shows a net surplus of £384 to be added to the balance of £266 carried over from the previous year.

HASLINGDEN: *Tramways.*—The Town Clerk has been instructed to apply to the Board of Trade for a renewal of the license to use steam on the tramways within the borough for the time being, the present license expiring on September 7th.

KINGSTON-ON-THAMES: *Extensions and Street Lighting.*—A Local Government Board inquiry was held last week with reference to an application by the Town Council to borrow £12,600 for the electricity undertaking. Amongst the items making up the total were the following:—£1,150, engine-room works; £2,898, mains; £2,850, services; £1,890, transformer kiosks; £340, transformer sub-stations; £600, high- and low-tension disconnecting pillars; £300, arc lighting; £264, incandescent lighting. Mr. J. E. Edgcome, electrical engineer, said there were 100 incandescent street lamps now installed, and it was proposed to install an additional 200. The annual cost of the gas incandescent street lamps was £3 8s. 6d., including painting, and the Council credited the undertaking with a similar sum for each incandescent electric lamp, which price, he believed, covered the cost as it worked out at 2d. per unit. The arc lamps were charged £20 per annum each. In the course of the inquiry it was stated that there was a deficiency last year of £884. The undertaking was established in 1894, and the deficit up to the present, £10,739. In reply to the Inspector, Mr. Edgcome said the present loss was due primarily to the great increase of the price of coal, and also to reductions in the charges for current.—The Inspector: Were you justified in making the reductions?—Mr. Edgcome: We could get nobody to take current for power at 3d., and I think we have justified the 1½d. price by the increased day load.—The Town Clerk: The number of consumers for power and heating has increased from 66 to 104 in a single year.—The Inspector: You have more consumers, but is it paying you?—Mr. Edgcome said that with coal at the price it was last year the charges were not paying, but at the present time the charges just about paid. A ratepayer who was present said it was clear to him that the present generation could not hope to get any relief from the burden which the undertaking imposed on the rates. Alderman Clarke urged the Inspector to do what he could to allow the whole of the labour of the contemplated works to be charged to capital account, and so relieve the present ratepayers. At the close of a long inquiry, the Inspector visited the works.

LA PLATA: *Electric Railway.*—The *Review of the River Plate* reports that the Pacific Railway Co. have acquired the

Digitized by Google

concession granted to Sr. O. Franke for an electric railway between Retiro and La Plata.

LINCOLN: *Proposed Inclined Railway.*—A proposal has been made to construct an electric railway up the steep hill in Lincoln on which the cathedral stands. The line would have a total length of 1,000 ft. and a rise of 142 ft. A part of the route would be in tunnel. Alternative schemes are being considered for the rack and wire rope systems. It is stated that the originator of the scheme, Mr. W. R. Lilly, Sheriff of Lincoln, has been for the last 20 years acquiring property on the route with a view to selling it at cost price to the Corporation. The lower terminus is to be at the corner of St. Martin's Old Churchyard, and the upper terminus in Exchequer Gate.

LONDON: *L.C.C. Tramways.*—According to the *Times*, all difficulties in the way of the electrification of the remaining horsed tramways in Battersea and Wandsworth have been practically removed. In regard to the Queen's Road and Chelsea Bridge Road, a financial agreement has been come to, and the work will be proceeded with at once. As to the line from St. John's Hill to Vauxhall, a tentative agreement has also been arrived at, subject to confirmation by the Borough Council at its meeting in September and the L.C.C. when it resumes. It is expected that this will be accorded, and the work will then be put in hand. Both lines will be on the conduit system, but in Queen's Road, owing to the very low railway bridges, only single-deck cars can be used.

Hammersmith: The Workhouse Lighting.—It is reported that three of the Poor Law guardians have been surcharged by the Local Government Board auditor a sum of £93 16s. 3d. in connection with the electric light installation at the new workhouse.

Paddington.—In his annual report, the Medical Officer of Health (Dr. R. Dudfield) says that the removal of the Great Western Co.'s generating station from the borough has, to some extent, brought about diminution in the amount of "black smoke."

LYONS: *Proposed Automatic Telephone Exchange.*—It is announced that an automatic telephone exchange is being established in Lyons, and will be in working order by September 5th. Two hundred selected subscribers are to be connected up at first, and experiments with public call-boxes are also to be tried.

MELBOURNE: *Electricity Accounts.*—The annual report states that the units sold during the year were 6,796,180, and the gross revenue was £92,364. The working expenses amounted to £42,765, and of the balance, £16,144 was absorbed by interest and £4,400 by sinking fund, and £20,858 was carried to depreciation account. The total capital expenditure on the undertaking has been £424,273.

MEXBOROUGH: *Electricity Accounts.*—The net revenue for the past year has amounted to £1,894, as against £1,981 for the previous year, and the net profit for the year has been £427, which is considered satisfactory for an undertaking only four years old in a town of not more than 13,000 inhabitants.

NEWPORT (Mon.): *Tramway Accident.*—A collision occurred between an electric tramcar and two runaway railway waggons at a level crossing near the G.W.R. locomotive yard. Several persons were injured, but not seriously.

PORTPATRICK: *Fire at Electricity Works.*—A fire occurred last week at the generating station at Craigoch Dam, belonging to the Portpatrick Electric Supply Co. It contained an oil engine set, as well as a water power plant, and considerable damage was done. It is reported that within forty-eight hours of the fire Messrs Lowden Bros., electrical engineers, of Dundee, had set up an engine and dynamo near the distributing station in the town, and that since then the supply to the town has been maintained from this plant in a satisfactory manner.

RUSSIA: *Electric Furnaces in Steel Works.*—An American Consular report states that the Magnesite Co., owners of the ironworks on the River Ural, have decided to build a new factory equipped with electric furnaces for dealing with chromium iron ores. The new works will be on the River Satka, about 20 miles from the present works, and current will be obtained from the water power station in the district.

SHEFFIELD: *Automatic Tramway Point Controllers.*—The number of automatic point controllers on the tramway system has gradually increased from one to nine, and two further controllers are to be installed. It is said that each apparatus, which costs about £100, effects a saving of £120 to £140 per annum in wages of pointsmen.

SOUTHEND: *Power Rates.*—An application from a laundry company, stating that they were prepared to take power if the Corporation would agree to a charge of 1d. per unit between 6 a.m. and 6 p.m., was discussed last week by the Council. The electrical engineer, however, recommended the following charge from April to September, inclusive—6 a.m. to 7 p.m. (day), 1½d. per unit: 7 p.m. to 6 a.m. (night), 6d. per unit. From October to March, inclusive—6 a.m. to 6 p.m. (day), 1½d. per unit; 6 p.m. to 6 a.m. (night), 6d. per unit. After some discussion the recommendation was adopted.

STRICHEN (ABERDEEN): *Street Lighting.*—Some estimates have been put before a local sub-committee regarding the comparative cost of gas and electric street lighting. It is assumed that a complete plant, comprising oil engine dynamo, 30 lamps of 30 c.p., with overhead wires on poles, would cost £250, and that the annual interest on the capital would be £10. The actual cost of the power for the 30 lamps for 500 hours is put at £6 5s., and a remaining £4 per annum for attendance and cleaning brings the total up to £20 5s. This would show a saving on the £21 14s. 2d. paid for gas lighting last year. The scheme is to be considered at a meeting on next Wednesday.

THETFORD (NORFOLK).—According to the *Daily Mail*, owing to a quarrel with the local gas company, the supply has been cut off and the market-place is lighted by Chinese lanterns.

TURKEY: *Electrical Imports.*—The Board of Trade Journal announces that the prohibition of the importation into Turkey of electrical instruments has been withdrawn. With the improved state of affairs considerable electrical engineering developments may be expected. It is reported that three concessions have been granted for electric lighting and the construction of tramways in Constantinople and its suburbs, and that the Kaifa Dera section of the Hadja railway is also to be worked by electricity.

WORKINGTON: *Revocation of Order.*—The Board of Trade give notice that they have revoked the Workington Electric Lighting Order, 1901, as confirmed by the Electric Lighting Orders Confirmation (No. 5) Act, 1901, as to the whole of the area of supply, as from the 14th day of August, 1908.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA (VICTORIA).—The lighting of the townships of Terang and Camperdown by electricity, has been decided upon, and tenders will shortly be required for the installation.

BELGIUM.—The *Bulletin Commercial* (Brussels) announces that tenders will be opened at 11 a.m. on September 2nd, at the office of the Société Nationale des Chemins de Fer Vicinaux, Rue de la Science 14, Brussels, for the supply of electric cables and the laying of conduits required for the Brussels-Grimberghen section of the local line from Brussels to Humbeek. Tenders must be enclosed in registered envelopes addressed to the Director-General of the Société, and must reach the above address not later than the day preceding that appointed for the adjudication. Plans and specifications (*cahiers des charges*) may be consulted at the same address, or may be obtained at the "Bureau des Adjudications (Musée Commercial)," rue des Augustins, 15, Brussels. The price of the specification is 1 franc per copy, and of the plans, 16 francs.

BLACKBURN.—The Electricity Committee invite tenders for the supply of steam coal for the nine months ending June 30th, 1909. Tenders close on August 24th.

FROME.—Application is being made to the Local Government Board for a loan of £11,000 to carry out extensions to the electricity undertaking.

HASLINGDEN.—It has been decided to apply to the Board of Trade for sanction for a loan of £7,200 for the purpose of providing the necessary machinery, &c., required to provide electrical power to work the tramways in this borough.

KINGSTON.—The proposed loan of £12,600, into which Mr. H. Shelford Bidwell made a Local Government Board inquiry last week, is to include the following items:—£1,089 for excess capital expenditure already incurred; work at the engine-room, £1,150; mains, £2,898; services (including mains, fuse-boxes, &c.), £2,850; transformer kiosks, £1,890; extra transformers, £340; high- and low-tension disconnecting pillars, £600; arc lighting, £300; incandescent electric lighting, £264; converting 160 gas lamps as above, £928; cost of application, law charges, plans, &c., £250 10s. 8d.

MANSFIELD.—Application is to be made to the Local Government Board for sanction to the following loans:—£2,500, repayable in 30 years, for electricity mains; £500 for electricity meters.

PERTH.—Tenders are invited for the electric lighting and power installation in connection with the erection of the new City Hall. Particulars from Mr. H. E. Clifford, 225 St. Vincent Street, Glasgow (deposit 10s. 6d., returnable). Tenders by Saturday, August 29th, to the Town Clerk.

SALFORD.—The Electricity Committee invite tenders for the supply and delivery of lighting and power feeder and distributor pillars. Specification and form of tender may be obtained on application at the office of Mr. Victor A. H. M'Cowen, Borough Electrical Engineer, Frederick Road, Pendleton. Tenders to be sent to the Chairman of the Electricity Committee by noon, Monday, September 14th, 1908.

Digitized by Google

STIRLING.—Application is to be made to the Secretary for Scotland for powers for a loan of £3,000 for new feeder cables.

WHITEHAVEN.—With reference to the application which has been made to the Local Government Board for a loan of £1,700 for the following purposes, condensing plant £1,200, battery switchboard and boosters £300, main extensions and auxiliary plant £200, the committee have been advised that the last-mentioned sum is insufficient for the purpose, and it is now proposed to increase this item to £500, and apply to the Local Government Board for leave to increase the amount of the loan for which sanction is asked from £1,700 to £2,000.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Alterations to Gracechurch Buildings, Gracechurch Street, E.C. Builders, Halliday & Greenwood, 144a Loughboro' Park, Brixton, S.W.

N.E.—Installation of electricity (light and power), telephones, &c., in additions to Homerton Infirmary. F. B. Coles, Clerk to the Guardians, Sidney Road, Homerton, N.E.

N.W.—Rebuilding piano factory for Moningham & Weston, Bayham Place, Camden Town, N.W.

W.—Extension National Gallery, Trafalgar Square (£15,979). Builders, F. and H. F. Higgs, Hinton Road, Loughboro' Junction, S.W.

Rebuilding 144 and 146 Great Portland Street. Builder, D. Prosser, 23-25 Charlotte Street, Fitzroy Square, W.

Alterations to drapery premises of Stagg & Mantle, Leicester Square. Builders, Hall, Beddall & Co., Waterloo Bridge, S.E.

Rebuilding business premises, 65 Wigmore Street. Builders, T. H. Kingerlee & Sons, Oxford, and Shepherd's Bush.

Rebuilding business premises in James Street. Builders, Meech & Goodall, Streatham Hill, S.W.

PROVINCES.

BARNET.—Rebuilding three shops and one house in High Street (destroyed by fire), for Harbord & Co. W. J. Wells, Peake & Baughen.

BARNSTAPLE.—Secondary school (to be commenced in February). S. W. F. Brown and G. W. P. Brown, Secretaries.

Garage, Old Red Lion Hotel.

Wesleyan School. Architect, W. A. Quarmby, Imperial Chambers, Grimshaw Street, Burnley.

BIRMINGHAM.—New gymnasium and club, Haden Street, for the Pelican Buildings, Ltd.

BRISTOL.—Police station and fire station (£3,028) and police station (£690). T. H. Tabbicom, City Engineer and Surveyor, Town Hall.

BURNLEY.—Six houses. Builders, Smith Bros., Ltd., Eastham Place, Turfmoor, Burnley.

CARDIFF.—Additions, &c., steam laundry. Architect, Henry Budgen, 95 St. Mary Street, Cardiff.

CARLISLE.—Turkish baths. H. C. Marks, City Engineer and Surveyor, 36 Fisher Street, Carlisle.

CATERHAM HILL.—Additions to school (£2,994). Architects, Jarvis & Richards, 10 Queen Anne's Gate, Westminster, S.W.

CHATHAM.—School (£10,250). Architect, Kent County Council.

CHICHESTER.—The engineer of the Electric Light Co. has been asked to prepare a report as to the cost of wiring the workhouse for electric light.

CLEETHORPES.—Twenty-nine houses and shop. Builder, J. Nutley, Mill Place, Cleethorpes, Great Grimsby.

CORK.—New technical schools. Architect, Arthur Hill, 22 Georges Street, Cork.

DARTFORD.—Extension of chemical department at Wellcome Chemical Works, for Burroughs, Wellcome & Co., Snow Hill Buildings, E.C.

DARWEN.—The Education Committee have decided to proceed with the erection of a new school at Ellison Fold. This will be followed by a new school in Cyprus Street.

DUDLEY.—Workhouse extension. Architect, C. E. Bateman, 81a and 83 Edmund Street, Birmingham.

DUNDEE.—Electrical engineering laboratory at University College. Architects, Mills & Shepherd, Clydesdale Bank Chambers, Dundee.

GREAT YARMOUTH.—Additions to premises, Primitive Methodist Church, Welholme Road.

HAMPSHIRE.—Proposed new asylum. H. Barber, Clerk to County Council, Winchester.

HARROGATE.—Extension of baths (£14,000). E. Bagshaw, Surveyor to the Corporation.

HASTINGS.—Nurses' home at workhouse infirmary. Architects, A. W. Jeffrey and Son, 5 Havelock Road, Hastings.

HINCKLEY.—New infirmary, and laundry block and alterations to workhouse. Architect, W. T. Grewcock, 8 New Street, Leicester.

HOYLAKE (CHESHIRE).—School (300 places). Architect, E. Ware, 45 Imperial Buildings, 20 Exchange Street, East Liverpool.

HUDDERSFIELD.—Warehouse. Architect, J. Berry, 3 Market Place, Huddersfield.

IPSWICH.—New offices, Queen Street, for Prudential Assurance Co., Holborn Bars, E.C.

LINCOLN.—Shops, Silver Street, for Lincoln Co-operative Society.

Additions to offices for Rusten, Proctor & Co., Anchor Street.

New showroom for Laurence & Son, High Street.

MAIDSTONE.—School (1,000 places). T. F. Bunting, Borough Surveyor.

MANCHESTER.—Jewish Hospital, Elizabeth Street and Sherborne Street, Cheetham.

Addition to St. Mary's School, Upper Mass Lane, Hulme.

Addition to Women's Home, Egerton Road, Rusholme.

NEWPORT (MON.).—New building and alterations to existing premises for Y.M.C.A. Architects, C. E. Compton & Habershon, Fawckner & Co., High Street, Newport.

OXFORD.—New Church of St. Stephen. Architect, A. M. Mowbray, 117 St. Aldate's Street, Oxford.

PENDLETON.—New Baptist church (£4,000). Architects, Cook & Son, 39, 44, and 44A Victoria Buildings, Victoria Street, Manchester.

ROTHERHAM.—Shops and houses, Masborough Equitable Pioneers' Society, Ltd.

Eight houses. Builder, T. Green, 46 Greaseborough Road, Rotherham.

SLIGO & LEITRIM.—Tenders are invited for the lighting of the Sligo & Leitrim District Lunatic Asylum with electricity or "petrol gas." Approximate number of lights, 450. Particulars from Anthony Scott & Son, architects, 49 Upper Sackville Street, Dublin. Tenders by September 15th.

STANNINGLEY.—A Methodist Chapel in Richardson Lane is to be lighted electrically, and if the installation proves satisfactory it is to be extended to the new Sunday School.

ST. ANNE'S-ON-THE-SEA.—Villa. Architect, J. D. Harker, St. Anne's-on-the-Sea.

Extension of Roman Catholic school; four houses; pair of villas. Architect, A. England, Carlton Chambers, St. Anne's-on-the-Sea.

SHEERNESS.—New Masonic hall. Architect, E. J. Hammond, 21 Balmoral Road, Gillingham.

SOUTHAMPTON.—Australian Emigration Offices (£5,000). Architect, Guy Prendergast, Scholing, Southampton.

STOCKPORT.—Carnegie Library (£10,000). R. Hyde, Town Clerk.

SUNDERLAND.—Stone buildings. Architect, J. W. Moncur, Town Hall, Fawcett Street, Sunderland.

Branch library. Architect, Hugh Hedley, 40 West Sunniside, Sunderland.

Warehouse, &c. Architects, W. & T. R. Milburn, 20 Fawcett Street, Sunderland.

Extension of ropery. Architects, W. & T. R. Milburn.

WESTON-SUPER-MARE.—Baptist Church, Clarence Park (£6,000).

WOKING.—School at Goldsworth. Education Architect, County Hall, Kingston-on-Thames.

Miscellaneous

ARGENTINE.—Several new telegraph lines are to be built in the Province of Salta, at a cost of $150,000 paper.

DUBLIN.—Tenders are invited for the supply of 500 single-phase meters and 100 three-phase meters. Particulars from City Electrical Engineer, Fleet Street, Dublin (fee £1, returnable). Tenders to the Chairman, Lighting Committee, 3 Cork Hill, Dublin, by Friday, September 4th.

HACKNEY.—Tenders are invited for the provision of electric light and power fittings, and electric-bells and telephone installations, at the extensions, now in the course of erection, of the infirmary at Homerton. Particulars from Mr. F. R. Coles, Clerk to the Guardians, Sydney Road, Homerton, and tenders by Monday, August 31st.

LAURENCO MARQUEZ (S.E. AFRICA).—An American Consular report states that tenders to supply electric cranes for the Gorjao Wharf at that port can be submitted for some months to come before the final adjudication is made.

MERTHYR TYDFIL.—Hills' Plymouth Co., Merthyr Tydfil, invite tenders for stores, including electrical appliances for the twelve months ending September 30th, 1909. Forms of tender may be obtained upon application in writing, enclosing stamped addressed foolscap envelope, and must be sent in not later than September 21st.

SOUTH AUSTRALIA.—Tenders are required by October 21st, for power plant for charging accumulators for telegraph purposes at the General P.O., Adelaide.

Digitized by Google

TASMANIA.—Tenders are required by the Postmaster-General's Department by November 2nd for material for accumulator equipment for telegraph purposes.

WESTERN AUSTRALIA.—Tenders are required by October 6th for the supply of telegraph and telephone material. Tenderers must state the country in which the articles tendered for have been made or produced, and in the case of manufactured articles where the material has been made or produced. Tenders must include Customs duty, if any. Copies of specifications, general conditions, and schedules of tender may be obtained at the General Post Office, Perth (where sealed patterns can be seen), and at the General Post Offices, Adelaide, Melbourne, Sydney, Brisbane, Hobart, and the Commonwealth Office, London.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—Nine tenders, varying in value from £58,240 to £43,641, have been received for the construction of a complete central battery switchboard for the new telephone exchange at Melbourne, and the tender of the Western Electric Co. at the latter figure has been accepted. It is stated that 93 per cent. of the work will be of British origin, and the remaining 7 per cent. by the Belgium and American manufacturers.

BAHAMAS.—The tender of Messrs. Crompton & Co., Ltd., for an electric installation at Nassau, the capital of the Bahamas, has been accepted, in the face of great American competition.

DARTFORD.—The Urban District Council has accepted the following tenders :—Chamberlain & Hookham, Ltd., for the meters required up to June 30th; S. W. Gibson & Co., wiring for condenser pumps and bath pump, £22 15s. 6d.; Hodgson & Stead, Ltd., maintaining weigh-bridge at refuse destructor, £3 per annum.

DUBLIN.—At the meeting of the Corporation last week, the following tenders for the new electrical plant recommended for acceptance by the Electricity Committee were discussed :—Messrs. Ferranti, switchgear and feeder panels at £829 and £185 respectively; British Electric Transformer Co., transformers at £1,698; Messrs. Richardson, Westgarth & Co., boiler plant at £7,071. The Lighting Committee recommended the tender of Messrs. Babcock & Wilcox for plant as the lowest, but Messrs. Richardson, Westgarth & Co. wrote stating that an opportunity had been afforded to Messrs. Babcock & Wilcox to amend their tender, and asked for a like opportunity to put in a revised tender. Mr. Hutchinson said that it was against the principle of fair play to allow any tender to be amended, and he moved the matter be sent back to the Committee with instructions to advertise for fresh tenders. This was seconded and passed.

GLASGOW.—The acceptance of the following tenders is recommended by the Electricity Committee.—The Temperley Coal Transporter Co., at £2,520, for a coal transporter; Messrs. Donald Clarke & Sons, coal bunkers at Port Dundas station, at £550: British Thomson-Houston, for two Tirrill regulators, at £1,630, one for Port Dundas Station and one for St. Andrew's Cross station.

MELBOURNE.—The tender of Messrs. Johnson & Phillips for the supply of insulated cables at £240 has been accepted. The tender of Messrs. Lawrence & Hanson for a 500-kw. motor generator has been recommended by the Electric Supply Committee for acceptance.

COMPANIES' MEETINGS AND REPORTS

ABERDEEN SUBURBAN TRAMWAYS CO.—The report for the half-year ended July 31st gives the net profits of £855, giving, with the addition of the amount carried over from the last account, a balance of £2,422. The negotiations with the Corporation of Aberdeen for a supply of electric energy, after the expiry of the present agreement, have now reached an advanced stage. Arrangements are being made for a reference to an arbiter to be appointed by the Board of Trade to fix the price at which the current will be supplied. The directors recommend a dividend of 2 per cent. on the paid-up capital, with £1,000 transferred to renewals and depreciation account, and £755 carried forward.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD CO.—The report of the Brighton and Rottingdean Tramroad Co. for the year ended December 31st, 1907, states that the balance of revenue at December 31st, 1907, was £2,132. Sundry creditors absorbed £714, debenture interest £984, and the amount due to capital account was £434. The meeting is to be held on October 3rd, at Brighton.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—The half-yearly meeting was held last Thursday, Mr. W. Mooney presiding. The available balance, after providing for debenture interest, was £868, and a half-yearly dividend on the 5 per cent. preference shares would absorb £475, leaving a balance of £393, which it was proposed to carry forward. The Chairman said that the working of the lines was satisfactory, and the receipts had increased by 15⅔ per cent. as against the preceding year. The expenses had, however, increased, mainly owing to the rise in the price of coal by an amount more than sufficient to pay a dividend of one per cent. on the ordinary shares. The report and accounts were adopted.

LANARKSHIRE TRAMWAYS CO.—At the ordinary general meeting last Friday, Mr. A. R. Monks, who presided, stated that the company was in a position to pay a dividend at the rate of 6 per cent. per annum on both the share capital issued prior to January 1st, 1908, and the new issue of shares from date of payments of instalments to June 30th, 1908. The traffic receipts had exceeded by over £4,000 the income for the corresponding six months of 1907. The shares offered in February last had been fully subscribed for by the shareholders, and the proceeds had been utilised in constructing the recent extensions, which, however, owing to delays in passing the plans by the local authorities and late delivery of certain materials, had not been opened as early as had been anticipated. It was not proposed to incur further capital expenditure on plant extensions at the generating station, and negotiations were pending for a supply of current for the new lines from another source. The and accounts were adopted.

SOUTH AMERICAN LIGHT & POWER CO.—Mr. F. H. Jackson presided at the fifth annual meeting last Friday. The company were to be congratulated on having reached the dividend-paying stage. The net amount at the credit of profit and loss account was £2,309, and they proposed to pay 2 per cent. But for certain items with which the directors had had to deal the dividend would have been larger. The balance to be carried forward was £167. The report and accounts were adopted.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £62 10s. to £63 per ton (last week, £62 to £63).

ARMORDUCT MANUFACTURING CO.—We are informed that the company can now supply from stock ceiling rose fittings fitted with the Wilton grip continuity system.

BANKRUPTCIES, LIQUIDATIONS, &c.—The examination in bankruptcy of James Allan Wilson, electrical engineer and mill furnisher, of Kilmarnock, was held last Thursday. Assets were given as £310 and liabilities at £2,450. The debtor had started business about five years ago with obligations for borrowed money to the extent of £400 or £500, and stated that about £800 of it was never in the business at all, part of it having been borrowed to pay accommodation bills, and there were about £200 of bad debts. He believed he had lost a good deal by leaving mill furnishing alone and trying to develop the electric business, which had never paid him.

The statement of affairs of Mr. W. T. Garnett, of Undercliffe House, Bradford, who carried on business as an electric cable and wire manufacturer at Barkerend Mills, Bradford, as W. T. Garnett's Cable Company, shows liabilities are estimated at £94,942, of which £31,330 are expected to rank. The assets are estimated to produce £8,129. The debtor attributes his failure to depreciation in the value of real estate, heavy bank charges, unsuccessful trading owing to the Eastern crisis, lack of working capital, and fluctuation in the price of copper; also losses on investments, and the initial expenses of commencing and developing certain businesses.

A petition has been presented for the winding-up of Electrical Instrument Manufacturers, Ltd., by W. J. Berrill and A. E. Berrill, trading as Gordon & Gotch, advertising agents, and will be heard at Edmonton on September 14th.

It has been resolved to wind up the Private Telephone Co., Ltd., voluntarily. A meeting of creditors of this company was held at 29 Chancery Lane yesterday.

Creditors of the Blackpool Electric Tramways (South), Ltd. (in liquidation), are requested to send particulars of their claims to Andrew McGowan and J. McWilliam, 43 Castle Street, Liverpool, before October 5th next.

EDISON & SWAN UNITED ELECTRIC LIGHT CO.—In a competition held at Leyton on Bank Holiday, the Ediswan Fire Brigade were successful in winning the fourth prize in the One Man Manual Drill, also first prize in the Five Men Manual Drill. They also tied with Wanstead Fire Brigade for the "Vincent Challenge Shield," but lost this in the re-drill. The "Vincent Challenge Shield" is held for one year by the brigade making the fastest time in the Two Men and Five Men Drills.

MISCELLANEOUS CITY NOTES

ASCOT DISTRICT GAS & ELECTRICITY CO.—An interim dividend at the rate of 5½ per cent. per annum has been recommended for the half-year.

CAMBRIDGE ELECTRIC SUPPLY CO.—An interim dividend at the rate of 5 per cent. per annum has been recommended for the half-year.

ELECTRICAL ENGINEERING IN GERMANY

Sir Francis Oppenheimer's Consular Report

THE following are extracts from Sir Francis Oppenheimer's Consular report on the Frankfort district :—

The Proposed Government Monopoly for Electrical Power.—A Government monopoly for the supply of electrical power has been suggested. In the electric industry combinations have taken place for years, but they have been combinations for the manufacture of electrical appliances. When the electrical industry was still the spoilt child of the German investor, electrical works (compelled uninterruptedly to increase their production to cope with the increasing demand) was readily supplied with the necessary capital, but after the first seven fat years a crisis ensued because the reduced consumption revealed a critical overproduction, which naturally led to underbidding and financial collapses. The crisis was overcome chiefly with the aid of combinations. These combinations were effected either by connecting various branches of manufacture in one concern, or by the combination of several works in the same branch of manufacture; the former effected a reduced cost of production—the latter chiefly a reduced cost of administration and general expenses. Such is the origin of those gigantic combinations mentioned in former reports : Allgemeine Electricitäts Gesellschaft with Union; Siemens with Schuckert; Felten Guilleaume with Lahmeyer. Like the important combinations in the mining and iron industries, these combinations in the electrical industry had undoubtedly a great bearing upon the combinations in the banking world, the gigantic credits often required by these industrial combinations being beyond the capacity of any of the older individual banks.

Of syndicates proper there are comparatively few in the electrical industry on account of the great variety of manufacture, nor does it appear that the public has been sufficiently accustomed in the various branches to certain recognised standard articles. Where such standard goods have been insisted upon, syndicates have been established, *e.g.*, in incandescent lamps, cables, &c. In other branches, such as electrical motors and apparatus for continuous current of great power, there are at best loose price conventions. The nearest approach to a trust exists among the manufacturers of accumulators.

There is no doubt that the electrotechnical industry, suitable to the German frame of mind, has become essentially a German industry; it is claimed that the German success is due to a very keen inter-German competition. So far as the suggestion of a State monopoly for electrical power goes, fears are raised from within the industry; such a monopoly must interfere with the freedom of motion within the industry. The great argument so far put forward in favour of the scheme of a Government monopoly lies in the easy decentralisation which could thus be effected in the interests of industry at large, for wherever a Government power station is established there any industry could, of course, obtain cheap power; such stations would undoubtedly become numerous in view of the extended railway system which probably would be the first to profit from such a monopoly.

The substitution of electrical power for steam power on railways with extended systems has already become the subject of official inquiry, and quite recently the Bavarian Government has worked out statistics showing the quantity of power needed. The Prussian State railways intend to introduce electrical power in place of steam on certain lines, but the change will not be effected for some time to come. The financial aspect of this scheme of a general Imperial monopoly has not yet been definitely examined, but it is believed that the various State railway systems obtaining the necessary power from the Imperial power monopoly would alone yield a sufficient basis to vouch for a satisfactory Imperial balance-sheet in future.

New Attempt to Use Motion of Tide for Production of Electricity.—Statistics have repeatedly been published to show how soon the coal supply in the various coal-producing countries will be exhausted if the demand continues to increase proportionately to the past. Such reports animate a further search for the utilisation of electrical power in preference to steam. Even the motive power of electrical works is replaced by water power. Heretofore this has been chiefly effected by the natural water power of rivers. Recently new endeavours have been made similarly to utilise the motion of the tide. In Hamburg a company has been started (capital £2,000) styled the "Wasserkraft Anlage" to work a new electrical plant with the aid of the tide. The works are to supply Cuxhaven with electric light and to run an electric railway. According to present calculation the electric current ought to be supplied at a greatly reduced price.

The French Association for the Advancement of Science.—Among the Papers read before the Congress of the French Association for the Advancement of Science at Clermont-Ferrand were the followding :—The transmission of energy from the Rhone to Paris, by MM. de la Brosse and Blondel; electric locomotives, by M. de Marchena; two Papers on wireless telegraphy, by Lieut. Tissot; the electric arc, by M. Cheneveaux; photometry, by M. Guillez; and a report by MM. Bergonié and Turpain on the measurement of high-frequency currents.

ELECTRICAL NOTES IN CEYLON

(By Our Own Correspondent at Colombo.)

CEYLON, at the present moment, is enjoying a wave of prosperity, and steady development is taking place in all the staple industries, with the inevitable result that public means of communication are also expanding. The telegraph system of the colony shows a steady growth, but, of course, the more rapid expansion is seen in the telephone system. Colombo now possesses a fair overhead system, comprising two central exchanges with 300 subscribers and 30 miles of route. Cheap flat rates are in vogue, and since in the tropics a telephone is much more of a necessity than at home, a large future growth may easily be predicted. It is reported that next year the Government intend to put in an underground system in the more central parts of the town.

* * *

Of recent years there has been an agitation in favour of telephone systems for the hill capital of Kandy, and also the famous health resort of Newera-Eliya. It is now reported that next year a commencement will be made with the provision of exchanges for these two towns, as well as the provision of trunk lines to Colombo, a distance of 75 and 135 miles respectively.

* * *

An electric lighting scheme has recently been put forward for Newera-Eliya. It is but a small scheme, and it is believed that this has been sent home for report by the Government experts in London.

* * *

There are, of course, the existing installations of electric tramways in Colombo, and the lighting system by the same company, but these do not show any signs of rapid expansion. Perhaps the fact that overhead distribution in the suburbs is not allowed, and that 50 cents (8d.) per unit is charged for private lighting, may have something to do with this. At a place like this the new metal-filament lamps should have a very good field, but for some reason—not, let us hope, because this is only one of our Colonial possessions—the possible trade in such lamps appears to have been quite overlooked by British firms.

NEW COMPANIES

MERSHON INSULATOR (HIGH TENSION) SYNDICATE.—This company was registered on August 8th, with a capital of £20,000 in £1 shares, to acquire certain rights in connection with an invention relating to improved high-tension insulators and to carry on the business of an electric power and supply company in all its branches. The subscribers are M. McQueen and St. J. G. Miller. Private company. The first directors (to number not less than two nor more than seven) are R. D. Mershon (permanent, subject to holding 500 shares), H. W. Fox, M. F. Armstrong, W. A. Wills, W. Praeger, and A. Scott. So long as Earl Dysart is a shareholder he may nominate one director, W. Praeger being his first nominee. Remuneration, one guinea each per board meeting attended, and 5 per cent. of the net profits dividend.

SPARKS (SHEFFIELD).—This company has just been registered with a capital of £1,000 in £1 shares, to carry on the business of electrical and mechanical engineers, manufacturers of and dealers in electric, magnetic, telephonic, telegraphic, and other appliances, and apparatus, &c. The subscribers are :—E. C. Clayton, B. Lake, Mrs. M. J. Horton, H. T. Magness, E. Swinden, J. M. Mason, J. B. Kesteven. Private company. The number of directors is not to be less than two nor more than five; the first are Mrs. M. J. Horton, E. C. Clayton, and B. Lake. Registered offices, 111 Broomhall Street, Sheffield.

THORPE METER SYNDICATE.—This company was registered on August 13th, with a capital of £9,000 in £1 shares (3,000 founders'), to acquire from W. B. Thorpe an invention relating to an electricity meter, and to turn the same to account. The subscribers are :—W. B. Thorpe, 3,000 founders'; H. P. Miles, 1,000 ordinary. Private company. The first directors are J. M. Gatti, H. P. Miles, and E. A. de Paiva, J.P. Registered office, 11 Victoria Street, S.W.

W. SEYMOUR.—This company was registered on August 14th, with a capital of £1,050 in 1,000 preference shares of £1 each, and 1,000 ordinary shares of 1s. each, to adopt an agreement with W. Seymour, to acquire the business carried on at 1 and 7 Ellis Street, Sloane Street, S.W., and to carry on the business of electrical, mechanical, sanitary, gas, hot water, and motor engineers, founders, smiths, workers of electricity, &c. The subscribers are :—Mrs. E. G. E. Seymour, A. F. Davies. Private company. Table "A" mainly applies. Registered offices, 1 Ellis Street, Sloane Street, S.W.

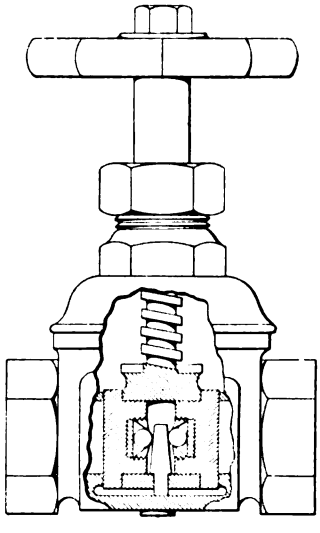
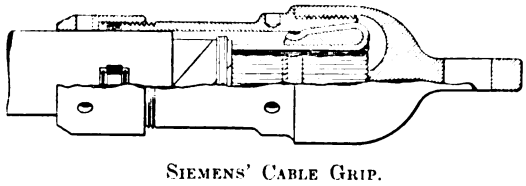
CATALOGUES AND PAMPHLETS RECEIVED

BOILER MOUNTINGS, &c.—A well-got-up and illustrated catalogue of steam specialities is to hand from Messrs. Joseph Shaw & Son, Ltd., of Albert Works, Huddersfield. One of the principal features of the list is the series of Shaw patent improved steam valves in various forms. In these valves, the valve seat is made of a specially prepared metal calculated to resist the action of steam, and, being considerably harder than the valve, cannot easily be injured by grit or other material coming between the seat and valve. If from any other cause the seat should get damaged, it can be reground or replaced with a new one at a trifling cost, without removing the body from its position. The valve is made separate from the spindle, and, being in a concentric form, it makes a most reliable metal-to-metal joint that will resist any pressure. The valve is simple and strong, and not liable to get damaged; it will always find its true centre on the valve seat, as under all conditions it will accommodate itself to any variation in the spindle caused by wear or strain. Attention should also be drawn to the parallel pattern of valve shown in the accompanying figure. In the valve, which has a straight full thoroughfare equal to the capacity of the pipes, the discs are pressed to the seats by a wedge operating on the ball bearings, fixed in the centre of the discs, thus giving an equal pressure on both faces, and in a simple manner making a perfectly fluid-tight joint. All these valves can be fitted with valves and seats of a special alloy known as "Nico" metal when they are required for highly superheated steam. Other boiler accessories in the list include asbestos-packed cocks, water gauges, fusible plugs, steam traps, and a variety of other apparatus.



Shaw Patent Parallel Steam Valve.

CABLE ACCESSORIES.—A very complete new catalogue of cable accessories has been issued by Messrs. Siemens Bros. & Co., Ltd., of London and Woolwich. The introductory portion comprises well-arranged tables of conductor sizes, weights, resistances, &c., and other useful figures, after which is a fully illustrated section including all kinds of jointing material. The portion devoted to tools and cable-laying appliances is also very complete. We illustrate a special form of cable grip which the firm have introduced to obviate the danger which sometimes occurs of damaging heavy lead cables whilst drawing through conduits. The use of these grips ensures that the strain of pulling-in comes direct upon the conductor and not on the lead casing of the cable. At the same time they ensure that the end shall be kept perfectly watertight by a rubber-packed gland, so that the cable can be drawn through water without any risk. The conductors of the cable, after having been bared, are passed through the loose cone piece, turned over and then bound down, and it will be seen from the illustration that the wires thus turned over are held between the cone and the steel of the grip; therefore, the greater the strain put on the cable the tighter the grip will hold. Attention should also be drawn to the special insulating material, known as "Ohmulite," which

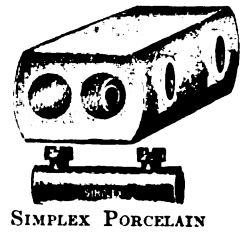


Siemens' Cable Grip.

the company manufacture for all kinds of electrical work. It can be moulded into any form required or made up into sheets. It can easily be drilled, sawn, or worked on a lathe. The material does not become soft or plastic at any temperature, but takes a slight impression at 80° C. It is quite non-hygroscopic, insoluble to all ordinary solvents, practically unaffected by water, sea water, mineral oil, castor oil, and dilute sulphuric acid, and it will not readily ignite. Ohmulite has a tensile strength of about 2,000 lb. per square inch of sectional area, and a dielectric strength of about 150 volts per mil. The latter portion of the catalogue contains particulars of testing sets and instruments, which are dealt with more fully in separate lists.

CEILING ROSES.—A new leaflet relating to ceiling roses is being issued by Messrs. A. P. Lundberg & Sons, whose specialities in the way of wall plugs we had occasion to refer to last week. The newest pattern is known as the "Biflex" ceiling rose. This is fitted with a novel type of terminal, which allows the fitting to be threaded on to the leads, and in the case of the loop-in type plenty of slack to be brought through, and the ends of the wire twisted and properly attached without cutting, as is often necessary with the ordinary types of pillar terminals used for looping-in purposes. Another pattern is the "Triplex," with three contact plates, and can be used for a variety of purposes with two-way switches, &c., and similarly a quadruplex ceiling rose is made with four contact plates. In the "Multiplex" design, there is a common contact plate in the centre, with provision for five track circuits. An arrangement which should be useful in some circumstances is the "detachable" ceiling rose, in which the flexible cord is connected to a detachable piece, with pin contacts similar to an ordinary wall plug, and provided with fuses, the whole being enclosed in the ordinary ceiling-rose cover. With this arrangement, in renewing a fuse there is no need to work in an inconvenient position on the top of a ladder, but the fuse-carrying part may be detached and the renewal done away from the base. During wiring or re-decoration of the ceiling, only the base need be fixed, and the other parts kept out of the way of the workmen and re-attached on completion. A ceiling rose, combined with a "Dot" wall plug, is also listed.

DISTRIBUTION BOARDS AND INSULATED CONNECTORS.—The latest progress sheet issued by Simplex Conduits, Ltd., contains particulars of an inexpensive pattern of distribution board, with bridge fuses in teak case and brass front, and with tumbler switches for each circuit outside the case. Another item is the porcelain connector illustrated herewith, which should be found useful in many installations for making connection between small wires. These connectors will fit into any simplex standard rectangular or circular box. They may also be used behind back plates for making connection to fittings and brackets.



Simplex Porcelain Connector.

CONTACT VOLTMETERS, SIGNAL LAMPS, &c.—We have received from the Union Electric Co. an advance copy of a list which they are issuing devoted to contact voltmeters, relays, signal bells, and lamps, of Messrs. Hartman & Braun's manufacture. There has always been a demand for a reliable contact voltmeter, and the present apparatus, with its carefully designed contacts and oil damper, fulfils all the requirements, both for direct- and alternating-current circuits. In order to excite solenoids, &c., requiring a considerable current, it is necessary for the contacts in the voltmeter to be relieved from the full duty, and this is achieved by the use of special relays, having very ample contact surfaces, and thus permitting heavy currents to flow and be interrupted without harm or loss of reliability. In order to show either that the contact voltmeter is on the maximum or minimum pressure contact, a signal bell has been designed, combined with coloured signal lamps.

INSULATORS, &c.—A new price list is being issued by the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., of insulators, fittings, and tools for telegraph and telephone lines. A large number of porcelain insulators for overhead lines are illustrated, including special iron-hooded insulators. Other items are brackets, iron poles, and fittings, and various tools and appliances for use in erecting aërial lines.

TROLLEY WIRE.—A new leaflet from the British Insulated & Helsby Cables, Ltd., contains illustrations representing the Prescot non-fouling trolley wire, fitted with a straight line mechanical ear. The special advantages claimed for this wire are non-fouling fittings, no bumping or arcing, no crystallisation of the trolley wire, reduced pressure on the trolley boom, considerable saving in trolley wheels and wire, and low cost of maintenance.

WIRES AND CABLES.—The latest cable catalogue from Simplex Conduits, Ltd., contains particulars of three qualities of cables and wires, described respectively as "competition quality," "equal to best grade association," and "chemically, electrically, and mechanically equal to association cable." Several patterns of flexibles are listed, including a special "weather-proof" twin cable covered with thick seamless rubber tubing. Jointing material, Leclanché cells, and dry cells are also dealt with, and also special bell and telephone cables and wires.

SUMMARY

The annual report of the Chief Engineer of the British Engine, Boiler, & Electrical Insurance Co., Ltd., for the year 1907 contains a large amount of information of much interest to manufacturers and users of electrical machinery. The rate of breakdown was rather lower among generators and dynamos, and rather higher among motors, than in 1906. Continuous-current machines broke down more frequently than alternating-current machines, but the average cost of the breakdown was much less for the former cases than for the latter. Details of twenty-four representative cases are included in the report. Much interest attaches to the detailed reports that are published, explaining the causes of these accidents, which, it is said, are quite typical. The rate of breakdown among steam engines during the year was considerably less than during the previous year. The reduction in the number of main shafts broken is remarkable. Among gas and oil engines there is a serious increase in the number of breakages of valves and valve gears, but there is an encouraging reduction in the number of broken cylinders and pistons. Two explosions of boilers in electricity works are recorded. The loss of life caused by the fracture of pipes through water-hammer effects was heavier than usual. (Page 347.)

Some experiments have been made recently in Berlin on an electrically-propelled fire-engine. The results of these experiments show that the cost of running and maintaining an electric engine is somewhat less than that for a steam engine, and very much less than that for a horse-drawn engine. The engine was equipped with hub-motors on the back wheels, and much trouble was experienced with the tyres on these wheels. Four further engines are being constructed. (Page 352.)

The new twin-screw steamer *Orcoma* of the Pacific Steam Navigation Co. has a very complete electric lighting and power installation. The generating plant consists of four 65-kw. 100-volt continuous-current generators, direct coupled to high-speed engines. Some 1,500 glow lamps are employed, and a large number of fans driven by motors of from 8 h.p. downwards are installed. The applications of electric power in the galleys and sculleries are very numerous, and include electric plate and glass washers, knife- and boot-cleaning machines, and potato-peelers. (Page 352.)

The effect of the revocation clause of the new Patents Act which came into force last Friday is reviewed, and the procedure necessary in order to obtain the revocation of a patent which is not worked in this country is outlined. The same article deals with the

Digitized by Google

present position of metal filament lamp manufacture in this country. (Page 353.)

THE first single-phase railway to be constructed in Norway was opened in July last. Power is obtained from a water-power station at 15,000 volts three-phase, and converted to 6,600 volts, 25 cycle, single-phase for the contact line. The rolling stock comprises three Westinghouse single-phase locomotives, and one motor-car. A large proportion of the traffic consists of truck-loads of copper ore from the copper mines in Meldalen. The power station also supplies power to the mines and towns in the district. (Page 355.)

MESSRS. DICK, KERR & Co. are introducing an interpole traction motor, particularly intended for heavy service and where extensive use is made of electric braking. The leading features in the design are described. (Page 357.)

A DESCRIPTION of Messrs. J. H. Holmes & Co.'s works at Newcastle is given on p. 358.

THE "Medhurst" field telephone set is described on p. 361.

AT a large electrically-driven rolling mills in Sweden an interesting method of equalising the demand on the generating plant is employed. The supply is three-phase, and a battery is employed in connection with the load-equalising arrangement. A wattmeter relay in the alternating mains regulates the field of the exciter of a booster connected with this battery in accordance with real power variations of the load, and not, as is usual, with the current. A D.C. machine is connected to the battery 'bus-bars, and this is coupled to a synchronous machine connected to the three-phase 'bus-bars, from which the mill motor circuits are taken. Either of these machines can act as a generator or motor, and thus the battery is charged when the load drops and discharges when the load rises, supplying the surplus energy required through the A.C. machine. (Page 363.)

A SHORT illustrated article gives particulars of the telephone exchange system at Messrs. Debenham & Freebody's. (Page 365.)

WE publish a list of exhibitors at the Manchester Electrical Exhibition, supplementary to the list printed in our issue of August 20th. The total number of exhibitors is now about 230. (Page 365.)

IN a recently issued British Consular Report, containing a collection of notes from various parts of Mexico, there are a few statements of some interest to manufacturers of electrical machinery. Repeated references are made to the futility of sending out catalogues in the English language and with English prices, and the scarcity of British commercial travellers is commented on. (Page 365.)

SOME information with regard to applications of electricity in agriculture in Germany is furnished in an American Consular Report. Motors are employed which can be utilised for a variety of purposes, and are not always permanently connected to one machine, as each class of work is only done for a limited period each year. The applications include oil-cake breaking, pumping, threshing, chaff-cutting, bruising, haulage, unloading hay, smithy and cartwright work, ploughing and reaping. (Page 366.)

Two of the patent specifications which were published last Thursday relate to the problem of increasing the specific resistance of metal filaments in order that the length of the filament for a given pressure can be reduced; the object of this is, of course, to render possible the manufacture of high voltage, low candle-power lamps. The first patent describes a method of obtaining alloys of tungsten with other refractory metals, by mixing powdered tungsten with their oxides also in the form of powder, and forming filaments with the help of a binding agent which is subsequently volatilised. The introduction of silver into the tungsten filament is proposed in the second of these specifications. (Page 367.)

MR. R. G. BLAINE writes us with regard to the review of his book on the slide rule. (Page 367.)

AN article in an American contemporary describes some experiments made on a tungsten filament lamp, to determine the nature and extent of the alleged "overshooting" or excessive brilliancy on switching on the lamp when cold. Conclusive evidence of a considerable rush of current and a corresponding excessive brilliancy lasting for about one-tenth of a second is given. An oscillograph record of the brilliancy and current on a 25-cycle alternating-current circuit showed not only the same excessive current kick and rise in brilliancy, but also the alternate heating and cooling of the filament. (Page 367.)

UNDER ELECTROMETALLURGY AND ELECTROCHEMISTRY we give abstracts of two German patent specifications relating to processes for the manufacture of oxides of nitrogen by electrical methods. The influence of the silent electric discharge on explosive gas mixtures, according to some recent experiments, appears to be greatest when one of the constituents of the mixture is oxygen. This is probably due to the formation of ozone. There is little effect upon mixtures such as hydrogen and chlorine. There are a large number of electric furnaces now working; some of these require over 1,000 electrical horse-power. A new form of cadmium cell for experimental work is described. An electrical process for the production of hypochlorite disinfecting fluid has given great satisfaction in Poplar. The theory of the E.M.F. of primary cells is also among the subjects dealt with in this section. (Page 368.)

THE patent specifications which were published by the Patent Office on Thursday last include one by M. J. MCVITTIE for an electromagnetic safety device for holding up a lift car on breakage of the ropes or other means of suspension. The DEUTSCHE BECK-BOGENLAMPEN GES. have a patent relating to an improved lifting magnet for use in connection with arc-lamp mechanisms, and another by A. ECKSTEIN and others describes a reverse current circuit breaker, which, it is stated, will operate even with very heavy reverse currents without danger of reversal of polarity. The control of single-phase traction motors suitable for working with both alternating and continuous current is the subject of a specification by E. F. ALEXANDERSON, and one by F. PORSCHE describes a system of petrol-electric transmission for motor vehicles, by which the demand for power is automatically regulated by a decrease in the speed of the motor owing to an automatically produced reduction of the motor air-gap. Two patents relating to alloys for metal lamp filament are dealt with separately. No patents of electrical interest expire during the current week. (Page 369.)

WE give Colonel Yorke's report upon his recent inspection of the Ealing tramways. No fault is found with the condition of the track. Some information with regard to the position at Ealing between the London United Tramways, Ltd., and the Council is also given. (Page 346.)

EXHAUSTIVE life tests are being carried out at Beckenham on metal filament lamps for street lighting, the lamps being run night and day.—The Local Government Board has refused to sanction a loan to the Brighouse Corporation in connection with the replacement of the generating

plant by transforming plant; the Council has abandoned generating electricity itself in favour of taking a bulk supply.—A scheme of decorative electric lighting at the Scottish National Exhibition was inaugurated last week.—The National Electric Construction Co. are endeavouring to secure consent to the use of the overhead trolley system instead of the surface-contact system upon the Folkestone, Sandgate, and Hythe Tramways.—The differences between the Battersea Borough Council and the London County Council with regard to tramways in Battersea have been overcome.—Public telephones have been installed in fourteen branch libraries in Manchester.—Electricity supply is now given in Northfleet by the Gravesend Corporation. A short while ago, after signing an agreement, the Gravesend Corporation desired to withdraw, but were threatened with a legal action.—A 50-c.p. 220-volt metal filament lamp is to be placed in each of the 1,045 lamp-posts in Wimbledon. (Pages 371-3.)

The East Indian Railway Company require a 600 kw. three-phase alternator, together with gas engine. —Tenders are invited for large quantities of telephone and telegraph material in Australia.—The Salford Corporation require lighting and power feeder and distributor pillars.—Tenders amounting to over £12,000 have been accepted by the Adelaide Municipal Tramways Trust. (Pages 373-4.)

The General Electric Company of Russia have declared a dividend of 4 per cent. for the past year against 3 per cent. for the previous year. (Page 375.)

A company, called the Deutsch Südamerikanische Telegraphengesellschaft, has been formed in Cologne with the object of laying and working a submarine cable from Germany *via* Teneriffe to the German colonies on the west coast of Africa and the east coast of South America. The cable will be made by the Nord-deutsche Seekabelwerke of Nordenham, and be subsidised by the German Government. (Page 376.)

The descriptions of typical breakdowns, which are included in the annual report of the Chief Engineer of the British Engine, Boiler & Electrical Insurance Co., Ltd., for the year 1907, should prove a useful supplement to the accumulated experience of manufacturers and users of electrical machinery. Of the twenty-four examples selected by the Chief Engineer, Mr. Michael Longridge, as representative of the accidents to motors and dynamos which have come under his notice, there must be some which will either warn the designer or manufacturer of previously unrecognised sources of danger, or will suggest improvements for avoiding the occurrence of any particular accident in the future. It may also happen that light will be thrown on a nearly forgotten breakdown, the cause of which was never ascertained. Many of the breakdowns described only emphasise more strongly suggestions of improvement which previous experiences have given rise to; for instance, the further protection of open and semi-enclosed motors by a fine meshed network cover, so as to prevent the many accidents due to the presence of foreign bodies in the gap; and, again, the use of pure mica in preference to micanite for the insulation between commutator segments. Among the accidents due to bad mechanical construction, two or three are mentioned as being caused by relative movement between armature and commutator; there thus appear to be still cases of the mechanical design of the armature having been left to men unacquainted with the exact nature of the magnetically produced stresses acting on the armature conductors and transferred from these to the core. A particularly interesting case of breakdown is that of a continuous-current shunt-wound motor-transformer, which, when started up one evening, attained to such an excessive speed that the steel binders were broken by reason of the centrifugal force. On examination it was found that one end of the shunt winding had slipped out of its terminal; and it was presumed that an attendant, who had cleaned the machine in the morning, had pulled it out with a duster. For this to have been the case, the fuses must have been inordinately heavy, for the motor would have to have started up without any field except the residual magnetism, and the cross-magnetising effect of the armature would have tended to wipe out any residual magnetism. There is also the possibility that the brushes were accidentally shifted to give a lead instead of a lag, so that the magnetising effect of the armature would provide the necessary field; this may be regarded as very improbable. We therefore incline to the opinion that the shunt winding was, at any rate, lightly connected at first, so as to allow the motor to speed up, and that as the speed rose the vibration shook the wire off the terminal. We cannot remember an accident of this nature before; presumably in most cases the overload release on the starter or the fuses would have protected the motor. The necessity of adequately protecting the field connections of continuous-current shunt motors is emphasised, however, and this simple detail of construction hardly receives the attention it deserves.

The meeting of the British Association for the Advancement of Science opened at Dublin yesterday, and to-day the real work of the various sections begins. In the Engineering Section, papers on a variety of subjects are down for reading and discussion, but the time has not yet arrived when this annual meeting is of equal importance to engineers as it is to physicists and to that portion of the general public which takes keen interest in abstract science. The meeting of the British Association is recognised by the leading men of science as an occasion for the discussion of new discoveries and on the significance of the latest research. Hypotheses are put forward tentatively to receive destructive criticism or to be promoted into the ranks of working theories. The various schools of scientific thought engage in friendly duels, and the result of their being brought into contact is that divergent views frequently become convergent, and the object of the Association, the advancement of science, is always clearly attained at each meeting. On the other hand, the Engineering Section can do far less to advance the science of engineering. The engineer is essentially a commercial man nowadays, and he looks on his profession mainly from the revenue-earning aspect; it is not to be expected that he will give the world the benefit of any undeveloped or partially developed ideas before he has placed himself in a position to earn the full reward to which he naturally considers himself entitled. Thus it is that the papers in "Section G.—Engineering" are largely on work and subjects that are not new to the engineering world. Many contributions are sent in by authors with axes to grind, and they are too often no more than a *réchauffée* of papers that the authors have previously read before their own engineering societies, presented

Digitized by Google

with a view to obtaining the further publicity hospitably accorded by the daily press in the latter end of the summer. We do not desire to suggest that any of the papers down for reading this year have been submitted with these objects; on the contrary, there are some of considerable general interest and precisely of the character suitable for a British Association meeting. It would, however, be of great advantage if the larger proportion of the papers discussed were of a broad nature, dealing with general tendencies in the engineering professions and industries rather than the particular constructive work of individuals or firms. Subjects should be chosen which are of simultaneous interest in several branches of engineering, and the papers coming within the domains of any particular section of the engineering industry should be of such a character that they invite discussion by men whose work lies in adjoining territories. Nowadays, the successful engineer must be a specialist during his working hours, but he can derive enjoyment himself, and extend benefit to his neighbours, by allowing himself this relaxation during the British Association holiday week.

IT has been thought desirable in certain cases on the Continent to connect up the tramway systems of two or more industrial towns by a double line of track through the surrounding country, and to keep up a light but fairly frequent service of cars between these towns. The case of the line between Vienna and Baden may be cited as an example. This line, which we described some nine months ago, is about 18 miles long, and in order to take advantage of the economies to be effected by alternating-current transmission and operation, the cars were equipped with alternating-current commutator motors of the compensated series type which work equally well when supplied with continuous current. The cars were thus enabled to run on the tramway systems in both towns, as well as on the twelve-mile long alternating-current section of the line. If, however, the motors are operated as series motors on both direct and alternating current, the pressure of the alternating-current supplied to the motors must ordinarily be lower than that permissible when the motors are operating on direct current, because of the increased commutation difficulties met with in alternating-current operation. This leads to many undesirable consequences, one of which is the necessarily increased size of connecting wires, controller contacts, and switch gear. A solution of this problem has been put forward by Mr. C. F. W. ALEXANDERSON, who, it will be remembered, read a paper some few months ago before the American Institute of Electrical Engineers on a new single-phase motor. The principles of his system are given in the brief abstract of a patent specification in our Patent Record of this week's issue. Mr. Alexanderson proposes to use commutator motors so constructed that they can work as ordinary series motors when supplied with continuous-current, but as repulsion motors when supplied with alternating current. As explained in our abstract of the patent specification, the change-over is effected by short-circuiting the armature for alternating-current working. Commutation difficulties do not become so overwhelming on an increase of voltage when repulsion motors are used, and so a terminal pressure of double the terminal pressure for continuous-current working may be employed, the possibility of extra strain on the insulation of the stator windings being avoided by earthing the middle point of the secondary of the main transformer, and connecting the terminals of the motor circuits to points on the winding on opposite sides of the earthed point. The working alternating-current pressure may thus be twice the working pressure for continuous-current. Special arrangements are provided whereby the proper proportions of the compensating and inducing ampere-turns, for continuous-current and alternating-current working respectively, are maintained, and as the short-circuiting of the armatures is done without breaking the series connection between the armature and the field windings, the short-circuit connection between the armature brushes has to carry only the difference between the armature current and that in the field windings. The same advantages can be obtained if an auto-transformer is used instead of a double winding transformer for transforming the contact line pressure down to the motor pressure. The combination of continuous and alternating current traction has considerable application for inter-urban tramways and light railways, for even in cases in which the towns or villages to be connected have no tramways at present running, the high-tension trolley line of the single-phase systems will hardly be allowable in the streets, although it may be used to advantage on the outside roads.

FROM an article which we publish this week, it is seen that investigators are actively engaged in endeavouring to find an alloy with a higher specific resistance than tungsten or tantalum for use as a filament in metal filament lamps. Doubtless a considerable amount of tedious experimental work will have to be gone through before something absolutely satisfactory is arrived at, but we should by no means despair of success in the near future, which will enable a 200-volt lamp to be put on the market with a filament of reasonable length and not of too microscopic a diameter. Alloys are notoriously inconsistent with regard to temperature coefficients. While the best resistance materials for measurements are "german silver" alloys, which can be made to have no variation in specific resistance within the ordinary ranges of temperature, a very different condition of affairs occurs when alloys are raised to white-hot temperatures, so it is not merely a question of finding an alloy which has a high specific resistance and a high melting point. At these high temperatures, also, many alloys are unstable. Although the problem is difficult, however, it is, as we have said, one about the early solution of which we need be by no means despondent.

Telephony in the Alps.—Last night's *Evening Standard* and *St. James's Gazette* states that Italy will shortly possess the highest telephone station in the world. Work has been commenced on the new telephone line to the Margherita hut, near the summit of Monte Rosa, 15,217 ft. The new observatory on the Col d'Ollen will be first connected with the Lombardy valley, and then the line will be continued to the summit of Monte Rosa. Queen Margherita of Italy, who contributed largely to the erection of the observatory and hut which bear her name, has been the chief supporter of the Alpine telephone line. Swiss critics, however, state that the innovation will be a failure, as it is impossible to plant posts in glaciers and masses of ice which are ever in a state of slow motion.

SOME TYPICAL BREAKDOWNS AND THEIR CAUSES

THE annual report of the Chief Engineer of the British Engine, Boiler, and Electrical Insurance Company, Ltd., for the year 1907, contains one section devoted entirely to accidents that have happened to electrical machines. This section includes descriptions of twenty-four representative cases. In his introductory remarks to this section of the report, Mr. Michael Longridge (the Chief Engineer) says:—

The fact that the breakdowns of dynamos and motors in 1907 exceeded the number in 1906 by 18·1 per cent. in number, and by 16·3 per cent. in cost, proves that the insurance of electrical machinery is a benefit to the user, while the further fact that the number of machines insured at the end of 1907 exceeded the number insured at the beginning of the year is evidence that the benefit is appreciated. The rate of breakdown was rather lower among generators, and rather higher among motors, than in 1906. The exact figures are 1 in 18·7 among generators, and 1 in 7·9 among motors. The corresponding figures for 1906 were 1 in 16 and 1 in 8·2. Again, as in 1906, the rate among continuous-current machines was much higher than among alternating, but, on the other hand, the average cost of each breakdown was much less, so that the company's practice of charging practically the same rates of premium for both types of machine has been justified.

The proportions in which the various parts of the machines are thought to have caused or initiated the breakdowns of 1907 are tabulated below:—

Description of Part which is believed to have failed first.	Generators.		Motors.	
	1906.	1907.	1906.	1907.
	Per cent.			
Armatures and rotors	50	35	44	38
Magnet coils and stators	11	7	14	14
Commutators and brush gear	20	34	28	30
Miscellaneous	19	24	14	18
	100	100	100	100

Starting Switches and Controllers.	1906.	1907.
	Per cent.	
Resistance Coils	48	60
Contacts and switch arms	10	8
Automatic apparatus	17	13
Miscellaneous	25	19
	100	100

The causes of these breakdowns were probably as follows:—

	Dynamos.		Motors.		Starters.	
	1906.	1907.	1906.	1907.	1906.	1907.
	Per cent.					
Accidental	15	8	9	4	22	9
Dirt and neglect ...	14	25	19	28	11	16
Age and deterioration	21	23	25	23	23	27
Bad work or design	23	21	18	18	9	8
Overloading	0	0	2	1	7	5
Unascertained	27	23	27	26	28	35
	100	100	100	100	100	100

The following examples have been selected from each class as illustrations of the causes and results of breakdowns. They are said to be quite representative of the daily experiences of the Company's inspectors:—

1.—*Protected three-phase alternating* 50-*h.p. motor, one year old, taking current at* 500 *volts, and running at* 750 *revolutions per minute.* The inspector found that six of the stator coils had been completely stripped, and about 15 of the rotor coils badly damaged. He supposes that some foreign substance got into the machine when it was running, and simply demolished all the coils which were in its path, for the case was full of small bits of copper. The rotor was damaged just in one place, and from the nature of the damage great force had been expended at that point. He surmises that something caught in the rotor winding, and went round the coils. Although the motor was of the protected class, the inspector said it was quite possible for things capable of doing the damage to get in. There was no question of the rotor windings having been lifted by centrifugal force, as the binders were intact.

2.—*Two-pole shunt-wound enclosed motor for driving the scrapers of an economiser, marked* 4·5 *amperes,* 230 *volts,* 1,300 *revolutions.* The insulation had been rubbed off the windings at the driving end of the armature by some hard substance which had got wedged between them and the back flange of the frame. Twelve coils were burnt, and on stripping these off others below were seen to be charred, so that the armature had to be rewound. The inspector found nothing wrong with the frame, except that the flange was broken off one of the vulcanite bushes in the front plate, through which the leads from the brushes were carried to the main terminals fixed on the outside of the frame. This piece may have caused the damage.

3.—*Four-pole totally-enclosed series-wound* 8-*h.p. motor, two years old, driving a winch in a shipyard with current at* 480 *volts; speed,* 700 *revolutions per minute.* The fuse, a No. 16 S.W.G. tin wire, having melted, one of the company's inspectors was sent for to examine the motor. He found the solder all round the end connections of the armature conductors partly melted, and on taking out the armature four coils were seen to be completely burnt out. Wedged into the space between two of the conductors and the end of the core was a piece of cinder, which no doubt was the cause of the trouble. How it got there in an enclosed motor is a mystery. It is suggested that the armature must have been set down upon it or rolled over it at some time when taken out, and that movement of the conductors while the motor was running had caused it to rub through the cotton covering and short circuit the coils.

4.—*Semi-enclosed two-pole centre-hung shunt-wound* 2½-*h.p. continuous-current motor, taking current at* 500 *volts, and driving a fan in a smithy at a speed of* 2,400 *revolutions per minute.* According to the statement of the attendant, a belt of flame ran round the commutator when he started the motor. When he stopped it he found the remains of two rats wedged between the armature and the frame, but could discover no injury to the conductors. By testing, however, the company's inspector found a break in one of the end connections, close to the commutator, which had no doubt caused the sparking. Whether one of the rats was accountable for the breakage was uncertain, but the attendant decided to guard against a similar mishap in the future by covering the motor with a "rat-proof box."

The following case, however, shows that a box is not an infallible protection:—

5.—*Alternating-current* 12-*h.p. motor, protected by shield fastened to the frame, and enclosed in a water-tight iron box.* The insulation of the top coil of the stator winding, carrying current at 250 volts, was burnt, and the coil "earthed." The cause of the damage was saturation of the coil by soft soap. The box, like other similar boxes in the works, had no lock, and had been appropriated by the workmen and used as a locker for stowing away tools, aprons, dinners, plates, and cans, and, among other things in this particular box, a handful of soft soap, which had been stuck on top of the framing of the motor, and had run down on to the stator windings through the joint between it and the protecting shield above referred to.

6.—*Two-pole totally-enclosed shunt-wound* 4-*h.p. Lundell motor, taking current at* 230 *volts, and running at* 1,100 *revolutions per minute.* The company's inspector was sent for because smoke was issuing from the joints of the carcase. He examined it, ran it, and tested the insulation without discovering any fault. He then had it opened, and discovered that the smoke had come from the ignition of a quantity of oil, dust, and dirt which had accumulated upon the bottom of the circular magnet coil by sparks from the brushes, and that the sparking had been caused by one of the carbon blocks getting jammed in its brush holder. The insulation of the magnet coil was also slightly charred. This was patched up, the brush gear put in order, and the motor cleaned and started. Since then it has given no further trouble.

The above is said to be quite a typical case. Fires inside motors started by the ignition of collections of fluff and dust are not uncommon. The following is a case of bad construction aggravated by neglect:—

7.—*Four-pole shunt-wound semi-enclosed motor, about two years old, giving* 80 *h.p. at* 500 *revolutions per minute with continuous current at* 500 *volts, and protected by two No.* 16 *S.W.G. copper wires fusing with* 332 *amperes or* 2½ *times the maximum current supposed to be carried by the machine.* The fuse melted, and on examination two of the armature coils were found burnt. The remaining coils were saturated with oil and very dirty. The insulation of the commutator segments was also burnt close to the spokes through oil and dust settling between the spokes and short-circuiting them. This insulation,

Digitized by Google

instead of being carried up a short distance, say, ¼ in. or so between the spokes, ceased at the ends of the bars, leaving very narrow wedge-shaped openings between the edges of the spokes to hold oil and dust. The machine was so damaged by dirt and neglect that the armature had to be entirely rewound, and the commutator rebuilt and re-insulated. It was only accepted for insurance about 11 months previous to the breakdown, and was then in good condition. It seems, however, that it had then just had the benefit of a thorough repair in consequence of a similar breakdown at the end of its first year's work.

8.—*Two-pole continuous-current shunt-wound motor transformer, working in a sub-station of a lighting supply, receiving* 44 *amperes at* 1,080 *volts, and transforming to* 110 *volts. Normal speed,* 470 *revolutions per minute.* When started from the central station on the evening of the breakdown, the armature gained sufficient speed to break one of the steel binders at the high-tension end, and spread the conductors till they jammed themselves fast between the pole pieces. On examination it was found that one end of the shunt winding had slipped out of its terminal. One of the attendants who had cleaned the machine in the morning declared that the wire was then in place, and suggested that it must have been shaken out of the terminal by vibration when the machine was started. It is far more likely that he pulled it out with the duster or waste he was using, for the wire had simply been slipped under the binding screw, and not bent round or over the terminal block.

The case is mentioned because the number of shunt wires broken or pulled out of their terminals proves that such wires ought to be better protected and more efficiently secured than they generally are.

9.—*Two-pole compound-wound dynamo,* 10 *years old, giving* 1,000 *amperes at* 120 *volts, driven direct by a Willans engine, running at* 350 *revolutions per minute.* The armature bars were connected at the end next the engine to "butterflies," or pieces of copper shaped like commutator segments, with two lugs of unequal length, alternate bars being connected to the long lug of one butterfly and to the short lug of the next. The butterflies were clamped between a collar and clamping ring in the same way as ordinary commutator segments, and insulated from each other and from the clamping rings and frame by micanite sheets and rings. The machine was first insured in 1901. Early in 1906 the insulating ring at the outer end of the butterflies broke down, and, being accessible, was easily repaired. About a year later flashing was seen inside the armature behind the butterflies, but it became necessary to unsweat the armature bars and take off the butterflies to get at the inner insulating ring, where the fault appeared to be. As the commutator was worn very thin, the owners decided to have it replaced at the same time, and accordingly it also was disconnected from the armature bars. The covering of these was then seen to be completely pulverised, and incapable of bearing the least disturbance, so it became necessary to renew it. Thus through the deterioration resulting from 10 years of nearly continuous running day and night, the repair of a small defect in the insulation of the butterflies necessitated complete rewinding of the armature.

The following examples show that pure mica is preferable to micanite for the insulation between commutator segments:—

10.—*Two-pole shunt-wound open-type* 12-*h.p. motor, three years old, driving the hoisting winch of a* 10-*ton crane with current at* 220 *volts.* Owing to the melting of the solder joining the armature coils to the commutator lugs, the armature was sent to the makers for repair, and at their works the inspector saw it. The insulation of the armature coils proved on testing and careful examination to be quite satisfactory, but the commutator segments were short-circuited by carbon dust, which had worked in between the flakes of mica of which the micanite plates between the bars were made. The short-circuits were not only at the surface, but extended into the interior of the commutator.

11.—*Four-pole compound-wound dynamo, three years old, giving* 90 *amperes at* 250 *volts when running at* 850 *revolutions per minute.* The commutator contained 153 segments, insulated with one exception by mica plates. The exception had micanite. The two coils in connection with this segment were burnt out and had to be replaced. The cause was a short-circuit across the micanite insulation, produced by carbon dust and oil which had penetrated into the micanite. The other segments were quite as dirty, but the mica plates between them had kept up the insulation.

This is not the only trouble with commutators, as will be seen below.

12.—*Four-pole shunt-wound enclosed motor, about three years old, rated to take* 150 *amperes at* 110 *volts at* 750 *revolutions per minute; in use on a* 15-*ton crane.* The commutator was built on a cast-iron sleeve, to which the segments, 76 in number, were secured by an iron clamping ring, 4⅜ in. diameter, and a nut the same diameter, and ¼ in. thick, as shown by Fig. 1. The ring was provided with a keyway to prevent it

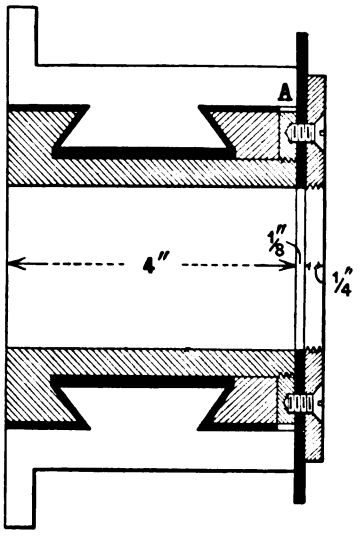

FIG. 1.—SECTION THROUGH COMMUTATOR, SHOWING CAVITY A, INTO WHICH CARBON DUST WORKED.

from turning when the nut was tightened, but no key had been fitted, nor was there any corresponding keyway in the sleeve. The micanite ring for insulating the copper segments from the iron clamping ring was carried over the edge of the ring, but not over the nut. Outside the nut there was a micanite washer, 6½ in. diameter and ⅛ in. thick, and outside this again an iron washer 5⅜ in. diameter and ¼ in. thick, held by six ¼-in. screws. The figure shows clearly that any slackening of the clamping nut or shrinking of the micanite washer would allow carbon dust to get into the space under the ends of the commutator bars, whence it could not be removed. As might be expected under such conditions, short-circuits were established between the commutator bars, and the fuses melted. The inspector who was sent for to examine the motor found short-circuiting had occurred between the copper bars and the iron clamping nut, as well as between the bars themselves. Eighteen bars in all were burnt, most of them at the point *A*, showing that the clamping nut had slackened, or that the micanite ring had shrunk and allowed carbon dust to penetrate between it and the ends of the copper bars. The clamping nut was also severely burnt. Inquiry by the inspector elicited the information that this motor and others similarly built had broken down in the same way before. In rebuilding the commutator care was taken to fix the clamping ring, lock the nut, and continue the micanite insulating ring over it as well as over the clamping ring.

13.—*Four-pole series-wound motor, two years old, rated at* 110 *amperes* 240 *volts, driving the live rolls in front of a rolling mill, and consequently reversing several times per minute.* Two of the armature conductors were burnt. The armature was sent to be repaired. When tested, after the repair, a large number of short-circuits were found between the commutator bars. As these could not be cleared the commutator was taken off, and it was then seen that the bars were from 1/16 in. to 1/8 in. deeper than the mica plates between them, and that in many places arcs had formed across the spaces. These short circuits had no doubt caused the damage to the armature coils. It was seen that one of the driving lugs on the sleeve which carried the commutator was broken, and that the armature spider was very loose upon the shaft. When the two taper pins which were driven in at each end, half into the spider and half into the shaft, were slackened, and the armature lifted, the shaft dropped out. Its diameter was 1/32 in. less than that of the armature bore. A new shaft had to be fitted, and the commutator had to be rebuilt.

14.—*Series-wound motor of the same size as that described in the last paragraph.*—This was constructed by the same makers, and used for the same work, but in this case the spider was secured upon the shaft by two taper keys, instead of two taper pins, one at each end of the hub, and by a set

Digitized by Google

pin through the hub at the driving end. After working about two years a crack was noticed in the driving end of the hub, and the hub was seen to be loose on the shaft. On taking out the set pin the shaft dropped out of the armature. Measurement showed that the bore of the hub was nearly 1/32 in. larger than the diameter of the shaft, and examination of the surfaces showed that the two had been in contact and rubbing diametrically opposite to the two keys, and not elsewhere, and that the sides of the keys were worn by movement. It is uncertain when or how the end of the hub was first cracked, but it seems likely that the time was when the shaft was put into the armature, and that the cause was over-driving the tapered key. That is probably also the reason why the set pin was put in. A new shaft was made and fitted into the old spider, the cracked end of the hub being hooped to save rewinding the armature.

15.—*Two-pole overhung compound-wound dynamo, about seven years old, driven at a speed of* 940 *revolutions per minute by a belt from a gas engine, and rated to give* 110 *amperes at* 250 *volts.*—The armature had a smooth core drum wound with bar conductors, which were soldered direct to the commutator lugs. The commutator, 7 in. diameter and 7½ in. long, consisted of 68 segments built upon a cast-iron sleeve fixed by a feather key ½ in. broad and ¼ in. thick, sunk ⅛ in. into the shaft. Attention was called to the machine by sparking at the brushes, and one of the commutator lugs was found broken at its junction with its base. When the commutator was taken off, seven other lugs were seen to be partly broken, the feather key to be badly fitted, and the cast-iron sleeve to be slack upon the shaft. The armature bars, strange to say, showed no signs of movement upon the core. The breakages were evidently caused by relative movement between the armature and commutator resulting from slackness of the latter and vibration set up on the belt by varying angular velocity of the engine flywheel.

16.—*Series wound six-pole enclosed motor, driving a* 10-*ton overhead travelling crane, rating* 30 *amperes,* 500 *volts,* 400 *revolution per minute.*—The armature was taken out on account of the fuse melting. The coils at the pinion end were found to have been rubbing against the back end plate of the carcase, and two of them to have fused. To replace them it was necessary to rewind the armature. The damage was caused by motion of the latter along the shaft. The spider on which armature core and commutator were built was held only by a one gib-headed key 14 in. long, ½ in. wide, and 5/16 in. thick, bedded upon a flat on the shaft. There was no collar or nut. The jerks caused by reversing the motion of the crane and the vibration of the gearing had loosened the key and left the armature free to slide along the shaft.

17.—*Four-pole shunt-wound* 4-*h.p. motor, eight years old, running at* 600 *revolutions per minute, and taking current at*

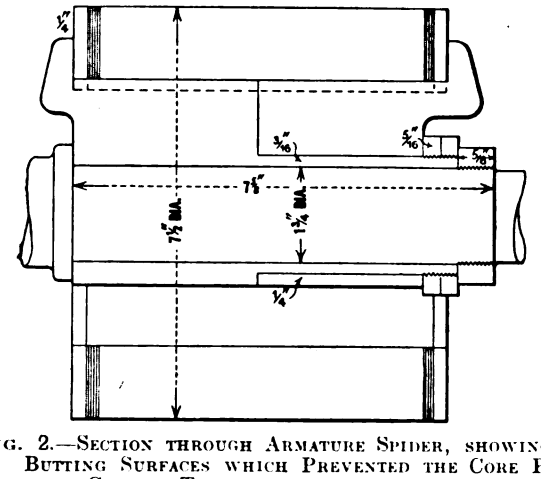

FIG. 2.—SECTION THROUGH ARMATURE SPIDER, SHOWING THE BUTTING SURFACES WHICH PREVENTED THE CORE PLATES BEING GRIPPED TIGHTLY.

400 *volts.*—The motor drove a 5-ton travelling crane. There were frequent breakages of the connections between the armature conductors and commutator, which, it was thought, were probably due to relative motion between the armature core and commutator owing to one or the other being loose on the shaft. The owners were advised to send the armature to the makers to have the loose part secured; but, wishing to use the crane, they kept the machine at work. However, it again broke down, and was sent to the makers to be repaired. The inspector found that all the leads to the commutator were either broken or had been broken and repaired, and ordered the armature to be stripped. It then appeared that the spider which carried the core plates was made in two pieces as shown by Fig. 2. The longer piece was fixed by a key and secured by a nut, the shorter by two weak nuts each 5/16 in. thick. Thus the only driving force upon the core plates was the friction resulting from the pressure of the two flanges of the spider upon them. Had the spider been properly constructed with a slight gap between the ends of the two pieces, this pressure could not have exceeded the maximum which one of these weak nuts could have exerted, but as the ends of the two pieces touched it may have been much less. It is little wonder, therefore, that the core plates moved and carried the conductors with them. The spider was also loose on the shaft, for when the nut at the end was unscrewed the shaft dropped out. The advantages of this system of construction are not self-evident, but, if used, the two pieces should be made like the two halves of a claw coupling and forced together by a good strong nut.

18.—7-*h.p. three phase motor of foreign manufacture, driving the hoisting winch of an overhead crane with alternating current at* 190 *volts.*—The three leads to the slip rings were fused. On examining the rotor it was found that the core plates had been threaded upon the shaft and a ring shrunk on at each end to hold them. There was no key or feather to prevent them turning. The conductors were led over the ends of the core through a hole in the shaft, which was hollow, and out at the end to the slip rings. This hole had sharp edges and was not bushed with insulating material. The consequence was that the rotor got loose and rocked upon the shaft, rubbing the insulation of the leads where they entered the shaft and short-circuiting them.

19.—*Two-pole underhung compound-wound dynamo, five years old, giving* 350 *amperes at* 115 *volts when running at its normal speed of* 750 *revolutions per minute.*—The dynamo stood in the engine-room and was driven by ropes from a counter shaft. The rope drive was outside the engine-room, and the shaft which carried the driven drum was supported by a bearing in a wall box in the engine-room wall and joined to the end of the armature shaft by a face coupling with four ⅝ in. bolts. The clear distance from the end of the coupling next the armature to the bearing for the armature shaft was 1¾ in. The diameter of the end of the shaft where the coupling was keyed was 2½ in., and the keyway was ⅝ in broad and 5/16 in. deep. The shaft was of steel. It broke close to the coupling in a plane at right angles to the axis, as though cut by a saw held against the coupling. The fracture was partly old, and had evidently commenced at the circumference and gradually extended. The cause cannot be stated with certainty, but it is suggested that during the five years the machine had been at work the bearing had got a little out of level and allowed the shaft to bend slightly while running, and that the edge of the coupling had thereby been pressed into the skin of the shaft and started a skin crack, which, after the manner of slight cracks or scratches in steel under alternating stresses, had gradually worked its way through the cross-section of the shaft. Had the shaft been enlarged or grooved where it entered the coupling, the skin of the shaft could not have been indented by the edge of the coupling.

20.—*Four-pole shunt-wound ventilated motor,* 7-*h.p.,* 14½ *amperes,* 400 *volts,* 1,000 *revolutions per minute, driving machine tools.*—Fuse when insured, one No. 16 S.W.G. tin wire, subsequently replaced by a cartridge "Mordey" fuse of 25 amperes. The inspector, after the breakdown, found that two of the armature conductors were broken, one close to the commutator lug, and the other so close to the core as to necessitate lifting the coil, and as this could not be done without lifting the other coils the repair meant rewinding the armature. He also learnt that the makers had been sent for some months before on account of bad sparking, and had then warned the owner that the machine was overloaded. The inspector measured the current required to run all the machinery which the motor drove, and found it to be 20 to 21 amperes. The owners afterwards admitted that they had added some machines since the insurance was effected.

21.—*Four-pole compound-wound enclosed motor,* 11-*h.p., driving a hammer with current at* 210 *volts.*—Fuse, two No. 22 S.W.G. copper wires, subsequently replaced by one of No. 20 S.W.G. When the inspector was making his usual periodical call he found the motor in a very unsatisfactory state, and the fuse red-hot, but not melted. He told the owner that the armature ought to be taken out and thoroughly repaired, and that the machine should be more lightly worked. The next day he called again to see what had been done, and found the motor still working with the fuse wire red. He had it

c 2
Digitized by Google

stopped and opened for examination. The armature and field coils were so hot that he could not keep his hand upon them; indeed, the latter were just on the point of burning. All the armature connections were completely or partly unsoldered from the commutator lugs, and the solder was splashed about the inside of the casing. The commutator segments were short-circuited in several places and badly fused. How the motor could have run in such a condition is extraordinary. The owner declared that the motor could not be overloaded, as he had been advised that a 5-h.p. motor would be sufficient for the work, and moreover the fuse had not melted. To this the inspector replied that the evidence of overload was that the fuse was habitually red hot, and that but for the intermittent character of the load it would have melted. This resulted in a dispute between the company and the owner, which was finally settled, the hammer being given lighter and less continuous work, and with the exception of some flats on the commutator and an occasional broken armature connection the motor has worked without serious trouble.

22.—*Two-pole centre-hung shunt-wound enclosed motor, four years old, running at* 1,000 *revolutions per minute and receiving current at* 500 *volts from the outer wires of a three-wire supply.*—The motor was used for driving a hoist in a six-storeyed building, and was placed in the basement close to the bottom of the lift well with the commutator end of its spindle about 6 in. from the wall. The frame was earthed, and two lamps were connected in parallel with the field coils to act as a discharge-resistance. These should have been fully alight so long as current flowed through these coils, but for some days previous to the accident they had occasionally shown a dull red light, indicating an intermittent "earth" on the field coils. One day, when the cage, which was descending loaded, had nearly reached the ground, a loud explosion was heard, and the front end plate of the carcase, which carried the bearing for the commutator end of the armature shaft, was fractured round the circumference and blown along the shaft till arrested by the wall, on which it left its mark. The rocker for carrying the brush spindles was also broken, and the oil blown out of the oil well at the driving end of the armature shaft. The armature conductors were not broken, but subsequent inspection showed that their insulation was damaged and that the lower field coil was saturated with oil, its insulation deeply burned, and the coil earthed to the former on which it was wound, and to the frame. The state of this coil had no doubt caused the intermittent glowing of the lamps. Most likely it was the cause of the explosion also, for in default of any other explanation it is suggested that a combustible gas must have been given off while the insulation of the field coil was being burnt away, and that this gas must have been ignited by arcing or by sparking at the brushes. The nature of the material was not ascertained, as the stuff was unfortunately thrown away by the firm employed to rewind the coil before the inspector could secure it, and the firm from whom the machine was originally bought (it was of foreign make) either would not or could not obtain the information. The oil used for lubricating was castor oil.

23.—*Four-pole shunt-wound motor, taking* 22 *amperes at* 400 *volts. The armature ran at a speed of* 1,000 *revolutions per minute and drove a printing machine through back gear.*—While working the armature began to wobble, bringing the steel binding bands into contact with the pole faces. It was taken out and put into a lathe, where one of the company's inspectors examined it and came to the conclusion that it was loose on the shaft or that the shaft was broken. The latter turned out to be the case. The crack commenced at the square end of the keyway and extended more than halfway through the shaft in a plane nearly at right angles to its axis. The shaft was 2 in. in diameter, and the keyway $\frac{1}{2}$ in. wide and $\frac{1}{8}$ in. deep. Whether the sharp corner at the end of the keyway started the crack is uncertain; if it did it is probable that the vibration set up by the speed-reducing gear extended it, for the gear ran very badly.

24.—*Four-pole series-wound* 3-*h.p. enclosed motor, one year old, driving the cross-traverse motion of a* 15-*ton travelling crane with current at* 240 *volts. Fuse, copper,* 26 *amperes.*—The four field coils were totally burnt out, but the armature was uninjured and the fuse did not melt. No cause for the damage could be found, but the inspector was informed later that the armature had always started with a jerk, and had run at the same speed on all the contacts of the controller. It seems clear, therefore, that there must have been some intermittent fault in the controller, which was of the drum or tramway type, cutting the resistance and armature out of circuit and leaving the field coils short-circuiting the mains. The inspector ordered four new coils from the makers of the motor and left the owners to slip them on to the pole pieces and connect them. In due course these arrived and were put on, but the motor would not run, so the inspector was sent for again. On testing, he found that the sequence of the four poles was N.N.S.S. instead of N.S.N.S. The mistake was easily corrected by turning the two top coils round. When this had been done the motor started and ran well in one direction, but on turning the controller in the opposite direction to reverse the motion the armature refused to move, and the contacts sparked furiously. After some trouble in tracing out and making a diagram of the connections to the controller, the inspector found them to be as shown in Fig. 3, so that when running forward the current, after all resistance had been cut out, passed through both field coils, controller, and armature by the path $+abcdefghi-$, but when the controller was moved in the opposite direction the current took the path $+abcji-$. The armature was thus cut out of circuit, and the field coils left connected across the mains. Hence the refusal of the armature to start and the sparking at the controller contacts. He altered the connection i and f as shown in Fig. 4,

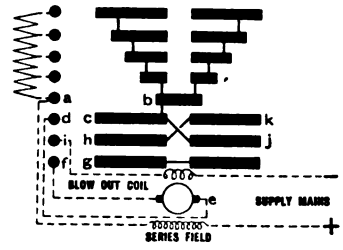

FIG. 3.—INCORRECT.

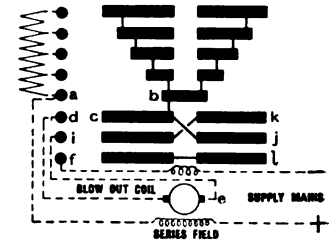

FIG. 4.—CORRECT.

Diagrams showing Motor Controller developed, with incorrect and correct Connections.

so that the path of the current when the motor was reversed became $+abcjiedklf-$. This case shows the importance of providing clear diagrams of connections with all kinds of starting switches and controllers. Without such diagrams many mistakes are certain to be made.

That section of the report which is devoted to breakdowns of steam, gas, and oil engines is of more general interest, but the following summary of the accidents reported and their causes is of interest:—

The rate of breakdown was 1 in 11·7 among steam engines and 1 in 11·1 among gas and oil engines, as against 1 in 8·1 and 1 in 12·4 last year. The proportions in which the various parts of the insured engines which broke down in 1907 caused or initiated the breakdowns are given in the last columns of the following tables. The other columns give the percentage for 1906 and the average for the previous 24 years:—

STEAM ENGINES.

Description of parts which are believed to have given way first.	24 Years previous to 1906.	1906. Per cent.	1907.
Valves and valve gear	21·0	23·3	28·0
Spur gearing	14·8	12·0	10·2
Air-pump motions	10·4	9·9	10·2
Air-pump buckets and valves	7·3	6·9	4·0
Columns, entablatures, bedplates, and pedestals	6·9	8·6	7·7
Cylinders, valve chests, and covers	5·2	6·1	7·2
Bolts*	4·7	0·0	0·0
Parallel motions and links	4·5	2·7	5·6
Main shafts	4·4	5·2	2·6
Pistons, with their covers, rings, and bolts	3·2	3·4	5·6
Governors and governor gear	2·6	1·7	2·0
Connecting rods, straps, and bolts	2·4	5·6	2·0
Piston-rod crossheads	2·3	2·7	3·6
Flywheels	2·0	1·7	2·0
Air pumps and condensers	1·9	2·1	3·1
Piston rods	1·8	2·7	2·0
Crank pins	1·3	0·4	1·6
Cranks	1·1	0·0	1·0
Beams and side levers	0·9	0·4	1·6
Gudgeons in beams	0·8	0·8	0·0
Main driving ropes or belts	0·2	1·3	0·0
Total wrecks, cause not ascertained	0·2	2·1	0·0
Second motion shafts	0·1	0·4	0·0
	100·0	100·0	100·0

* These bolts do not include bolts in pistons, air-pump buckets, valves, connecting rods, valve gear, and other moving parts, the bolts in these parts being tabulated with the parts to which they properly belong.

Digitized by Google

GAS AND OIL ENGINES.

Description of parts which are believed to have given way first.	Average previous to 1906.	1906.	1907.
		Per cent.	
Valves and valve gear	32·5	28·7	43·3
Cylinders and cylinder ends	16·6	16·7	13·5
Pistons	11·7	6·5	2·7
Connecting rods and their bolts	11·2	12·0	8·1
Main shafts	5·0	15·7	4·7
Governors and governor gear	4·4	7·4	7·4
Silencing boxes and exhaust pipes	4·4	2·8	1·4
Flywheels and driving drums	4·3	4·6	4·7
Clutches and couplings	3·5	0·0	0·0
Frames and pedestals	2·8	0·0	4·0
Bolts*	2·6	0·9	1·4
Total wrecks, cause not ascertained	1·0	1·9	0·0
Main driving ropes or belts	0·0	1·9	0·0
Miscellaneous	0·0	0·0	5·4
Gas-producer plants	0·0	0·9	3·4
	100·0	100·0	100·0

* These do not include bolts in pistons, connecting rods, valve gear, and other moving parts, the bolts in these parts being included with the parts themselves.

The causes of these breakdowns may be roughly classified as under :—

	Steam Engines.	Gas Engines.
	Per cent	
Accident or causes unascertained	27	44
Old defects or deterioration by wear and tear	38	17
Weakness, bad design, workmanship, or material	19	18
Negligence of owners or attendants	16	21
	100	100

The following comments are made on the above table :—

The increase in the number of breakdowns of steam engines traceable to failures of valve gears is probably the result of increase in speeds and number of parts. The reduction in the number of breakages from spur gearing is the natural consequence of the substitution of rope and direct driving for the older system of transmission. The steady increase in broken cylinders is due principally to the use of steam at temperatures and pressures higher than the parts can safely bear. The reduction in the number of main shafts broken is remarkable and inexplicable. In gas and oil engines the increase in breakages of valves and valve gears is not satisfactory, and demands the serious attention of makers of these engines. If all side shafts were fitted with ring lubricators and levers made of wrought iron or good cast steel the percentage in the table would be reduced. The reduction in broken cylinders and pistons is encouraging, and marks the progress which is being made. Connecting rods proved less destructive than usual, probably because of improvement in design, particularly as regards strengths of bolts. Breakages of crank shafts were fewer than in 1906.

The two following examples are of particular interest :—

High-speed inverted vertical triple-expansion engine, running at 383 revolutions per minute, with cylinders 14 in., 20½ in., and 30 in. diameter by 14 in. stroke, direct coupled to a dynamo.—The exhaust steam from the condensing cylinder was led through a valve in the exhaust pipe to a jet condenser, or, alternatively, when this valve was closed, through an automatic atmospheric valve to the atmosphere. The condenser was cleared by a pair of Edwards air pumps, driven by an electric motor, receiving current from the dynamo driven by the engine. It drew its own water from a pond, whose surface was about 15 ft. 7 in. below the middle of the cylinders. Thus, in the event of the air pumps ceasing to clear the condenser the water from the pond would be forced into the low-pressure cylinder if the pressure in it were more than 6·7 lb. per square inch below that of the atmosphere upon the surface of the pond. The usual practice in shutting down was to close first the engine stop valve and then the valve in the exhaust pipe to shut off the condenser. On the evening of the breakdown this practice was adhered to, but the engine, instead of coming gradually to a standstill as usual, stopped suddenly as the driver was about to close the valve in the exhaust pipe. The cause of the sudden stoppage was an inrush of water from the condenser into the low-pressure cylinder, which bent the piston and stretched the bolts in both ends of the connecting rod. It is commonly believed that some special guardian protects children and drunken men. Surely that guardian must have drawn this engine also under the covering of its wings; otherwise it could hardly have escaped disaster during the 12 months it had run. Every day there must have been a race between the water and the man. Would the water reach the cylinder or the man the valve in the exhaust pipe first? It must have been a really sporting chance on which it would have been hard to obtain odds from anyone "in the know." No; the least reflection would have shown the driver that the valve he closed first was precisely the valve he should have closed last. If he had destroyed the vacuum, either by closing the injection cock or by shutting off the condenser, or by opening the atmospheric valve before touching the engine stop valve, the accident would not have happened.

High-speed inverted vertical non-condensing double-acting two-crank engines, with cylinders 9 in. and 15½ in. diameter by 8 in. stroke, direct coupled to a dynamo running at 425 revolutions per minute; boiler pressure 140 lb. per square inch.—The engines were started in 1900. In 1905 the crank shaft was found to be slightly bent and was replaced, the old shaft, however, being kept as a spare after being made true by skimming up the bearings in a lathe. In 1907, after having run less than two years, the new shaft broke through the web of the crank next the dynamo, and a third shaft was ordered, the spare shaft above mentioned being used to keep the engine running. The cause of the breakage was not ascertained. The company's inspector thought the shaft was hard and brittle. The makers of the engine replied that it was made from the same quality of steel, about 32 tons tensile strength, as they always used for shafts. They further gave it as their impression that the breakage must have been caused by the bearings for the engine and dynamo shafts being out of line or level, and advised that these bearings should be aligned and adjusted before the new shaft was put in. The dynamo armature was accordingly lifted; the brasses were relined with white metal and levelled, and the new shaft bedded upon them. Eight weeks afterwards the new shaft broke in the same place as the old one. The two surfaces of the fracture were quite close when the inspector saw the broken shaft, but when it was taken out two patches of white metal were found embedded in the crack. Of course, they must have come from the bearing next the flywheel, but it is difficult to understand how they got into the position where they were found. The makers of the engine again attributed the breakage to the bearings being out of line; but Mr. Longridge thinks they were mistaken, and that it resulted from some wrong treatment of the steel during manufacture. He adds, however, that it is possible, with a speed of 425 revolutions per minute, that it might have been the result of excessive stress produced by cumulative vibrations synchronising with the period of the engine.

According to the information given in the section dealing with boiler explosions, collapses, and other sundry mishaps, there were eight boiler explosions during the year. Two of these occurred in electricity works, and resulted in three deaths and injury to eight persons. The loss of life caused by the fracture of pipes or valve-casings by water-hammer was heavier during the year 1907 than is usual. Six men were killed in this way, three of them by one explosion. The following description of an accident to a water-tube boiler in an electric generating station may be of interest to our readers :—

Babcock & Wilcox water-tube boiler, with nine rows of headers and ten tubes to each header, 90 tubes in all; working pressure 200 lb. per square inch.—The boiler was numbered 3 in a group of four, of which two only, Nos. 3 and 4, were in use, supplying steam to engines generating electricity for lighting. In addition to the usual mountings, the boilers had automatic isolating valves to cut either off from the steam main in the event of the pressure falling below that in the others. On receipt of a telegram reporting an accident to No. 3 boiler, an inspector attended to ascertain the nature and cause of the damage. He found that the tubes in the four lower rows had been red hot, and those in the bottom row partly melted. The cause was clearly deficiency of water, for, apart from the absence of any deposit likely to cause such serious overheating, the blow-off cock was found open. On inquiry, it transpired that the fireman had come on duty at 10 p.m. the evening before, and after that hour he and a switchboard attendant had been left in charge of the machinery. The latter stated that the fireman had not attended to the engines as usual, and that he had been obliged to go to the stokehole several times to complain of insufficient pressure, the justice of the complaint being vouched for by the automatic pressure recorder. Strange to say, he did not notice anything unusual about the man's behaviour until the steam fell rapidly

Digitized by Google

and the lights went out. He then found that the man had emptied No. 3 boiler through the blow-off cock, neglected to feed No. 4 till the water had gone out of the glass, and then drawn the fires of both. The isolating valve on No. 3 had closed and prevented an explosion when the tubes in the bottom row failed. It may be mentioned that some of the tubes which had been red hot were taken out, cut up, and tested by bending, and were found to be perfectly ductile and apparently unhurt.

EXPERIMENTS WITH AN ELECTRICALLY-PROPELLED FIRE-ENGINE IN BERLIN

A REPORT on some experiments on an electrically-propelled fire-engine for the Berlin Fire Brigade is abstracted in a recent number of the *Elektrotechnische Zeitschrift*. The engine, which weighed about 4,500 kg. complete, was provided with a battery of 78 accumulators, with a total capacity of 195 ampere-hours on a five-hour discharge rate. Experiments were also carried out on a steam-propelled engine, built by the same firm as that which supplied the electrically-propelled engine. A petrol-propelled engine was considered unsafe on account of the inflammable nature of the fuel. The electrically-propelled engine was first constructed with a single motor and chain drive on to the back wheels, but experiments with this equipment showed an energy consumption of 84 watt-hours per ton-kilometre, and with this consumption the battery only allowed of a 46-km. run being made on one charge. The single motor and chain drive were then replaced by two hub motors in the front wheels. Each motor had a continuous rating of 7·5 h.p. at 225 r.p.m. With these motors the energy consumption was reduced to 56·4 watt-hours per ton-kilometre, with an average speed of 36 km. per hour. At this rate of discharge the batteries permitted of an 86-km. run being made on one charge. The chief trouble experienced was the wearing of the rubber tyres of the front wheels. After 5,000 kilometres, the outer covers of the front tyres had to be renewed, whereas those of the back wheels were in good condition, although they carried approximately the same load. The tyres were of different makes, but nevertheless the results may be taken to confirm the fact that the unsprung weight of the hub-motors has a bad effect on the life of the tyres.

The engine ran about 108 km. per day on the average; the greatest distance run in one day was 154 km. The battery remained in good condition up to the end of the specified length of test-run, *i.e.*, 10,000 km. After running a further 2,470 km., a capacity test on the battery showed that the capacity had fallen to 117 ampere-hours at a 39 ampere discharge rate, and it was then decided to renew the positive plates.

The following yearly working costs and maintenance charges are based on the results of the experiments made with the two engines. They represent a total distance travelled during the year of 1,500 km. (The average distance travelled by horse-drawn engines is about 1,000 km. in the year.)

	Steam Engine.	Electric Engine.
	£	£
Working costs ... ... (In the case of the electric engine including cost of current and maintenance of battery and motor.)	35·81	30·11
Cost of holding in readiness	20·64	—
Rubber tyres	22·85	22·85
Non-skid covers	5	5
Repairs to engine	2·25	2·25
Total	£86·55	£60·21

The annual cost of running and maintaining the electrically-propelled engine thus works out at £26 less than that for the steam-propelled engine. The annual cost for a horse-drawn engine has been on an average £226, so, in the event of the substitution of electric for horse-drawn engines, a considerable saving would be effected.

It has been proposed to equip the steam-propelled engines already constructed with two small hub-motors and a 150-kg. battery. This would render it unnecessary to always keep the boilers under steam, as the engines could be started out on the battery, and then, after about ten minutes, the steam pressure would be sufficient to run the engine. The favourable results of the experiments have resulted in the city authorities granting £6,675 for the construction of four electrically-propelled engines, and if these prove satisfactory, a larger number may be ordered.

ELECTRICAL EQUIPMENT OF THE PACIFIC STEAM NAVIGATION CO.'S R.M.S. "ORCOMA"

THE following is a brief description of the main features of the electrical equipment of the Pacific Steam Navigation Co.'s new twin-screw steamer "Orcoma." This magnificent vessel of 11,532 tons, the newest and largest of the Company's fine fleet, marks an advance in size and equipment which will make her the finest steamer in the West Coast trade (Chilian waters). Her principal dimensions are:—Length between perpendiculars, 510 ft.; breadth moulded, 62 ft.; depth moulded to shelter deck, 40 ft. 6 in., and 65 ft. 6 in. to the boat deck. Accommodation has been provided for 250 first-class, 200 second-class, and a large number of third-class passengers. The machinery consists of two sets of quadruple expansion four-crank engines, balanced on the Yarrow Slick Tweedy system, having cylinders, 26 in., 37½ in., 53½ in., and 76 in. diameter by 54 in. stroke, with three double-ended and three single-ended boilers for a working pressure of 210 lb. per sq. inch.

The electric generating plant consists of four 65 kw. continuous generators direct driven by high-speed engines with forced lubrication. The generating pressure is 100 volts. The whole of the plant was supplied by Messrs. W. H. Allen, Son & Co., of Bedford. The switchboard, from which are controlled the various lighting and power circuits, is of the Edison & Swan Co.'s make. The ship's lighting comprises 1,500 16-c.p. glow lamps, and three arc lamps for cargo purposes; also one Admiralty type Morse Code signalling lamp. One of the large whistles is controlled by an electrical apparatus which admits of its being operated by a small handle on the navigating bridge. It can, in addition, be switched on to a special clock in the wheel house, which blows the whistle automatically at fixed intervals of every sixty seconds, thus providing a great additional safeguard to the security of the ship in foggy weather. The ventilating plant consists of two 8-h.p. Allen enclosed motors, driving powerful Sirocco fans for ventilating the stokeholds; four enclosed motors by the Electric and Ordnance Accessories Co., of Birmingham, driving fans for ventilating the galleys and lavatories; and sixteen 54-in. ceiling motor fans for ventilating the dining saloons. Eighty-six 9½-in. trunnion motor fans are installed in the first-class state-rooms, all of Messrs. Bergtheil & Young's manufacture.

Another application of electric power is the driving of the laundry installation, which is done by a 5-h.p. enclosed Allen motor. A Waygood passenger lift, connecting the four passenger decks, is worked by an 8-h.p. enclosed Siemens' motor; and there is also an electrically-operated hoist for raising provisions from the refrigerating chambers below. In the galleys and sculleries are installed eight motors for such various purposes as spit-turning, knife-cleaning, potato-peeling, bread-kneading, boot-cleaning, and dish-washing. There is even an electrically-driven bacon-cutting contrivance. Electric heating is represented by radiators, ovens, hot-plates, and irons, and in the barber's shop are to be found electrically-driven hair brushes and fans in connection with the hair-drying apparatus. There is also a very complete system of electric bells throughout the ship, and the principal officers are in close touch by means of a telephonic intercommunication system. The wiring of the steamer was carried out by the builders, Messrs. William Beardmore & Co., of Dalmuir.

International Conference on Electrical Units and Standards.—The President of the Board of Trade has appointed Major W. A. J. O'Meara, R.E., C.M.G., to be an additional British Delegate to the International Conference on Electrical Units and Standards, which is to assemble in London on October 12th next. The names of the members of the Committee, and the general objects of the Conference, were given in ELECTRICAL ENGINEERING, Vol. III., page 894.

THE REVOCATION AND WORKING OF FOREIGN PATENTS

An Analysis of the Revocation Clause of the New Patents Act

Metal Filament Lamp Manufacture

THE revocation clause of the new Patents Act came into force last Friday, August 28th—one year after the Act of 1907 received Royal Assent—and it has been much discussed during the past week. While there is no doubt that the result of the clause will be that several industries in the United Kingdom will be benefited to a considerable extent, and that employment will be found for many thousands of workmen in the development of manufactures and processes that have hitherto been unworked in the United Kingdom, there has been some misconception on many sides as to the actual effect of the clause in question.

In the first instance, it may be pointed out that the new Patents Act came into force at the beginning of this year. It made other alterations in the patent law of this country than those relating to patents not worked in the United Kingdom, principally the creation of "patents of addition" of which advantage has been taken by many patentees during the past eight months, and a revision of the law with regard to compulsory licences, for the application of which, we believe, no occasion has yet arisen. Undoubtedly, however, the part of the Act which is of the greatest importance is that enabling application to be made for the revocation of a patent not adequately worked in the United Kingdom.

In some quarters it has been erroneously assumed that a patent which is not worked in this country will automatically lapse and become void. This is not so. To begin with, four years from the date of the patent have been allowed in which the patentee must put the process or manufacture he describes into effect. But even if the date of the patent is prior to August 28th, 1904, the fact of its not having been worked in the United Kingdom does not in itself invalidate the patent. The exact wording of the clause in question (No. 27) is as follows:—

27.—(1) At any time not less than four years after the date of a patent, and not less than one year after the passing of this Act (*i.e.*, after August 28th, 1908), any person may apply to the Comptroller for the revocation of the patent on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom.

(2) The Comptroller shall consider the application, and, if after inquiry he is satisfied that the allegations contained therein are correct, then, subject to the provisions of this section, and unless the patentee proves that the patented article or process is manufactured or carried on to an adequate extent in the United Kingdom, or gives satisfactory reasons why the article or process is not so manufactured or carried on, the Comptroller may make an order revoking the patent either—(*a*) forthwith; or (*b*) after such reasonable interval as may be specified in the order, unless in the meantime it is shown to his satisfaction that the patented article or process is manufactured or carried on within the United Kingdom to an adequate extent.

Provided that no such order shall be made which is at variance with any treaty, convention, arrangement, or engagement with any foreign country or British possession.

(3) If within the time limited in the order the patented article or process is not manufactured or carried on within the United Kingdom to an adequate extent, but the patentee gives satisfactory reasons why it is not so manufactured or carried on, the Comptroller may extend the period mentioned in the previous order for such period not exceeding twelve months as may be specified in the subsequent order.

(4) Any decision of the Comptroller under this section shall be subject to appeal to the Court, and on any such appeal the Law Officer, or such other Counsel as he may appoint, shall be entitled to appear and be heard.

It is seen that the patent will continue valid unless application for its revocation is made by some interested party. If the business of only one particular British firm or individual is adversely affected by the monopoly granted by the patent, it is—to use an Americanism—"up to him" to take the necessary action; but, if a whole industry is concerned, it may be some time before an agreement is arrived at for joint action being taken by several firms. The procedure appears fairly simple and straightforward, but it is more than probable that it will prove an expensive one in the case of an important patent, and a single firm will not be inclined to bear the whole cost if its competitors in this country will benefit simultaneously.

The first step is to obtain from the Patent Office "Patent Form No. 24," and pay for a £2 stamp upon it. This is simply a formal application for the revocation "on the ground that the patented article (or process) is manufactured [or carried on] exclusively or mainly outside the United Kingdom," giving the name and address of the applicant or applicants, and the number and date of the patent. Simultaneously with, or "as soon as may be after," the return of this form to the Patent Office duly filled in, the applicant must deliver to the patentee or his agent a copy of this application, and must furnish the Comptroller with evidence of such delivery.

The next move has to be taken by the patentee, who, within 14 days from the receipt of this copy of the application, or such further time as the Comptroller may allow, must leave at the Patent Office a "statutory declaration," stating whether or not the allegations contained in the application are correct; and, if they are incorrect, to what extent, and in what place the patented article or process is manufactured or carried on in the United Kingdom; and setting out in the event of the article or process not being manufactured or carried on in the United Kingdom to an adequate extent, the reasons why it is not so manufactured or carried on. The patentee must deliver copies of this evidence to the applicant, and furnish the Comptroller with evidence of delivery.

Certain rules are given for the exact form that this "statutory declaration" must take, and it must be made before a justice of the peace or a commissioner of oaths, or, if made outside the United Kingdom, before a British Minister, Consul, Vice-Consul, notary public, judge, or magistrate.

The applicant is now given fourteen days, "or such further time as the Comptroller may allow," to reply to this, in the form of a similar statutory declaration, and he must deliver copies to his adversary as before and furnish proof of delivery to the Comptroller. The Comptroller may ask for further evidence, in which case, presumably, the same process is continued. When the Patent Office has taken full cognisance of the evidence, the Comptroller will appoint a day for hearing the case, and will give the applicant and the patentee ten days' notice; and in the event of the Comptroller deciding to take evidence *viva voce* in lieu of or in addition to the evidence by declaration, or to allow any declarant to be cross-examined on his declaration, he may require the attendance of any declarant or other person, whose evidence he may consider desirable. If, as is probable, the applicant or patentee desires to attend the hearing, he has to signify his intention on "Patent Form 9" within five days, and has to pay a fee of £2. The Comptroller has the power to require that evidence be taken on oath, and he may award to any party such costs as he may consider reasonable, and direct by which party they are to be paid. This, it will be seen, may in itself occasion a heavy expense, far exceeding the comparatively small fees already mentioned, if several

Digitized by Google

witnesses are called, and if the hearing lasts a long time; and an additional cost will, of course, be the appeal to the High Court, which is almost bound to follow the Comptroller's decision, and in which both parties would, of course, be represented by counsel.

Those who have read the new Patents Act carelessly may think that they would be entitled to infringe an unrevoked patent that has not yet been worked in this country, and then put in a claim for the revocation of the patent as a counterclaim to any action for infringement that might be instituted. This is not the case, however. It is true that under Clause 32 of the Act, a defendant in an action for infringement, if entitled to present a petition to *the Court* for the revocation of the patent, may apply by way of counterclaim for its revocation, but in the case of revocation for not working in the United Kingdom, the petitioner is only entitled to apply to the *Comptroller* and not to the Court in the first instance, so that the clause does not apply here.

Returning now to Clause 27 in the Act itself, it will be seen that wide discretionary powers rest with the Comptroller with regard to the revocation of unworked patents. In defending his patent, the patentee has either to prove that the patented article is manufactured to an adequate extent in the United Kingdom or must give "satisfactory" reasons why it is not so manufactured. No indication is given in the Act what reasons are to be regarded as "satisfactory." A number of advertisements have appeared in various technical journals recently over the names of well-known patent agents offering patents for sale, or offering licences under them, and in a large number of instances the subject matter of the patent is described by title only without the name of the patentee or the scope of the patent being mentioned. It is certainly doubtful whether such announcements are likely to attract *bonâ fide* offers to buy the patent or take licences under it; and it is still less likely that the fact of the insertion of such a bald advertisement in one or perhaps two trade newspapers not having resulted in useful negotiations would be regarded as a satisfactory reason for the patent not having been worked in this country. Surely some greater effort on the part of the patentee would be required. If he is unable to find the funds to work the patent here himself, or is not himself in a position to find a market for his patented article sufficient to warrant its manufacture here, an honest endeavour to find a purchaser or licensee might conceivably protect the patent from revocation, or at any rate enable him to obtain an extension of time under the discretionary powers of the Comptroller. But unless he can prove that he has persistently advertised for a purchaser or licensee in all the leading papers devoted to the particular trade in question, and has supplemented this personally, by an active endeavour by other methods as well, to place the patent or to find means of manufacturing his patented article here, we cannot think that he would win his case. A perfunctory announcement of his willingness to part with his patent rights by licence or sale, made in an obscure way in the holiday months of the year, would, we think, rather act prejudicially to than assist a subsequent endeavour to answer an action for revocation under the new Act.

Passing from the letter of the law to the actual effect it is having at the present moment, it is satisfactory to note that the result of this clause in the Patents Act has already been the building of a number of works in this country for the manufacture of articles that have hitherto only been imported from abroad. The most important of these to the electrical industry will be the factories that will be devoted to the manufacture of metal filament lamps. The owners of the Auer and Just-Haneman patents (the General Electric Co.) are already manufacturing here at the Robertson lamp works, and we are waiting to hear that the owners of the tantalum lamp (Siemens Bros. Dynamo Works) have taken a similar step. A lamp, called the "Z" lamp, has also been manufactured tentatively at a works in Willesden, but, so far as we have been able to ascertain, no great progress has been made towards bringing a British-made Z lamp generally upon the market; but experiments in the manufacture of these new lamps must necessarily proceed slowly. The lamp made under the Kuzel colloid patents, and at present manufactured in Germany by the Pintsch Company, is to be made here, and we understand that a company or syndicate has been formed which has taken the "Imperial" works at Brimsdown, recently occupied by Messrs. Waters' shellac factory. Power for driving the works will be taken from the North Metropolitan Electric Power Supply Co. It has been announced that the employees will be drawn from the district, and this may account to some extent for the choice of the situation of the works, which is not very distant from the Ediswan works at Ponder's End.

Finally, metal filament lamps under the British Thomson-Houston patents, which have for the most part originated with the firm's parent company in America, are being made at Rugby, and the Sunbeam company at Gateshead are enlarging their works in order to make metal filament lamps under the Westinghouse patents.

Altogether, it will be seen that there is evidence of considerable activity in this direction, and doubtless one of the most interesting and useful features of the electrical exhibition to be held in Manchester next month will be the display of British-made metal filament lamps.

The "G.B." Surface-Contact System in London.—According to *The Morning Leader*, Mr. W. M. Mordey, President of the Institution of Electrical Engineers, has been retained to report upon the working of the "G.B." surface-contact system of traction in the Mile End Road. It is said that the London County Council have asked Mr. Mordey to report, and that he has been to Lincoln to investigate the working of the system there.

Obituary.—We regret to announce the death, at the age of 71, of M. E. Mascart, the eminent French physicist. He had been since 1878 director of the Central Meteorological Office in Paris, and was the author of several scientific treatises. To our readers he may be remembered as being the joint author with M. J. Joubert of the classical work, "Leçons sur l'Electricité et le Magnétisme. He was a member of the Institute, a professor at the Collège de France, and an honorary member of the Institution of Electrical Engineers.

Alleged Death from Electric Shock.—Whilst a smith's striker was working an electric welding machine at the works of Messrs. Dobson & Barlow, Bolton, he suddenly fell, and died soon afterwards. The doctor said there was no possibility of accounting for death except by electric shock. A fellow apprentice stated that when he got hold of an iron bar which the deceased was holding he received a shock. The jury returned a verdict of death from shock.

Next Year's British Association Meeting.—Reuter states that a committee has been formed in Winnipeg to arrange for the entertainment of the British Association there next year. Various Western Governments and cities have been requested to co-operate. The programme includes a trip through the West and one through the mountains to the Pacific coast. Transportation facilities are being arranged, and a number of distinguished guests from Canada and the United States will be invited. Provision will also be made for a limited number of ladies.

Electrically Propelled Ships.—According to the *Elektrotechnischer Anzeiger*, a company in Berlin is fitting a steamship which runs on the Oberhavel with a system of electric propulsion. The equipment consists of a suction gas plant consuming anthracite, a gas engine coupled to a direct-current generator, a battery of accumulators, and electric motors on the propelling shafts. It is estimated that the running costs will be less than those obtained with an ordinary steam engine equipment, on account of the saving in fuel. Two new ships with a similar equipment will also be added to the service next spring.

A NORWEGIAN SINGLE-PHASE RAILWAY

TRONDHJEM, or Drontheim, the well-known seaport on the east coast of Norway, from which large amounts of copper, timber, and fish are exported, is situated on the Trondjhem Fjord. At the extreme end of the southernmost arm of this fjord is the small town of Thamshavn, and the railway which we are about to describe, and which is the first electric railway in Norway, runs from this town along the bank of the river Orkla to Svorkmo, a point some twelve miles distant from Thamshavn. An extension of the railway to Loekken, where there are copper mines, is now being constructed. Loekken is sixteen miles distant from Thamshavn, and is 540 ft. above the sea level. In the year 1897, the company which owns the railway, the Chr. Salvesen & Chr. Thams's Communications Aktieselskab, of Thamshavn, applied for a concession to construct the railway, but this was not granted until

Fig. 1.—View of the Falls at Skjenaldfossen, with Power Station on the Left.

1904. The railway was opened by King Haakon on July 10th last.

At Thamshavn there is an extensive quay, up to which very large vessels can proceed, and there are special arrangements for delivering the copper ore, which is brought from the mines in Meldalen, direct from the railway trucks into the ships; the trucks are taken out to the end of a pier on an elevated track to where the ore-shoots are. A large depôt for storing the ore, and workshops in connection with the railway, are under construction.

Except in the stations, the line consists of single track of 3.28 ft. gauge, with a maximum gradient of 1.3 per cent., except for a short section close to Thamshavn, which has a gradient of 4 per cent. The sharpest curve is 820 ft. radius. The construction of the track has been carried out under the superintendence of a government engineer, as it is possible that the line may, at some future date, be connected with the government's railway system. The rails weigh 42 lbs. per yard, and are supported on fourteen sleepers per length of rail of 10 yards. The dimensions of the sleepers are 6.25 ft. by 8.7 in. by 4.4 in. All the bridges over which the railway passes are constructed of steel. The stations are connected by telephone, all circuits having metallic returns. There are four level-crossings and one tunnel.

The power supply for the railway is obtained from a

Fig. 2.—View from the Power Station, showing Dam and Pipe Line.

generating station at the Skjenaldfossen waterfalls, some five miles distant from Thamshavn. The dam and the commencement of the pipe line are illustrated in Fig. 2, and the falls themselves are to be seen in Fig. 1. The building on the left of this illustration is the power-station which is situated at the foot of the falls. The station was built and equipped by the company in 1905, and has since supplied light and power to Thamshavn and other towns in the district. The falls have a head of about 185 ft., and the average available power is 3,000 h.p. In the power-stations, the

Fig. 3.—Baardshaug Station with Passenger Train.

interior of which is shown in Fig. 4, there are five turbine generating sets, with a total capacity of 3,080 h.p., and they are all fitted with automatic regulating apparatus. The turbines run at 750 revs. per min., and are direct coupled to 545 K.V.A. three-phase generators. Current is generated at 1,000 volts and transformed up to 15,000 volts by means of oil and water-cooled transformers. The frequency is fifty cycles.

The 15,000-volt transmission-line goes direct to a station on the line called Baardshaug; here it divides,

Digitized by Google

one line going straight to the mining district near Loekken, the other alongside of the line to the converter-station at Thamshavn. This sub-station contains an oil transformer, which transforms down from 15,000 volts to 600 volts. Two three-phase motors, fed with current at this pressure, are direct-coupled to twenty-five cycle single-phase generators, which supply current

The rolling-stock consists of three 20-ton 160-h.p. locomotives for hauling goods and passenger trains, and one 80-h.p. motor-car for first-class passengers only. Each locomotive is equipped with four enclosed Westinghouse single-phase compensated-series commutator motors, connected two in series. The maximum speed of the locomotives is thirty-one miles per hour.

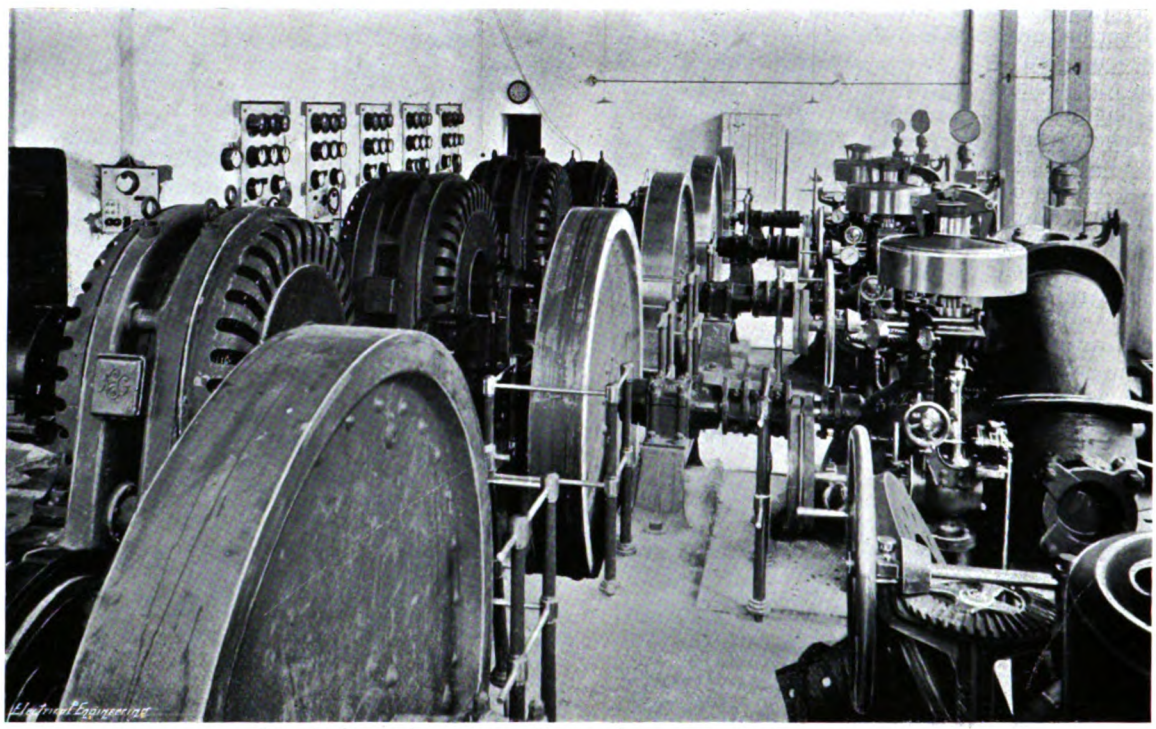

FIG. 4.—INTERIOR OF THE POWER STATION AT SKJENALDFOSSEN.

to the overhead contact line at a pressure of 6,600 volts. These motor-generator sets have a capacity of 250 kw. each at unity power factor, and are controlled by an automatic pressure-regulator. The substation contains, besides the transformers and motor-generators, the usual lightning-protection apparatus, switchgear, etc.

Current is collected from the contact line by means of a pantograph-bow operated by compressed air. One of these bows can be seen attached to the motor-car in Figs. 3 and 5. The equipment of locomotives and car also includes transformers for reducing the pressure from the contact line-pressure of 6,600 volts to the motor terminal-pressure, which is varied from 240 volts

FIG. 5.—TRAIN CONSISTING OF LOCOMOTIVE AND TWO TRAILERS AT BAARDSHAUG STATION.

The method of suspension can be gathered from an inspection of Figs. 3 and 5. A steel wire is supported on high-tension insulators, and from this wire the contact wire is suspended by means of short hangers and clip fastenings, on the single catenary principle. The contact wire has a section of 0.1 sq. in.; the rails form the return and are bonded.

at starting to 540 volts at full speed. Both locomotives and cars are fitted with Westinghouse compressed-air brakes, with the necessary complement of motor-driven air compressors, reservoirs, etc. Hand-operated brakes are also provided.

The electrical equipment of the motor-car consists of two 40-h.p. motors of the some pattern as those in-

Digitized by Google

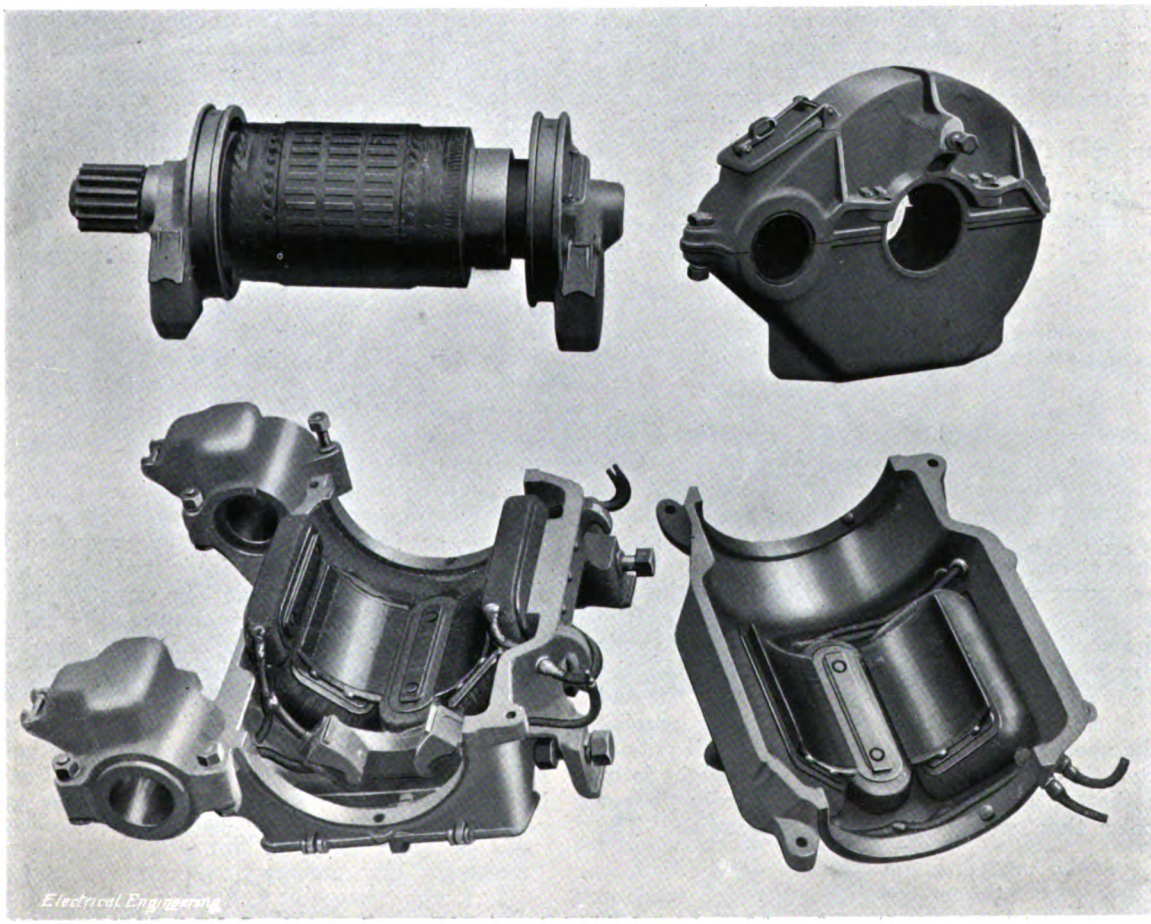
stalled in the locomotives, and the necessary transformer, switch-gear, and brake equipment. The other items of the rolling-stock are four passenger trailers, three goods waggons, and eighteen trucks for ore, ballast, etc. As previously mentioned, a transmission line to Loekken supplies power to the mines in Meldalen, where the air compressors, winding machinery, etc., are electrically driven. From Loekken another line, six miles long, goes to the Hoeidal mines, which are twenty-two miles from the power-station at the Skjenaldfossen falls.

The locomotives and the single motor-car were supplied by the Westinghouse Co., but the rest of the electrical work was carried out by the Elektrisk Bureau of Christiania. We are indebted to Chr. Salvesen and Chr. Thams's Communications Aktieselskab, of Thamshavn, for the particulars in this article, and for the photographs with which it is illustrated.

INTERPOLE TRACTION MOTORS

THE requirements of modern electric tramway practice are much more exacting than those of earlier years, partly on account of the more extended use of electric braking, and also from a general alteration in the conditions of service. With a view to meeting these more onerous conditions, Messrs. Dick, Kerr & Co. have developed a series of interpole motors, embodying a number of new points in design and construction and superior in many ways to the older type.

Such motors are particularly suitable for tramway systems where extensive use is made of electric braking, and in any circumstances where the duty is more than ordinarily heavy. We are informed that they are sparkless under practically all loads, cool in operation, and oil proof. Sparkless commutation, which is ensured by the addition of the interpoles, is particularly important when the motor is running as a generator for braking. Under these conditions, a certain amount of sparking has hitherto been considered unavoidable, and cases are not unknown of motors flashing over at the brushes when the controller is on the brake notches. The employment of interpoles also increases the overload capacity, and the wear of the commutator and brushes is reduced. Messrs. Dick, Kerr & Co. tell us that in some cases the motors will stand as much as 100 per cent. overload without injury. Further, the reduced wear of commutator and brushes, combined with improved methods of ventilation, results in the motor being very clean running, a fact which lessens still further the danger of flashing over, and also avoids other troubles well-known to the tramway manager. In general it may be said that these interpole motors will operate with complete satisfaction under conditions which would seriously embarrass motors of equal power but unprovided with interpoles.



Photograph of Various Parts of Dick, Kerr Interpole Traction Motors.

The motors are rated in the customary way, i.e., on the output, including gear losses, for one hour with a temperature rise in any part as measured by thermometer, not exceeding 75° C. (135° F.) above that of the surrounding atmosphere, the temperature of which does not exceed 25° C. (77° F.).

The field frame is made in the usual form of two bowl-shaped castings of soft steel of high permeability, thereby securing the smallest possible weight. The two halves are fitted together with a carefully machined joint to ensure a good magnetic circuit, and to make

Digitized by Google

the frame both watertight and dust-proof. The lower half of the frame is hinged to the upper half, thus permitting the lower field coils to be easily inspected and cleaned.

Each armature bearing box is contained in a separate solid casting independent of the motor frame altogether, being held in position in the main motor frame by means of a tongued and grooved joint, and firmly fixed by studs. The armature can, therefore, be lowered with the bottom half for inspection, or can be retained in position in the top half, as may be desired. It can further be removed from the main shell with its bearing boxes complete, if occasion requires it. Special attention is called to the fact that the bearing boxes for the armature are solid. This is a most valuable feature of the design, as it effectually prevents oil from the bearing creeping into the interior of the shell, thus making the motor practically oil-proof.

The main pole pieces are made up of laminated steel sheet punchings rivetted together, and are bolted to the inner surface of the frame. The pole pieces are interchangeable, and can readily be replaced in case of repair. For supporting the main field coils, two flat steel springs, each capable of exerting a pressure of about 400 lbs. are inserted between the field coil and the shell. The coils are held in place by the pole shoes themselves, and brass washers which cover the surface of the coil. As each coil is thus forced against the brass washer by the springs with a pressure of nearly 800 lbs., any shrinkage of the coil is automatically taken up, and the coils at all times held rigidly in position. Mechanical troubles in this portion of the motor should thus be entirely obviated.

The interpoles are of solid steel, situated symmetrically between the main poles and fixed in position by rivets. The interpole field coils are clamped in position by independent screws which are properly locked to prevent any movement. The ends of all field coils are finished off with strong bronze terminals for interconnection after they are assembled in the motor frame.

The armature core is built up in the usual way, with distance pieces to permit free circulation of air. Ventilation is also assisted by means of the fanning action of the connections between the armature coils and the commutator bars. These connections are made of thin flat copper strips, which, when the armature rotates, act as fan vanes, and draw a current of air right through the motor. The air enters through the opening on the top of the shell at the gear end, and is drawn towards the centre of the armature core passing through the end winding at the gear end, the armature core, the end winding at the commutator end, and finally passing out of the shell at the opposite end to which it enters. It is stated that this artificially-produced draught is so effective that it enables a motor to run fully 25 per cent. cooler than would be possible otherwise. The beneficial action of these fan vanes is independent of the direction of rotation.

The armature leads are carried straight to the commutator risers, so that the removal of the commutator is easy. All that is necessary to do, in order to remove the commutator, is to unsolder each conductor and bend it slightly upwards. The commutator can then be pulled off without any disturbance of the armature winding.

Particular attention has been paid to the bearings and the method of lubrication. As previously indicated, the armature bearing boxes themselves are solid castings, entirely independent of the main motor frame. They are made to gauge, and interchangeable, as are also the bearing brasses. A constant and efficient supply of oil to the armature bearings is secured by employing oil rings which the firm have found by actual practice to be superior to any other method of lubrication. The oil after use in the bearing is drained back to the reservoir by large drain channels, which have sufficient capacity to deal with the maximum amount of oil which can possibly be supplied to the bearings. The continuous flow of oil has a cooling action on the shaft, as well as acting as a lubricant. Special oil throwers are provided to deal with the small amount of oil which is not taken care of by the main drains, the oil from the throwers also being drained back to the oil chamber. After the bearings have been filled with oil they will run with safety for a considerable length of time without attention; it is even said to be quite safe to allow such bearings to run for a fortnight without oiling, although it is, of course, better practice to have a regular system of oiling once a week. Special chambers are provided below the oil reservoir, and any oil which is not returned to the main reservoir drains into these chambers. The bottom of each chamber can be closed by a cover, and when this opening is closed the motor can plough through almost any depth of water without getting flooded.

The axle bearings are also lubricated by means of oil, but in this case a wick arrangement is employed. These bearings will also run for a fortnight before requiring refilling. Arrangements are provided for allowing the wick to be quickly and easily withdrawn. Two helical springs acting on the wick-holder press the wick against the axle, two springs being provided to ensure that the lubrication is not interfered with, should one spring fail from any cause. The armature bearings are made of special anti-friction bronze, the axle bearings being also of bronze or malleable iron lined with best white metal, as may be desired.

The whole of the gearing is contained in a malleable iron case in two halves, which is designed to withstand heavy vibration, and is supported at three points. All bolts are of the same size, and are locked from turning by special lugs cast on the frame and gear case. The nuts are locked by spring washers.

MESSRS. J. H. HOLMES AND CO.'S WORKS

IT is to be hoped that Messrs. J. H. Holmes & Co., of Newcastle-upon-Tyne, will not misunderstand us when we say that their works are distinctly deceptive. As viewed from Portland Road, where their main entrance is situated, a very modest conception of their size is obtained—an impression which is entirely contradicted by a tour through the various shops, employing upwards of 540 men.

In 1883, when the works were established by Mr. W. H. Holmes and three of his sons for the purpose of installing electric light in private houses, factories, workshops, steamships, and the like, the staff consisted of one man and a boy, and such work as the temporary lighting of bazaars, flower shows, and balls, and the illumination after dark of skating ponds and football fields, was very acceptable. In thost days electricity was in the nature of a novelty, as was evidenced in 1884, when their present Majesties, then Prince and Princess of Wales, visited Newcastle. On that occasion Messrs. Holmes provided portable steam engines and dynamos, and fitted various prominent places in the town, such as the steeple of St. Nicholas Cathedral, with powerful arc lights, which were the most attractive items in the whole scheme of public illumination. This firm's pioneer work did not a little to popularise electric light in the North.

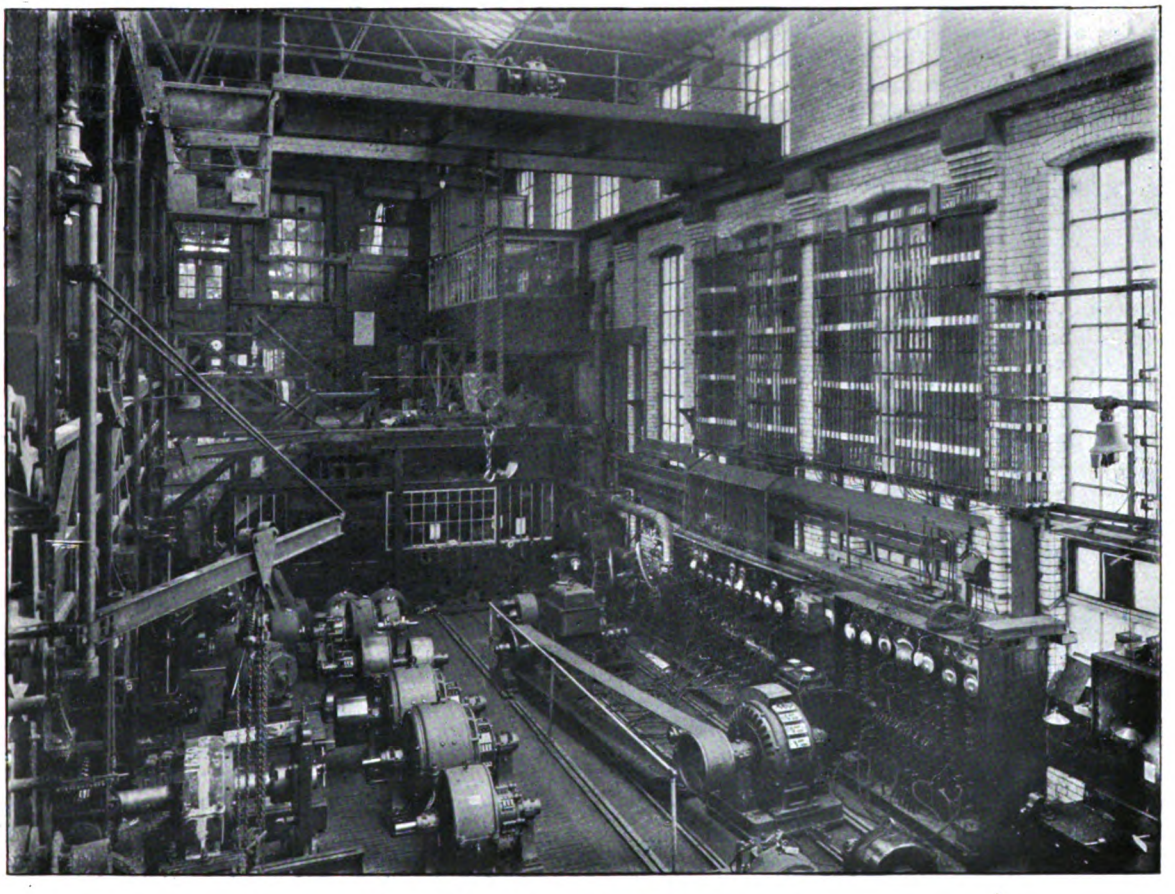
Digitized by Google

Their first workshop, for the manufacture of electrical supplies, was opened in Stoddart Street, Shieldfield, and was occupied until 1887, when the central portion of their present premises was built. At that time it was hardly possible to obtain items such as switches, fuses, ceiling roses, and lamp holders of good quality in the open market. Early in the year of 1884, Mr. J. H. Holmes invented and patented the loose handle or quick-break switch which, in various modifications, is almost universally used throughout the whole world. At one time no fewer than thirteen firms were under licence to make these switches under the patent, and at the 1885 Inventions Exhibition in London, the firm obtained a bronze medal for their exhibit of these switches. Although the making of dynamos and motors was commenced in 1884, the Number One "Castle" dynamo made at that time is still at work in Ireland, and furnishes a standing—or running—defiance to depreciation and "obsolescence."

Other inventions rapidly followed. In 1889, at the request of the late Mr. W. Langdon, the electrical engineer of the Midland Railway Company, Mr. J. H. Holmes, designed and patented a constant potential dynamo capable of being driven at variable speeds in either direction from one of the axles of the guards' van, and this was applied, not only to the Midland, but also to railways in Germany, France, and Russia. In the same year the Suez Canal Company allowed the passage by night through the canal of any vessel carrying an electric light projector at the bow, having a certain range of projection. Mr. Holmes went to Egypt, spent some time there studying the requirement of the officials, and on his return designed suitable projector apparatus, very many of which, together with their portable generating sets, have been manufactured for canal and river traffic. In 1896 the firm acquired the British rights in the Lundell patent, while in 1898 they introduced the well-known "Holmes-Clatworthy" system for driving web printing presses for the production of newspapers.

With the extension of business involved in these patents, together with the contracting work of the firm in fitting up country houses with electric light and generating plant driven by steam, gas, or oil engines, the manufacture of "Castle," drum, Lundell, and other machines, the fitting up of upwards of 900 steamships ranging from Royal yachts to ocean tramps with electric light, and the electric lighting and power equipment of mills and factories at home and abroad, it is no wonder that the floor area of their works has enlarged from 240 square yards in 1885, to 10,684 square yards in 1908.

The works comprise two main buildings, in which the principal operations of manufacturing, assembling, erecting, testing, packing, and despatching are carried out, while in separate buildings are the foundry, pattern shop, electrical instrument shop, and stores. The main buildings are divided into departments for machining and drilling the castings and forgings, winding armature, and field coils, building commutators and cores, and manufacturing smaller work, such as switchboards, switches, projectors, fuses, gear wheels, and fittings. In the machine shop are found a large number of modern tools, including automatic grinding machines, large turret lathes, a 100-ton hydraulic press, and the usual complement of a large engineering shop. Electric cranes serve the shop, while the whole of the plant is electrically driven, the larger machines and those of smaller size requiring quick speed variation being fitted with individual motors. An interesting example is a Niles vertical boring mill fitted with a motor having a double-wound armature, giving a cutting speed on the tool up to 80 feet per minute. In this shop, steel castings for magnets are regularly turned and bored at cutting speeds of 60 to 80 feet per minute, and hard steel spindles are roughed out at 50 to 100 feet per



Portion of the Erecting and Testing Shop.

Digitized by Google

minute with cuts up to ¼ in., afterwards being ground to a fine finish to half a thousandth of an inch accuracy by Browne & Sharp automatic grinders. These speeds and feeds are from 300 to 500 per cent. better than those considered good practice a few years ago, and indicate the advance rendered possible by self-hardening steel and rigid machine tools. There is in this shop a special tool department for grinding and storing tools, where gauges, micrometers, &c., are kept. The whole of the machining is carried out to limit gauges, while jigs and templates are extensively used for drilling and boring.

Erection and testing is carried on in a large building adjoining and at right angles to the machine shop, and divided into six sections for tool making, repetition work, erection of dynamos and motors up to 60 b.h.p., large armature building, erection of machines up to 750 b.h.p., and testing. The tool making shop is equipped with the latest machinery for quickly meeting the requirements of the other departments, while the repetition work section turns out all the brass and iron screws, bolts, nuts, and terminals required in the firm's manufactures. One gallery is set aside for the erection of the smaller machines and the fitting of reduction gears to motors, being served with an overhead travelling crane for rapid handling. The erecting and testing of large machines is, however, carried on in the main bay, where several electrically driven tools, notably a large radial drilling machine, are located. This bay is served by a powerful three-motor travelling crane and several jib cranes. The principal testing bed is made to accommodate direct-coupled steam plants, arrangements being made to conduct tests simultaneously at different steam pressures on the various sets. Large motors are also included in the equipment for testing dynamos without engines, and there is a large testing switchboard, complete with all recording and measuring electrical instruments. At the time of our visit, 700 to 800 dynamos and motors were passing through the shops, and among the interesting machines under erection or on the test bed was a motor-alternator for the Birmingham University, a booster for Brisbane, Western Australia, several reversible booster sets for "floating" batteries, a 30 h.p. vertical motor for shaft sinking, running at the high speed of 2,400 r.p.m., which was doing its work with the greatest facility on the test bed, and several ship lighting plants. The illustration on p. 359 shows a portion of the erecting and testing shop. The testing bed and switchboards are at the right-hand side with the offices of the testing staff in the background. In this illustration, the machine under test is a three-phase generator.

Reference should here be made to the generating station which supplies the current for lighting the works, driving the machines, and conducting the tests. At the present time steam is supplied by two Lancashire boilers at 180 lbs. pressure to four high-speed direct-coupled sets aggregating 330 b.h.p., but the steam plant is being replaced by three-phase motors which will drive the existing continuous current generators. Energy for this purpose is obtained from the Newcastle-upon-Tyne Electric Supply Co., Ltd., a static sub-station having been built on the works to transform from 6,000 to 440 volts. All the motors driving the line shafting in the shops are now three-phase, but for machines where a wide speed range is desirable and are individually driven, and in the case of some of the cranes operated by series motors, continuous current has been retained. The generating station board is arranged so that two, three, or four dynamos can be connected in parallel or series for the purpose of obtaining any desired pressure for testing; motor generators with a range of 115 to 600 volts provide the current for testing medium-sized motors, while high pressure testing up to 2,000 volts is dealt with by an alternator.

The starting switches for controlling the shafting motors are also placed in the generating station so that the engineer in charge can simultaneously start all the shaft-driven machinery in the works. There are over 130 motors installed in the whole works for electric driving, &c., ranging in size from 1/6 h.p. to 100 h.p. The total aggregate horse-power amounts to 780, and the average daily load for power purposes, excluding testing, equals about 80 h.p. The power station deals with approximately 250,000 b.o.t. units per annum.

Above the heavy machine shop, which we have already described, are three floors, devoted respectively to switchboard erecting, brass finishing, and commutator building, the manufacture of switches, and the storage of raw and finished material. On the first floor the manufacture of ships' fittings, brush holders, and projectors is also carried on, together with the assembling of large motor starting switches, and the controllers, and the erection of switchboards. Some of these range up to 50 ft. in length, and a very fine example was passing through at the time of our visit. One of the features on this board was a switch with an internal toggle joint, and an abutment release, while on another section was a two-way throw-over main switch, whose "off" position was secured by the engagement of an ordinary cycle "ball" into a recess in the hinge of the switch blade.

On the second floor, switches of all sizes from 25 amperes and upwards were being made, many of them being the firm's "Holmes-Page" type, which, either open or fitted in gas and watertight cast-iron boxes, together with similarly-protected fuses or with asbestos-tube fuses, are too well known to need further description. Motor-starting switches, reverse-current circuit breakers, mining panels, &c., were also under manufacture, and we saw a demonstration of quick-acting circuit-breaking, which operated down to 3 per cent. reverse current—considerably below practical requirements. Lift control switches were also on view, and an electrically-controlled steering gear for the Italian Navy was also interesting. A rather curious device for mine motor starters was an arrangement of a double ratchet, engaging on the handle of an iron-clad starter, so that the handle could not be swept directly forward, but had to be "joggled" along its path, giving the motor time to start up.

The store on the top floor is served by two electric lifts, one being open to all departments below, the other communicating direct with the goods receipt and despatch department, situated in an extension of the main building. The foundry contains little of exceptional interest beyond a motor-driven magnetic separator to extract iron and steel particles from scrap brass and copper before the latter is run into ingots. The wood-working department is also most efficiently equipped.

Special mention must be made of the new five-storied building which is now devoted to small motor manufacture. The top floor, owing to the steep gradient of the works site, is approximately on a level with the bottom floor of the older building, and is connected by a bridge carrying a narrow-gauge railway. The erecting floor on the top storey is so arranged as to allow the work to "follow on" in sequence, rails running the whole length of the shop past long rows of low erecting benches, and into the testing shop beyond. In the erecting shop overhead runways above the benches give quick handling of motor parts, while machinery for turning and grinding up commutators on the finished armatures is also fitted in the erecting shop.

The testing department is equipped with four testing tables and switchboards, each table having its own complete motor generator set for giving any desired voltage. By this means, four motors can be tested simultaneously, each at a different voltage. Power de-

Digitized by Google

veloped by any motor under test is used for driving a dynamo, the current generated by the latter being used to assist in driving the motor generator which is supplying the motor under test. This utilisation of the Hopkinson method of testing necessitates only a small proportion of the load being taken from the power station, sufficient only, in fact, to compensate for the frictional and electrical losses in the testing plant.

All motors finished off for stock are kept above the testing and painting shops, an electric lift being provided between the two floors. Armature cores are stacked up near the central hoist, and overhead runways are provided for conveying them to the winding benches, and subsequently to the binding lathes. The magnet coil-winding machines, which are electrically driven, are arranged along one side of the shop, and include several automatic and semi-automatic machines for laying the wire on evenly. On the other side are the machines for taping the armature coils, special tools to shape them for core slots, and an air pressure blower, with a complete installation of pipes for supplying air blast to gas stoves for brazing, soldering, &c. There is also a special transformer for testing the finished armature coils before assembling them on the cores.

A large fireproof room at one end of this floor is devoted to drying, dipping, and impregnating all armature and magnet coils with insulating varnish by the vacuum process. A large horizontal iron cylinder is employed, fitted with a number of shelves and trays to accommodate coils, armatures, &c., the large armatures being placed on the bottom. When the removable door at one end has been securely fastened, the inside of the cylinder is heated to a temperature of about 150° F. by means of a coil of steam pipes. The air is then exhausted by an electrically-driven air pump, and a vacuum of 29 in. to 30 in. obtained, dependent upon atmospheric conditions. It will thus be seen that every particle of moisture is drawn out or evaporated, and the armatures and coils rendered perfectly dry. After remaining in this vacuum chamber for some hours, the articles are taken out and plunged into a tank of insulating varnish, subsequently going into the vacuum chamber again to dry, after which treatment they are practically waterproof.

Further protective measures are taken with field magnet coils and small wire-wound armatures, having a great many closely-wound layers of wire. These are also passed through smaller vacuum chambers, which are connected with the varnish tank. After the air has been exhausted a tap is opened, and as the top of the varnish tank is exposed to air, the atmospheric pressure forces the varnish into the vacuum, filling it up under a pressure of about 10 lb. per square inch. It will be readily understood that this process causes the varnish to enter every space, however small, and covers the inside wires as thoroughly as the outer layers. The surplus varnish is allowed to return to the tank below the floor by gravity, the armatures or coils being subsequently dried in the bigger chamber, after which they are finished off and allotted to their respective jobs.

The resistance frame and sheet metal working department and core building shop are on the floor below. A speciality is made of cast-iron grid resistances, stiffened by Holmes patent asbestos and metal strips, and in connection with the grinding of the contact surfaces of the grids an interesting attachment to the grinder is used, consisting of a magnet surface plate or holder, formed of interlaced fingers having opposite polarity when energised by a small magnetising current. By this means the grids are held in position during the process of grinding, being easily removed from the holder when the current is switched off. The core shop is equipped with powerful blanking presses, automatic notching machines, circle cutting machines, and hydraulic presses for assembling cores. In this shop all pole-piece stampings are made and built up together with the three-phase stators and rotors.

It will be evident from the above description that a very great amount of care and experience has been directed towards the equipment of these works, and while we must congratulate Messrs. J. H. Holmes & Co. on the result, we must put on record our appreciation of their courtesy in giving us facilities for the preparation of this article.

A NEW FIELD TELEPHONE SET

THE International Electric Co. have sent us an interesting little pamphlet, which is well illustrated, dealing with the subject of field telephony in general, and the "Medhurst" field telephone in particular. This instrument, which weighs only a little over four pounds, consists of a transmitter, receiver, Morse telegraph key, switch, buzzer, dry cells, and a condenser, which are all contained in a leather case.

The transmitter is of the interchangeable sealed capsule pattern, in which damage to the carbon of the microphone is

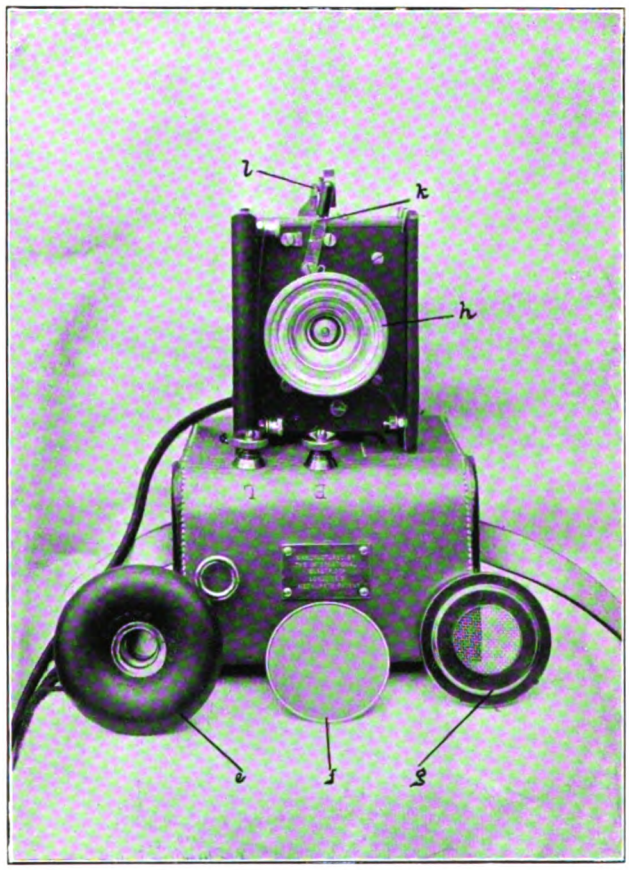


Fig. 1.—Field Telephone with Transmitter Capsule Detached.

simply repaired by inserting a new capsule. In Fig. 1 the capsule is shown at *f*; it is clamped into the carrier, *h*, by the ring, *g*. No loose wire connections are required, as the contact points meet one another as soon as the capsule is placed in position, and the ring is screwed home. We are informed that the capsule is absolutely watertight, and that it can be immersed in water for 24 hours without impairing the action of the transmitter.

The receiver is of the double-pole watch pattern, and there is a screw to adjust the diaphragm to synchronise with the note of the buzzer, so that it can be used as a receiver for Morse signals when the telephone cannot be employed. The key, *l* (Figs. 1 and 2), is employed for transmitting the signals. A switch, *k* connects up the receiver for this purpose, and a pad, *e* (Fig. 2), can be provided for fitting over the receiver in order to keep out extraneous noises from the ear.

The buzzer serves equally for ringing-up, for these signals, and as the induction coil for the microphone circuit; it has a primary and secondary winding with resistances of one ohm and 250 ohms respectively. Battery power is supplied by two

Digitized by Google

Obach cells, *q*. The condenser is made on the Mansbridge principle.

Fig. 3 shows a field exchange for six lines. The large receiver at the top is made use of for calling up the exchange by means of a buzzer call, and a pre-arranged code of signals indicates from which station the call emanates. The operator

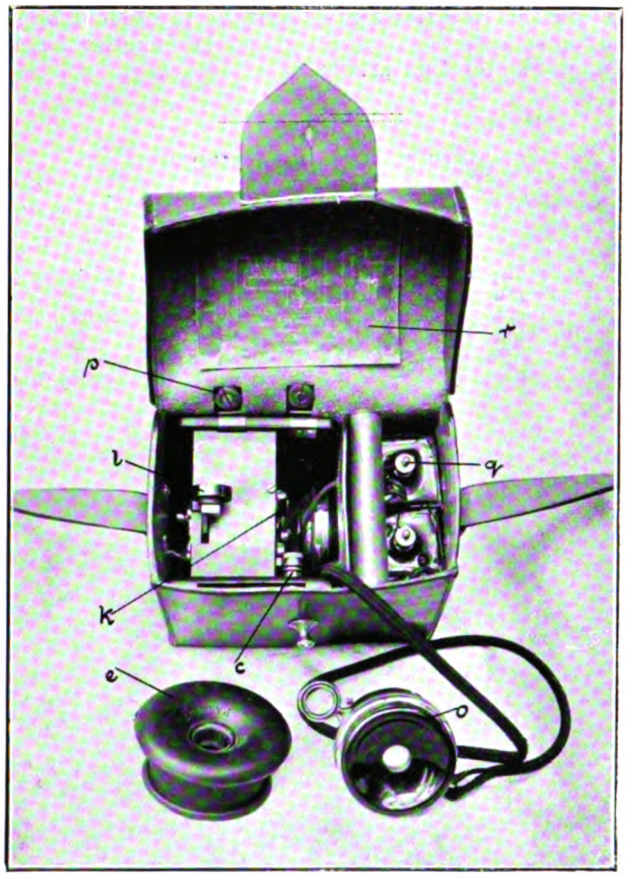

FIG. 2.—INSTRUMENT READY FOR USE FOR MORSE SIGNALS.

withdraws the corresponding plug from the bottom row of holes and inserts it in the hole corresponding to this station. Having ascertained the number of the wanted station, he

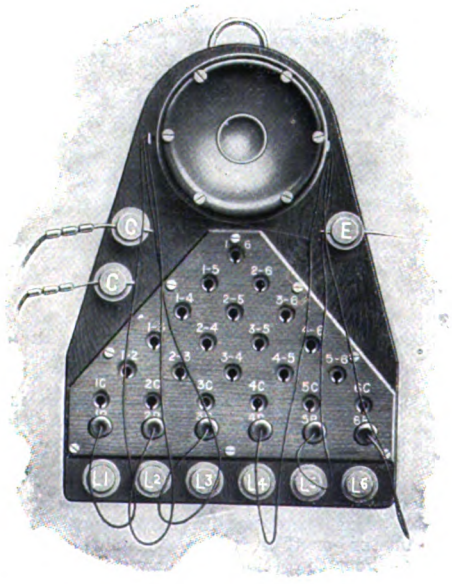

FIG. 3.—SIX-LINE FIELD EXCHANGE BOARD.

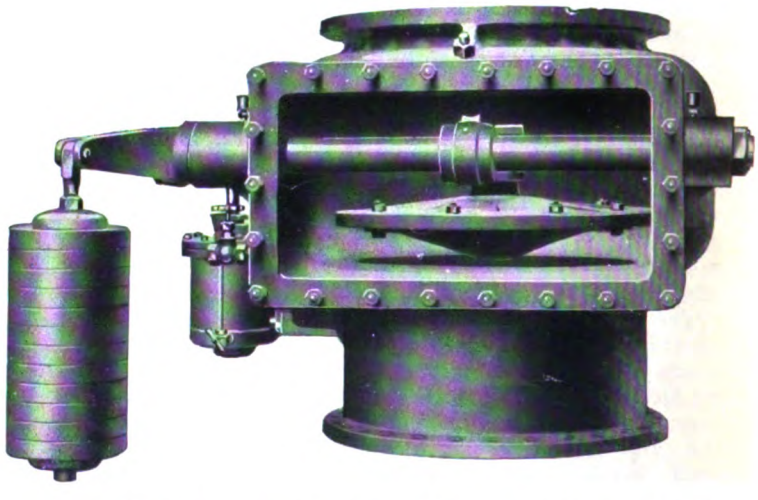
removes the plug and inserts it in the hole marked with the two numbers that are to be connected, the board being arranged on the "pyramid" principle.

CATALOGUES AND PAMPHLETS RECEIVED

ARC LAMPS.—A new price list from the Brockie-Pell Arc Lamp Co. contains full particulars of the well-known Brockie-Pell open, enclosed, miniature, and flame arc lamps. The direct-current miniature enclosed lamp takes only from 2½ to 3½ amperes, and burns for over 50 hours; the alternating-current lamp burns for about 40 hours. Both types have an overall length of only 16 in. The flame arc lamps are made on the same principle as the firm's open type arc lamps, and can be used with white or yellow flame carbons. These lamps burn for from 8 to 32 hours, according to the type, without recarboning. Globes, spare parts, and carbons are also included in this list.

TECHNICAL EDUCATION.—We have received from the Hackney Institute a syllabus of the classes to be held during the session 1908-9. These include classes in engineering and general science which are held at the Hackney Technical Institute, and practical trade classes which are held at the Sir John Cass' Hackney Institute. Time-tables and full details of the lectures and laboratory work are included in the syllabus, as well as particulars of the fees. The syllabus is illustrated with excellent photographs of the various laboratories and workshops.

AUTOMATIC EXHAUST RELIEF VALVES.—We have received from Messrs. Babcock & Wilcox, Ltd., a leaflet describing their automatic exhaust relief valves, which are designed for use with condensing engines, and act as safety devices in automatically relieving pressure in the condenser by by-passing the exhaust steam to the atmosphere. The relief valve is held hard down on its seating as long as a vacuum is maintained in the condenser, but any rise of pressure, due to the failure of the air or circulating pumps, lifts the valve and allows the steam to escape freely, thereby preventing the serious damage that might result from the sudden slowing down of an engine due to an accumulation of back pressure. The valve recloses automatically as soon as the condenser has regained its vacuum. If one condenser is used for several engines, only one automatic relief valve is required; but if each engine has its own independent condensing plant separate valves are needed. It is usually more convenient to place the valve within reach of the ground, and near the bottom of the uptake pipe to the atmosphere, and in this case the vertical pattern, shown in the illustration below, would be used. To suit varying piping arrangements, it is, however, sometimes convenient to use a valve of either the horizontal, inverted, or angle pattern, all of which work on the same principle as the vertical type. The body is of cast iron fitted with a renewable seating. The valve, also of cast iron, has a white metal seating which is cast into a dovetailed groove. This arrangement provides an air-tight joint, and prevents the valve adhering to its seat. The wear is all taken on the soft metal facing, which can be easily trued up or entirely replaced if necessary. The valve is balanced by an adjustable weight on a lever keyed to a spindle, which is carried in bearings bushed with gun-metal. To prevent hammering, due to the intermittent action of the exhaust steam, and to ensure the smooth action of the valve, a small piston, working in a dashpot of oil, is attached to the other end of the counter-balance lever. In the valve body an opening is



provided large enough to permit the removal of the valve for examination without disturbing any of the connecting pipes. A filling and a drain cock are furnished where a water seal is required, but this is not necessary except under special circumstances. A locking device is also fitted for holding the valve permanently off its seating when the exhaust steam has to be passed to the atmosphere for lengthened periods. These valves can be obtained in all sizes from 6-in. to 30-in. bore.

Digitized by Google

ELECTRIC SIGNS.—We have received from Simplex Conduits, Ltd., a leaflet describing their new patterns of fixed and moving signs. The signs can be obtained either for night work only, or by the addition of a special glass, for day work also. One single 16-c.p. lamp is said to be ample for most sizes, but to obtain a particularly brilliant effect a 25-c.p. lamp is used in the case of the largest size of 24-in. diameter. Lamps with a special shape bulb must be used with these signs. The signs with varying colour effects are operated by small electric motors.

IRONCLAD SWITCHES.—An artistically got up catalogue is to hand from Messrs. Parmiter, Hope & Sugden, of Manchester. This gives full information with regard to the firm's standard switchgear, which includes the well-known Ajax motor-starting switches, knife switches, ironclad switches, fuses, &c. To comply with the latest regulations, the handles of the latest types of the ironclad switches are interlocked with the cover, so that the latter cannot be opened until the switch is in the full off position, and, further, the switch cannot be put on until the cover is entirely closed. The electrical contacts are of phosphor bronze, and the cases are watertight, rubber packing being fitted round the lids. A new tandem switch is described; the special feature is the employment of adjustable coupling pieces, by means of which the two poles can be fixed to break together, and any extra lengths due to wear and tear or warping of the coupling bars taken up. Distribution fuse boards with spring clip fuses, in teak and cast-iron cases, are described, as well as the Ajax open, semi-enclosed, and totally enclosed motor switches. Particulars are also given of a new pattern of three-pole ironclad switch and fuse box, which will shortly be put on the market. A separate lid is provided for both the switch and the fuse box, and these are, if required, so interlocked that they cannot be opened at the same time, and neither of them opened until the switch is in the off position. It may be mentioned that in this pattern, as in most of the latest patterns, the switch handle is at the side. The cover need hus have no slit, and the hand of the operator cannot be burnt by any arc which may be formed. This arrangement with the handle at the side is one which has been strongly recommended by Mr. G. S. Ram, H.M. Electrical Inspector of Factories.

LAMPS AND FITTINGS.—We have received from the Linolite Company two or three leaflets relating to their "Tubolite" lamps and fittings. One of these gives particulars of the standard sizes of these fittings, which are constructed to take from one to ten lamps. The standard "Tubolite" lamp is 12 c.p., and can be obtained for pressures varying from 100 to 125 volts. For pressures above 200 volts, two lamps are connected in series. Another leaflet describes the chain-sling method of suspension, which is recommended for most cases where the fitting has to be horizontal. It can be instantly set to any angle, and is easily removed for dusting. Two patterns of desk or table stands for "Tubolite" lamps are illustrated in the same leaflet. The firm announces a reduction in price of the standard fittings, and states further that they hope soon to be able to put on the market a metal filament "Tubolite" lamp of standard dimension and 1·5 watts per candle efficiency.

METAL FILAMENT LAMPS.—A leaflet is to hand from the International Electric Co., in which is described their "Orieco" metal filament lamp; this is now made for voltages up to 250. The various sizes of lamps are listed as follows:—200 to 250 volts, 50 c.p.; 70 to 125 volts, 32 to 50 c.p.; 40 to 50 volts, 25 c.p.; and 25 to 30 volts, 8, 16, or 20 c.p. A pattern with spherical bulb is listed at 200 to 250 volts, 50 or 100 c.p.; and 70 to 130 volts, 25, 32, 50, or 100 c.p. The consumption of these lamps is given as 1·25 watts per British candle-power. Particulars of the "Orieco" accumulator lamps and other low voltage, low candle-power lamps are also given. These lamps can be used on continuous- or alternating-current circuits, and are now made to burn safely in any position. It is further stated that the high efficiency is maintained throughout the whole life of the lamp.

PEAR SWITCHES.—We have referred in recent issues to leaflets issued by Messrs. A. P. Lundberg & Sons, relating to wall-plugs and ceiling roses. A new leaflet describing their various patterns of "See-saw" and tumbler pear switches, has been sent us. The former can be obtained as a two-way switch for two-way and intermediate wiring purposes, or as a single-way switch. The bases of these switches are made of porcelain, and the brass sliding bar actuating the contact arm in both types is insulated from current-carrying parts. Several patterns of tumbler switches in pendant form are listed, as well as an improved pattern of the well-known "Bowspring" pear switch. "See-saw" switches for surface fitting and lever switches for use in the bases of portable lamp stands are also included in the list. Two patterns of door switches for laboratory lighting are described and illustrated, and a contact switch so constructed that the circuit is broken when the plunger is pushed home is mentioned. This type is employed for the lighting of strong rooms and cupboards, *i.e.*, where light is only required when the door is open.

RESISTANCE ELEMENTS FOR ELECTRIC HEATING APPARATUS.—A leaflet from G. Schniewindt, of Neuenrade, Westphalia, Germany, gives dimensions, costs, and other particulars of resistance elements which consist of fine resistance wire woven together with asbestos string. The nets are woven non-inductively. These compact and light heating nets are particularly suitable for light semi-portable electric heating apparatus of all classes. They can be obtained alone or fitted in iron frames insulated with vulcanite tubing. The standard unit measures six inches square, and consumes 250 watts. The diameter of the wire is varied according to the pressure. The large heating frames consume from 500 to 3,000 watts.

ELECTRICALLY-DRIVEN ROLLING MILLS AT SANDVIKEN, SWEDEN

THE methods which have been used hitherto for equalising the demand on the generating plant and dealing with the serious peaks which exist in the load curve of such installations as electrically-driven rolling mills, in cases where the supply is alternating and batteries are employed, have usually depended on one of two principles. The voltage of the continuous-current side of the motor-generator set is sometimes controlled by the current in the alternating supply circuit, either by a relay controlling the field rheostat of the continuous-current machine of the set, or by the employment of a small rotary converter fed by a series transformer in the main supply circuit to supply the excitation. These methods are open to objection where there is much variation in the power factor of the circuit, as the regulation is not then sufficiently close. In order to obviate this disadvantage, the Oerlikon Company have developed a modified system of control, in which the regulation is effected not only by the strength of the current in the alternating circuit, but by the actual power absorbed.

An installation of this kind has been carried out by the company at the rolling mills at Sandviken, in Sweden, for a maximum power of about 600 kw. This mill is supplied from a generating station at Näs, about 35 miles distant, over a three-phase 18,000-volt transmission line. Step-down transformers are used to reduce the voltage at the works to 520 volts. The various motors are arranged on two separate circuits. On one of these are placed those on which the load is very variable, including about 50 small machines varying from 5 to 30 h.p., and the following rolling-mill motors: one of 600 h.p., one of 500 h.p., one of 300 h.p., two of 225 h.p., and one of 140 h.p. On the other circuit are placed about 60 motors, varying from 50 to 100 h.p., the load of which is nearly constant. All these motors are three-phase. The sudden variations of power in the first circuit amount sometimes to 500 or 600 kw., and a maximum load of 1,570 kw. is occasionally required for short periods.

The equalising plant to be described is for the purpose of dealing with these peaks. By its use not only is it possible to connect more three-phase motors to the circuit than could be done otherwise, but also to maintain a supply to a certain number of continuous-current motors employed for cranes, &c., and a part of the lighting from the continuous-current side of the set. In the event, too, of an interruption in the three-phase supply, the motor-generator set can continue to supply either continuous current at 440 or 220 volts, or alternating current at 520 volts or 220 volts three-phase by drawing on the battery.

The main motor-generator set consists of three machines coupled in line and mounted on one bedplate. The machine in the centre is a synchronous three-phase alternator wound for 520 volts 50 cycles,

Digitized by Google

which can act either as a motor giving from 750 to 900 h.p., or as a generator with a normal output of 550 k.v.a. at a power factor of 0·8. The larger of the continuous-current machines can be used as a generator giving 1,100 to 1,400 amperes at 460 volts or a 600 h.p. motor. The third machine is a continuous-current booster, and has a maximum output of 1,400 amperes at 120 volts. The larger continuous-current machine is provided with three slip-rings connected to a 40 kw. three-phase transformer for supplying the existing three-wire 220-volt lighting system. Both continuous-current machines have commutating poles.

Another motor-generator is provided for supplying the excitation to the main set and at the same time regulating the voltage. This set consists of three machines. The driving motor is rated at 25 to 30 b.h.p. on a 520-volt three-phase circuit at 970 r.p.m., and is of the slip-ring induction type, with brush lifting arrangement. The exciter itself is a shunt-wound dynamo for 18 kw. at 110 volts, and the third machine is a 2 kw. regulating dynamo which supplies the excitation of the booster. The 18 kw. machine supplies the excitation both of the continuous-current generator and of the synchronous machine of the main set, as well as of the regulating machine. This last is provided with two opposed field windings, which are arranged to predominate according as the booster voltage is to be added to or subtracted from that of the battery.

12. Wattmeter Relay.
13. Exciter Bus Bars.
14. Paralleling Switch for Battery.
15. Booster cutting-in Switch.

The battery has a capacity of 1,406 ampere hours, and a maximum discharge rate of 850 amperes. It consists of 228 cells, and is divided into two parts, each provided with cell switch for the last eight cells, so that it can be used when required on the 220-volt circuit with the two halves in parallel. The system has been guaranteed to limit the fluctuations of load on the central station to 75 kw. in either direction, with variations of load up to 600 kw. and an average load of 1,570 kw.

A diagram of connections is given above. The regulation of the voltage of the small machine which excites the booster is effected by a wattmeter relay in the main three-phase feeding circuit. This relay actuates the regulating rheostat. The arrangement of the connections to the three-phase continuous and excitation is clearly shown. The continuous current generator of the large motor-generator set is provided with slip rings for connection to a three-phase static balancer or compensator.

When the power which is being absorbed is exactly equivalent to that for which the wattmeter relay is set, the position of the rheostat-arm is such that the voltage of the generator and the booster is exactly equal to that of the battery. If the load increases, the booster adds its voltage to the battery and allows it to discharge, and, on the contrary, if the load is below the mean the battery is charged. The regulator itself is of the well-known Thury pattern, driven by a small continuous-current 110-volt motor. A special arrangement is adopted to ensure that abnormal conditions of load shall not produce charge or discharge currents higher than a certain value. This consists of two solenoids which come into action when the current reaches the predetermined maximum, and oppose the action of the relay, so that further movement of the regulating switch is prevented. These solenoids are put in action by a separate relay (not shown in the diagram of connections) connected in shunt to the commutating pole-windings of the continuous current-generator through which the current to or from the battery passes. Another special device is provided to prevent the possibility of long continued overloads causing the battery to discharge to a greater extent than is desirable. This consists of a relay which inserts a resistance in the field circuit of the regulating machine as soon as the battery voltage falls to a certain limit, and thus prevents further discharge. As soon as the battery has received a certain amount of charge, and its voltage is thereby raised, this resistance is cut out of circuit again. A signal lamp is provided to show when this device comes into action. There is also a certain amount of hand regulation possible for giving the battery extra charging if required and avoiding overcharging, which might occur in special circumstances.

The fact that the power factor of the load has been found to vary from about 0·57 to 0·86 shows the desirability of a system in which the regulation is effected in accordance with the true watts passing and not merely the current. The efficiency of the converting sets when charging the battery at full current is 86·4 per cent., and the efficiency of the system when the battery is discharging at full current works out at 85·8 per cent, so that assuming a battery efficiency of 85 per cent. the overall full-load efficiency of the whole process of storage and subsequently drawing out energy is 63·15 per cent. The average overall efficiency of the whole system is, of course, much higher than this, as a large part of the energy does not pass through the battery at all. Actual records of the loads taken by the motors and drawn from the generating station show a remarkable degree of regularity in the latter, and even better results are anticipated when the generators are more fully loaded, as the governors of the water turbines will then be able to work within finer limits than at the present time, when the sets are only working at about two-thirds of their full rated load.

The switchboard consists of eleven panels, upon which are mounted the various starters, regulators, main switches, instruments, &c., which are required for the machines described above, each machine having its own panel. Three panels relate to the battery, and on these are mounted the overload circuit-breakers in the circuit from the motor-generator and the battery and various instruments, including charge and discharge meters. The synchronous machine is provided with an overload circuit-breaker actuated by a time-limit relay. The connections have already been indicated in the diagram. It will be seen that the voltage

Digitized by Google

of the continuous-current bars is independent of that of the booster, and corresponds only to the voltage of the generator, which can be kept very constant, so that lighting can be satisfactorily run from these bars, notwithstanding the great variations of the power load. The connections are the same when the synchronous machine is acting as a generator to feed the three-phase network, except that the wattmeter relay is inoperative and hand regulation is used. The installation has been at work since April, 1907, and is in use day and night, excepting Sundays.

THE TELEPHONE EXCHANGE AT MESSRS. DEBENHAM AND FREEBODY'S

THE private branch exchange is now such a recognised necessity or all large business firms that a few words about the telephone exchange fitted at Messrs. Debenham & Freebody's establishment may not be without interest. A complete account of the electric light and power equipment appeared in our last issue.

Departments are kept in close touch with each other by means of this telephone system, some eighty telephones having been fitted throughout the building in the different departments and offices. The switchboard is built to accommodate two operators, and the different lines are distributed to equalise the traffic. The system

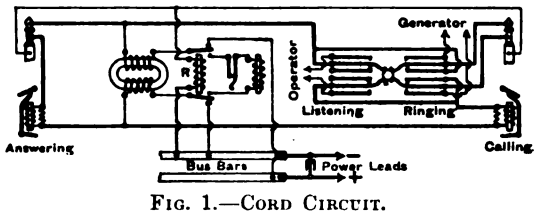

Fig. 1.—Cord Circuit.

R = Relay to cut off Local Battery on Exchange Connections.

is in touch with the outer world by means of eight junction lines connected to the Gerrard Exchange. At this latter exchange the lines are all consecutive and marked in conjunction, so that the operator can readily ascertain which lines are engaged when a number is required. By this means it is only on rare occasions that "line engaged" is given. Two lines are reserved for outgoing calls from this subscriber. The circuits are of the standard C.B. type, and are given above (fig. 1).

The calling apparatus consists of indicators of the "doll's eye" type, which, normally invisible, come into sight when an extension calls.

The ringing is done by a local plant consisting of a small motor generator; the ringing current is taken through a 660-ohm. lamp to prevent the possibility of current on the line that could heat up the apparatus.

There are twenty-four cord circuits, thirteen on the first position and eleven on the other, a number neces-

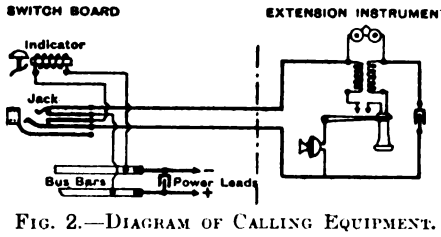

Fig. 2.—Diagram of Calling Equipment.

sary to cope with heavy traffic at certain periods of the day. The supervisory indicators are fitted immediately in front of their corresponding cords.

At night-time the exchange line is left plugged through for the use of the night-watchman and fireman. By this means calls incoming to the firm may be dealt with at any hour of the night.

THE MANCHESTER ELECTRICAL EXHIBITION: SUPPLEMENTARY LIST OF EXHIBITORS

THE Exhibition organisers have sent us the following list of exhibitors, supplementary to that published in our issue of August 20th. The total number of exhibitors is now about 230, which the organisers believe is greater than that in any previous trade exhibition ever held.

Abbey Electric Co., 17 Victoria Street, London, S.W.
Automatic Machine Co., Collier Street Works, Salford.

Bate, C. D., & Co., 40 Brazennose Street, Manchester.
Bateman Machine Tool Co., Balm Road, Hunslet, Leeds.
Bell Rock Belting Co., 24 Gravel Lane, Salford.
Birch, G. & Co., Ltd., Engineers, Manchester.
Birch, J. & Co., Ltd., 3 London Wall Buildings, London.
Brayshaw, Ltd., Engineers, Manchester.
British Thomson-Houston Co., Ltd., Rugby.

Combination Metallic Packing Co., Ltd., Hillgate, Gateshead-on-Tyne.

Dowsing Radiant Heat Co., Ltd., 24 Budge Row, London.

Electrelle, Ltd., Spring Gardens, Manchester.
Electric Rifle Co., Shaftesbury Avenue, London.
Elkington & Co., Ltd., 22 Regent Street, London.

Fittings, Ltd., 112 Victoria Street, London.

Griffin, J. J., & Sons, Ltd., Kingsway, London.

Harper Electric Piano Co., 238–262 Holloway Road, London.
Hughes & Stirling, Liverpool.

Kearney High Speed Railway Co., Ltd., 17 Old Queen Street, London, S.W.
Keith (James), & Blackman Co., Ltd., 27 Farringdon Avenue, London, E.C.

Luke, H., Ltd., Brazennose Street, Manchester.

Marples, Leach & Co., 24–30 Artillery Lane, London, E.C.
Mawdesley, Ltd., 25 Victoria Street, London.
Mealy, T. H., 87 Stovel Avenue, Manchester.
McPhail & Simpson, Ltd., Engineers, Wakefield.

Noyes, C. J., Pendleton, Manchester.

Phillips, J. W., & C. J., 23 College Hill, London.
Phillipson & Co., Holland Street, Astley Bridge, Bolton.

Small & Parkes, Ltd., Hendham Vale Works, Manchester.

Thornton, A. G., Ltd., 44 King Street, W. Manchester.
Triumph Stoker, Ltd., 85 Kirkstall Road, Leeds.

Vincit Co., 117B Queen Victoria Street, London, E.C.
Vulcan Boiler & Central Insurance Co., Ltd., King Street, Manchester.

Wellman-Seaver & Head, Ltd., 4–7 Victoria Street, London, S.W.
Wright, A., & Co., Ltd., 1 Westminster Palace Gardens, London.

ELECTRICAL ENGINEERING IN MEXICO

THE annual report of the British Consul-General in Mexico shows a considerable increase in the value of the imports from the United Kingdom. The large amount of mining work carried on in the country affords an excellent opportunity for the introduction of electrical machinery, although, of course, owing to the proximity of the United States, most of the imported machinery is of American manufacture. In his report, Consul-General Stringer states that British manufacturers and merchants could doubtless extend their trade with Mexico by sending out capable and energetic representatives, with a working knowledge of the Spanish language, to beat up trade on the spot. Catalogues, of course, help a great deal, but he emphasises the fact that it is of little or no use to send out catalogues and price lists in English; and that in giving weights and measures, the metric system should be used. The value of the imports under the heading of machinery and implements, which includes industrial, agricultural, and mining machinery, and also electrical appliances, was £2,780,000 for the year 1906-7.

In the report of the Vice-Consul for the State of Colima, it is mentioned that there are several factories using electric power, including two large ice plants. The electric light and power company's generating station in this district has been working for one year, but the plant installed is not of sufficient capacity to supply the power needed for local necessities. It is pointed out that during next year the State of Colima will be brought

Digitized by Google

within 12 days' journey (*via* New York) of London and within 20 days (*via* Southampton and Vera Cruz) of London, Paris and Berlin. The principal importers in Colima of foreign goods are German, and naturally they import principally German goods. The city of Colima is the largest and most important city on the Pacific coast of Mexico, and with the opening of the railroad from the interior will forge rapidly ahead. In this report also it is emphasised that to secure their share of the foreign trade British merchants should either send commercial travellers to solicit orders personally and display goods, or should send fully illustrated catalogues in Spanish to the principal importing houses. The present custom of sending English catalogues is, according to the report, worse than useless.

The Vice-Consul for Guadalajara gives the following information with regard to the currency and weights in vogue in Mexico :—The standard unit of currency is the Mexican peso, which, for purposes of ready calculation, is generally assumed to be the equivalent of 2s. The metric system is the legal system of weights and measures adopted by the Mexican Government, but the old-time units of weight are still much used in parts of the country, and it is, therefore, as well to state their names and equivalents :—

1 adarme	=	1·1500 dram
1 onza		1·0151 oz.
1 libra		1·0150 lb.
1 arroba		25·3776 lbs.
1 quintal		0·9063 cwt.
1 carga		2·7189 cwts.
1 toneladа		0·9063 ton

Writing of foreign competition, the Vice-Consul complains that few British commercial travellers make a speciality of Mexico, and the great majority simply take in the whole Republic as part of their general beat through Spanish America. It is very seldom that a British commercial traveller is seen in Guadalajara, and it is doubtful whether more than six visit this city in the course of a year. German travellers are, on the other hand, ubiquitous, and at least one hotel in Guadalajara is largely dependent on their visits for its revenue. The United States manufacturer floods Guadalajara and the whole country with handsome catalogues printed in the Spanish language, and in no case is any charge made for catalogues. With regard to the power supply in Guadalajara, the report states that the Guadalajara Tramway, Light & Power Co., which was organised in 1907 to effect the amalgamation of a French and Spanish company, at present generates 10,000 horse-power, derived from hydraulic power, but can raise that amount to 100,000 horse-power. A rival electric power company will shortly be organised, and an additional 75,000 horse-power can be furnished from the resources at its command.

That there is room for improvement in the methods of generating and distributing electrical energy is evidenced by the statement in the report of the Consul in Mazatlan that the town is well lighted by electricity, but that for the householder electric light is an expensive luxury in Mazatlan, since he must pay 4s. per month for a single 16 candle-power and £1 16s. per month for ten 16 candle-power lights. The writer of this report is of the opinion that exhibitions of British manufactures in Mexican towns would tend towards increasing British trade with Mexico.

ELECTRICITY IN AGRICULTURE

IN an American consular report, Consul R. J. Thompson, of Hanover, quotes some interesting passages from an address read before the Prussian Agricultural Society by Herr von Podbielski, former Minister of Agriculture. The address refers to farming on a large scale as being the only finally profitable system of agriculture, as it is impossible to make use of the improvements effected by modern science, and especially by the application of electricity, on small farms. The advantages of distribution at a high pressure over a large area from a central generating station are pointed out, and the system, in which a transformer in the farm building supplies a low-tension circuit consisting partly of several waterproof junction boxes distributed in the yards and fields, is described. To connect up any piece of apparatus to one of these junction boxes, a strong pliable cable from 50 to 100 yards long, and wound on a portable drum, is employed.

A motor of sufficient capacity for driving chaff-cutters, oil-cake breakers, pumps, and other agricultural machines can be easily carried about on a litter by two persons. The farm work proper lasts for only a few months of the year, and for this reason the motors are not permanently connected, and may be used throughout the year for all kinds of work, thus deriving the largest possible returns for the money invested. For instance, the motor that is used to drive the oil-cake breaking machine may also be used to drive a pump for draining water from swampy ground. Large motors must be put on wheels. By using belts, such motors can be used for all possible work, and especially with threshing machines.

There are electrical threshing machines in use where the motor is permanently connected with the machine. A number of such machines are in successful operation. Barns are equipped with electrical cranes lifting an entire load of hay at once and placing it in the loft in any desired position. Such an installation means the saving of numbers of farm hands. Some large farms use electric cars. The electric railroad of the great Dahlwitz farm, which for ten years has forwarded large quantities of farm products to the markets of Berlin and vicinity, may be cited. If even a very small profit is to be derived from agricultural work, the farmer is bound to use machinery instead of manual labour, because the wages for the latter are steadily increasing. Electricity is the power best adapted to the work. Until very lately, however, it could not be used extensively on account of the high price per kilowatt-hour, charges of from 40 to 60 pfennigs (5d. to 7d.) per kilowatt-hour, excluding its use for agricultural purposes. According to Herr Podbielski's calculations, the price per kilowatt-hour in Germany, in order to leave a reasonable profit, should be no more than 20 pfennigs (2·4d.), and if modern machinery is employed, it is possible to furnish electricity at such a price. At our coal centres the kilowatt-hour is already furnished at from 6 to 7 pfennigs (0·7Zd. to 0·84d.).

The use of electricity in agricultural work may be classified as follows : (1) About the barnyard, as working the chaff cutter, corn cleaner, bruising mill, hauling crane, &c., unloading of hay, and, on large farms, smithy and cartwright work, and, further, for lighting the stables and the houses; and (2) in the fields, pulling the plough, running the machines, reapers, &c., and threshing. There is no difficulty in installing the machines referred to in the farmyard, but the expense for the use of electricity in the fields is much too high as yet. The cables are too expensive, and the plough run by electricity does not as yet work satisfactorily.

THE MANUFACTURE OF METAL FILAMENT LAMPS

ALTHOUGH there are now metal filament lamps of various types on the market for running at pressures over 200 volts, these have necessarily long filaments, and give out correspondingly large amounts of light. The problem of increasing the specific resistance of the tungsten, tungsten alloy, or other metal from which the filaments are manufactured still engages the attentions of the lamp manufacturers, and the patent specifications which are published from time to time give an idea of what is being done in this direction. Our Patent Record for last week contained, in the list of specifications published last Thursday, two patents relating to this subject.

The first was taken out by the Elektrische Glühlampenfabrik "Watt" of Vienna, and described a process for obtaining filaments consisting of an alloy of tungsten and one or more of the other refractory metals, such as titanium, thorium, or vanadium. The process consists in intimately mixing powdered tungsten with powdered oxides of the above metals and a binding agent containing carbon. The proportion of pure metal in the filament should be only just sufficient to render the cold raw filament a conductor. The paste formed is shaped into filaments, and these are heated in a chamber from which air is excluded. After the above treatment the filaments are raised to a white heat in an atmosphere of hydrogen. The oxides are reduced with the aid of the carbon in the binding agent and the hydrogen, and an alloy of the tungsten and the metals from the oxides is produced. The value of such alloys as, for instance, tungsten with thorium or titanium resides in the fact that they have high melting points and a much higher specific resistance than pure tungsten. This last property would enable the length of the filament

Digitized by Google

for a given pressure to be considerably reduced, and would render the manufacture of high voltage low candle-power lamps a possibility.

The second of the two specifications is one by the Glühlampenfabrik "Union" of Berlin. The process of manufacture in this case is entirely different, and the final filament consists of tungsten or molybdenum or an alloy of these two metals, and silver. The incorporation of silver into the filament is said to increase the specific resistance and to render the filament less brittle. The process consists in heating carbon filaments to a temperature of 600° C. by passing a current through them, and at the same time exposing them to the action of the vapours of salts of tungsten or molybdenum, such as the chlorides, which readily evaporate in a vacuum. Hydrogen is introduced at the same time, and the metals are deposited on the carbon filaments, the chlorine combining with the hydrogen. The silver is incorporated into the filaments either beforehand by treating the carbon filaments with a solution of a silver salt, or at the same time by introducing silver chloride along with the tungsten and molybdenum chlorides. If desired, the carbon can then be completely burnt out of the finished filament by raising the whole to a high temperature in an atmosphere of hydrogen.

CORRESPONDENCE

To the Editor of "ELECTRICAL ENGINEERING."

SIR,—I have to thank your reviewer of my little work on "The Slide Rule" for several compliments, not all, perhaps, intended. When he states that it is likely to "produce slaves to the slide rule," surely there is an implied tribute to my descriptions of the appliance and its uses. One's description of a thing must "live" if it captivates the reader so that he becomes an actual slave to the thing so glowingly described. In regard to the "surprising dearth of the definite article," it is a curious fact that in the first 100 words of the review itself the definite article occurs eleven times (some are mere quotations), whereas in a passage of similar length selected at random from my book it occurs ten times. In sentences like the following, "Set *the* cursor to 264 on *the* C scale and bring 345 on *the* D scale to *the* cursor," which constitute a large portion of the work, it is evidently only a tribute to the writer's commonsense to call attention to the fact that he in later chapters omits the definite article. The word "delogarise," to which your reviewer objects, is not mine—I wish I could invent anything so good. Like most of the terms due to Prof. Perry, it "gets there" better than another author's sentence. Suppose, for instance, one is working out a calculation by logs., and one finds that the logarithm of the answer is, say, 2·351, the English of the operation to be performed is "*find the number of which* 2·351 *is the logarithm*"; another version is, "*find the antilogarithm of* 2·351," but the term "anti-logarithm" has no real relation to the operation indicated. Perry's nomenclature is "*delogarise* 2·351," which indicates in the shortest and most concise way the actual operation involved.

I think there are few mathematicians who would not be proud to father such an apposite and expressive term. I am glad to copy it.

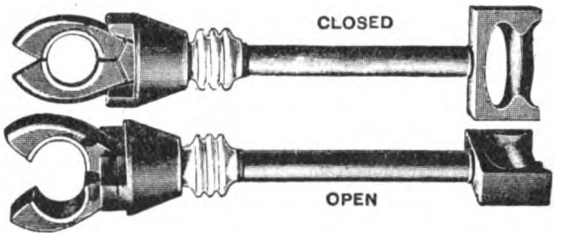
Yours, &c.,
R. G. BLAINE.

International Exhibition in Turin.—An international industrial exhibition is to be held in Turin in 1911. The sections will include electricity, measuring instruments, and transportation (tramways and railways). The programme and regulations (in English) may be seen at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

"The Electron."—The first two numbers of this monthly magazine, the official organ of the Siemens Stafford Institute, were reviewed at some length in ELECTRICAL ENGINEERING, August 13th, page 241. The third number, which has just been published, contains as a frontispiece a plan of the Stafford works. The biography of Ernst Werner von Siemens, which is given at some length, is the second of a series of biographies of prominent "Siemens" men, the first of which was an historical sketch of some of the earlier members of the Siemens family. A Paper on "Sparking: its Causes and Cure," read by Mr. S. P. Smith before the Engineering Society, and the concluding instalment of the discussion to Mr. M. Schenkel's Paper on the "Siemens-Schuckert-Werke Single-phase Series Motor" are included in this number. There are three short articles and several notes relating to the athletic, literary, and other social sections of the institute.

FUSE TONGS

MR. FRITZ LÜLING, of Küsnacht, near Zürich, has sent us particulars of a new patent tongs for removing and replacing fuses. He states that it can be used with safety for fuses up to 40,000 volts, or even higher, and that it can be manipulated with one hand. The illustration below indicates clearly the mechanism used. The handle is of wood, and is insulated from the tongs themselves by a corrugated insulator which has been tested up to 40,000 volts. As soon as the tongs



are placed against the fuse they open automatically, embrace the fuse tube, and close again. The handle is then turned slightly, and this locks the tongs, so that the fuse can be withdrawn. In inserting the fuse, the reverse action, of course, takes place. The tongs are made in three sizes: those for diameters of $1\frac{3}{16}$ inches are $13\frac{3}{4}$ inches long, and those for diameters of $2\frac{1}{4}$ inches and $3\frac{1}{16}$ inches are $27\frac{1}{2}$ inches long. It is stated that the tube is gripped uniformly all round, so that there is no risk of its breaking.

THE "OVERSHOOTING" OF TUNGSTEN LAMPS

IN an article by J. Stuart Freeman in a recent issue of the *Electrical World* some experiments are described which give conclusive evidence of the "overshooting" of tungsten filaments. Among the rapidly increasing number of users of the tungsten incandescent lamp, doubtless many have noticed what appeared to be a sudden rise in candle-power, upon turning on the current, to far above normal, then a gradual decrease to the operating brilliancy. The first investigation that was made settled the fact that the phenomenon is a reality and not a mere illusion. Apparatus was constructed for making a continuous photograph of the intensity of the rays emitted from the lamp after turning on the current, first when the lamp had been cold, and again after the lamp had been hot for some little time. This was done by revolving a cylindrical film holder in a lathe at a known speed and feeding before the exposing slot a card with a small hole in it, through which the rays of the light could shine. By this means it was demonstrated that there is certainly an "overshooting" of light intensity at the moment of turning on the current, and that it lasts for about one-tenth of a second. This, however, occurred only after the lamp had been turned out for some time, or, in other words, when it was cold. After being lit, then extinguished, and again lit, after the elapse of a second or so, the phenomenon was not visible.

This experiment suggested to certain engineers the use of the oscillograph in the investigation of the subject. In these investigations a 22-volt tungsten lamp was placed in an enclosed tube inside the oscillograph box so that the light could shine, through a small aperture, on to the revolving film. The current wave was obtained by connecting the vibrator across a shunt in series with the lamp. By means of a contact-making device and a small relay, operated by the same current that controlled the oscillograph shutter, the lamp circuit was automatically closed, thus obtaining on the same film both the current wave and the actual intensity of light emitted from the lamp. All the records were taken from a direct-current source. The current went directly to the lamp and instrument, with neither reactance nor resistance in the circuit.

These experiments showed that the total excess of brilliancy on switching on lasted for about one-fifth of a second, and the greater excess for one-tenth of a second only. The difference between the time when the current was turned on and when the filament reached incandescence was very short, being only one-sixtieth of a second, but the filament held its high temperature for fully one-thirtieth of a second after the current was turned off.

From readings taken, it was shown that the lamp was running on a steady direct E.M.F. of 22 volts, and that the initial current was 5·7 amp., while the final current was 0·68 amp. The total exposure to the lighted lamp was one-quarter of a second and the duration of the greatest "overshoot" in the current was about one-fiftieth of a second. A photograph taken when the filament was still warm, owing to a previous lighting, showed that there was no "overshooting" as regards excess of light,

Digitized by Google

but that the same ratio existed between the initial current and the final current.

It was found that an entirely different state of affairs exists in the case of a carbon incandescent lamp of the same candle-power, namely, 16. This was also run on a direct current with no resistance in the circuit. The voltage was 120, and the initial current was but 0·15 amp., while the final current was 0·3 amp. It took approximately one-fifth of a second for the current to become normal. This easily illustrates the comparative susceptibility of filaments made from each of the two elements. By comparing these two records we find that while the current of the tungsten lamp "overshoots" its normal point of operation when turned on, and then decreases to it, the current of the carbon lamp starts low and increases to normal, at no time exceeding that point. This is, of course, due to the fact that whereas the resistance of the metal filament increases with increasing temperature, the resistance of the carbon filament decreases. Further, the difference in the number of watts necessary to produce 16 c.p. in each of the two lamps is quite noticeable, for while the tungsten lamp, running on 22 volts, started at 5·7 amp., and ran on 0·68 amp., the carbon lamp, running on 120 volts, started on 0·15 amp., and ran on 0·3 amp.

Lastly, a record was made from a film revolved at 120 revolutions per minute, which showed all of the above characteristics concerning the tungsten lamp, and an additional phenomenon. In making this record, a 25-volt tungsten incandescent lamp was run on a 25-cycle, alternating-current circuit. The current kick was shown at the instant of closing the circuit, and also the alternate heating and cooling of the filament, corresponding to the alternations of the current wave. On closing the circuit there were 3·4 amp. effective, while at normal there was but 0·3 amp. effective. It was noticed, however, that the filament began to brighten at the maximum point of the wave, and itself reached a maximum at one-eighth of a cycle farther along, or a point midway between maximum and zero on the descending part of each wave. Also that the minimum brilliancy was not at zero, as might be expected, but at one-eighth of a cycle farther along.

As a result of these tests there seems to be no question that the suppositions of the first investigator, who made known his experiments in this line, and others thinking the same way, are correct; and there is nothing further that can be done to prove more conclusively the above, since clear records made by the oscillograph are universally accepted as proof.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

THE *Westdeutsche Thomas-Phosphat-Werke*, of Berlin, describe in the German patent 200,876 (1908) a process for manufacturing oxides of nitrogen by electric discharges through air containing some gas or vapour mixed with it which will cause an explosion. For example, oxy-hydrogen gas or ether vapour is mixed with air, and then this explosive mixture is subjected to the action of the electric discharge. By means of the explosion thus brought about, an extremely high temperature is produced which causes oxidation of the nitrogen. The reaction, however, is so extremely rapid that there is no time for a reverse reaction—the decomposition of the oxides of nitrogen already produced—to take place. It will be remembered that in the Birkeland-Edyde and similar processes one of the chief points is the rapid removal of the oxidised nitrogen from the zone of reaction. Dr. M. Platsch (German patent 200,138 of 1908) endeavours to arrive at the same end by blowing finely powdered peroxides directly past the arc to cool the gases the moment they have been oxidised. The peroxides also give up oxygen in *statu nascendi*, and thus increase the oxidation of the nitrogen. The oxides employed are readily regenerated, and the nitrites and nitrates are readily removed from them.

Heinrich Fassbender publishes in the *Zeitschrift für Physikalische Chemie*, 62 (1908), p. 743, notes upon some experiments which he has carried out in connection with the "influence of the silent electric discharge upon explosive gas mixtures." He finds that a mixture of oxygen and carbon monoxide explodes more readily and with greater energy after being subjected to the action of the silent electric discharge, probably owing to the formation of ozone. An interesting point was brought out when a mixture of carbon monoxide and oxygen was exploded without being subjected to the silent discharge, as the residual gases coloured iodised starch paper blue, showing that ozone had been produced. When a mixture of hydrogen and chlorine was subjected to the silent electric discharge and then exploded, no difference in the speed of reaction was noticed. In this case, as no oxygen is present, the formation of ozone is not possible. If the gases are ionised by means of the silent discharge, they immediately become molecular again when the influence is removed. It appeared, however, that, in consequence of the action of the discharge upon a carefully dried mixture of hydrogen and chlorine, larger quantities of hydrochloric acid were produced by the explosion. Likewise, larger quantities of CO_2 were formed when a mixture of CO and O was subjected to the discharge. The action of the discharge at times caused union of the gaseous products with explosion and flame formation.

In the *Gazetta l'Elektrician*, XV. (1908), p. 357, a comparison of the largest electric furnaces is given. There are now several Kjellin furnaces capable of dealing with 20 tons of steel, and requiring 1,000 h.p. to work them. Stassano and Keller furnaces of a like capacity have also been built. In connection with the manufacture of calcium carbide, the Pieonteschen Co., of St. Marcel, have furnaces taking 1,000 h.p., 1,500 h.p., and the largest, 2,500 h.p. A new carbide works at Dargo has in one enormous room 10 1,000-h.p. furnaces. In the manufacture of ferrosilicon, Keller and Leleux have built three furnaces which together take 5,000 h.p.

In the July number of the *Physical Review*, Mr. G. A. Hulett describes a form of cadmium cell which is suitable for supplying a small current of much greater constancy than that which can be obtained from an accumulator. It consists of a wide-mouthed bottle which has a diameter of about 8 cm. The bottom of the bottle is covered with a layer of mercury about 0·5 cm. in thickness, which in turn is covered to a depth of 4 or 5 cm. with a solution of 10 c.c. concentrated sulphuric acid and 0·800 grm. cadmium sulphate per litre of water. A little above the surface of the mercury a shallow glass vessel 4 cm. wide and 4 mm. deep is supported, which contains the 12·5 per cent. of cadmium amalgam. The mercury and the amalgam are joined together by means of wires enclosed in tubes. The mercurous sulphate is prepared in the cell itself by sending a current through it from the mercury to the amalgam, the solution being well stirred in the meanwhile. The internal resistance of the cell is 6 ohms, and it can give a current of 0·00001 ampere for a number of days without the E.M.F. varying appreciably. A larger cell has been prepared which gave a constant current of 0·04 ampere over a long period.

Dr. F. W. Alexander, in his annual report to the Poplar Borough Council, states that the electrolytic apparatus for the preparation of hypochlorite disinfectant is still working in a satisfactory manner. Daily 185 gallons of the fluid are produced in eight hours, which contains, on the average, 4·5 to 5·0 grm. of active chlorine per litre. The cathodes, it will be remembered, are of zinc, and the anodes of platinum wire wound upon slate. The zinc electrodes have not required to be renewed, although the plant has been in operation for over two years. To prevent the action of the salt upon the interior of the supply tank, it has been coated internally with "Rosbonite," a preparation which is stated to answer the purpose admirably. The total cost of the plant to the end of January, 1908, was £606, and the hypochlorite fluid manufactured in the two years was 32,386 gallons at a total cost of £1,009. Dr. Alexander estimates that the initial cost, £583, and a further sum of £398 have been been saved to the borough by the employment of the electrolytic disinfectant in place of the older chemical methods before used.

In the *Zeitschrift fur Elektrochemie* of August 21st, Gilbert N. Lewis contributes an article upon the "Determination of Ionic Hydration by Means of Potential Measurements." He considers that in the theory of concentration cells an important omission is always made. It is considered that the E.M.F. is the actual measurement of the energy liberated when the changing of a salt of higher to lower concentration takes place. This, however, is only correct when the changing over of the salt is the only process which takes place when the current passes through the cell. If in the solution the ions are hydrated, then, when the current passes, water will be transported in both directions, and if the cation or the anion carries more water in the one direction, then the result of the passage of the current will result in more water being carried in one particular direction; and, as the activity of the water is not the same in dilute as in concentrated solutions, the transport of the water will be accompanied by a change in the free energy. Consequently, the electrical work which is obtained from a cell when an equivalent of electricity passes through it is the sum of two quantities, the one being produced by the ionic transportation, and the other from the water transport. The method of measurement employed is to use on one side of the system a thallium electrode and a saturated aqueous solution of thallous chloride, and on the other side a thallium electrode and a solution of thallous choride in a molecular sugar solution. When the current passes through such a combination it is possible for four materials to be transported—(1) metallic thallium, (2) thallous chloride, (3) water, and (4) sugar. It is, however, considered that sugar does not combine with the ions, and, consequently, is not transported with the ions. From the other three processes the two first cause no work, because the activity of the thallium and the thallous chloride is the same on both sides. On the other hand, the activity of the water is 2 per cent. less in the sugar solution. Consequently, the water transportation is the only process in which a change of energy is bound up. Therefore, the E.M.F. of the cell is a direct measurement of the transported water. An experimental confirmation of the method has commenced, and promises to yield valuable results.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Aug. 27th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

1907 Patents

17,660. **Safety Device for Lifts.** M. J. McVITTIE. An automatic electromagnetic brake for preventing the fall of a lift-car on the breakage of the suspension rope. The car runs between steel guide rails, and two electromagnets fixed to the sides of the car have poles shaped to the profile of these rails. The poles of the electromagnets are kept in contact with the rails by means of springs, and thus take the place of the usual guiding shoes. A spring, normally held in compression by the tension in the suspension rope, closes a circuit on being released by the breakage of the rope. This causes the electromagnets to be energised, and the car is thus held firmly to the guide rails. By reducing the current the grip of the magnets may be reduced and the car allowed to slide down. By connecting a small lamp in parallel with the brake circuit, failure of pressure will be indicated. Three claims, four figures.

17,718. **Lifting Magnet for Arc Lamps.** DEUTSCHE BECK-BOGENLAMPEN GES. Arc lamps in which the electrodes are brought into contact through the action of a weight often fail to strike owing to the weight being insufficient to overcome the frictional resistance of the lifting mechanism. The present invention is a design of lifting magnet to overcome this fault. Connected to the feeding mechanism is a rod which has a head held loosely within a recess in the magnet core. The rod is attached to a piston moving in a damping cylinder which may contain air or liquid. On cessation of current the magnet core drops, collides with the rod head, and operates a valve so that the piston falls easily and allows the electrodes to touch. One claim, one figure.

21,904. **Automatic Reverse-current Circuit-breaker.** A. ECKSTEIN, A. C. HEAP, and D. B. MELLIS. A reverse-current circuit-breaker for use on continuous-current circuits, and consisting of two coils wound separately on an iron core. The iron circuit is so shaped and the coils so placed that each coil has nearly a complete iron circuit independent of the other coil, but in each case the circuit is broken by a short air-gap. The two coils have a common magnetic circuit with no air-gap, so that as long as the currents in the two coils are in the same directions the flux traverses the common path. Should the current of the one coil reverse, the fluxes take the independent paths, and as the flux density is considerably reduced owing to the gaps, the armature is released and the circuit-breaker is operated. The chief advantage claimed is that there is very little tendency for the reverse current, even though very great, to reverse the field through the unidirectional current winding, and thus retain the armature, as the reverse current winding has its own magnetic circuit. Two claims, two figures.

1908 Patents

1,773. **Control of Single-phase Traction Motors.** E. F. ALEXANDERSON. Arrangements for enabling commutator traction motors to be run with single-phase or direct current at the highest possible voltages in both cases, thus reducing copper sections in the motors themselves and in the control circuits. The motors are operated as repulsion motors on alternating current, and as series motors on direct-current circuits, and the pressure for alternating-current working is made double that for direct-current working, without increasing the strain on the insulation of the motors, by earthing the middle point of the secondary of the main transformer. Means for short-circuiting the armature for alternating-current operation, without breaking the series connection, is provided. To give the necessary increase in the compensating ampere-turns relative to those of the exciting winding when changing over from series motor to repulsion motor connection, the compensating windings are divided, and are connected in parallel for direct-current operation and in series for alternating-current operation. For direct-current operation the armatures and exciting windings are connected in series. For alternating-current operation the exciting windings are supplied direct. Six claims, four figures.

7,006. **Petrol-Electric Transmission System.** F. PORSCHE (AUSTRIAN DAIMLER MOTOR CO.). A method of transmitting power from a prime mover, such as a petrol engine, to the wheels of a vehicle, and maintaining a constant torque of the engine in spite of the variable load. Two electric systems, each consisting of an armature and field magnets, are mounted concentrically, and are capable of a certain amount of longitudinal movement. Owing to the conical shape of the armatures and the bores of the field magnets, this movement causes the air-gap of one system to be increased while the other gap is reduced. These variations of the gaps are accompanied by corresponding variations of the flux density. The engine is connected to the electrical machine by means of a spring and on an up-gradient, the spring yields, causing the motor gap to be reduced and the dynamo gap to be increased. The speed is reduced, and thus the power kept constant. Five claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

10,855, DELAGE & WOOG. Ignition devices for explosion motors.
11,185, MAVOR, HIRD & MAVOR, & COULSON, Ltd. Speed control of alternating current motors.
15,846, FENNELL & PERRY. Methods of electrical distribution.
17,981, SHEPPARD. Automatic control of the speed of a motor.
18,165, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Automatic telephone exchanges.
18,210, MONGE & ARZANO. Electrolytic processes for covering silvered mirrors with a protective metal layer.
18,348, FENNELL & PERRY. Electrodes for storage batteries.
18,527, NEALE. Railway signalling apparatus.
18,537, PHILLIPS. Electric musical instruments.
18,582, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitats-Ges.*). Protective devices for electric systems.
18,688, LOWDEN. Incandescent electric lamps.
19,348, FLOHR. Manufacture of iron or steel with the aid of electrical furnaces.
20,508, VANDERVELL. Sparking coils for internal-combustion engines.
20,867, ALLGEMEINE ELEKTRICITÄTS GES. Alternating current machines of the commutator type.
22,405, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Systems of electric motor control.
22,481, ALLGEMEINE ELEKTRICITÄTS GES. Control of electric motors.
23,418, TURNER. Electric transformers.
23,786, GIMINGHAM. Manufacture of electric lamps.
24,589, POOLEY & MACDONALD. Protective devices for electric circuits.
24,808, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Alternating current machines.
25,115, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Systems of generating and distributing electric current.
25,148, ASHTON & ASHTON. Electric ignition in combustion engines.
27,225, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electrical protective devices.

1908 Patents

2,195, DERAIN. Dynamos.
4,030, TIDNAM. Telegraph poles.
4,261, MARKS (*National Regulator Co.*). Apparatus for automatically controlling the temperature in buildings.
4,568, TAYLOR & BROOM. Electric arc lamps.
5,159, PIEPER. Electro-mechanical transmission systems for automobiles.
6,173, GROSWITH. Electric couplings for fire and other hose containing embedded conductors.
6,181, BOCK. Railway signalling.
6,450, BLIVEN. Trolleys or collectors for electricity.
6,555, MERGUIN. Connection for cables.
7,571, BROOKES (*Cushman Electric Co.*). Field magnets for dynamo electric machines.
10,118, VON GIZINSKY, MCCLURE, & WIESNER. Electric railways and tramways.
10,273, SNYDER. Sanding apparatus for tramcars.
12,876, SIEMENS-SCHUCKERT WERKE GES. Device for starting internal-combustion motors.
14,698, Firm ROBERT BOSCH. Carbon brush holders for magneto electric igniters.
16,538, MONGE & ARZANO. Electrolytic processes for covering silvered mirrors with a protective metal layer.
16,539, MONGE & ARZANO. Electrolytic processes for covering silvered mirrors with a protective metal layer.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

3,388, HOWELL. Incandescent electric lamps.
8,018, MEYERLING. Ampere-hour meters.
14,480, HOLMES & ALLEN. Trolley-heads for electric traction.
15,864, AUVERT & FERRAND. Device for suppressing stray fluxes in rotary transformers.
16,534, COOLIDGE. Manufacture of refractory conductors.
16,542, OTTO. Production of ozone.

Expiring Patents

No patents of electrical interest expire during the current week.

THE EALING TRAMWAY DISPUTE

ON page 274 of our issue for August 20th, we reported the circumstances of an inspection by Col. Yorke, the chief inspecting officer of railways of the Board of Trade, of the tramways between the Ealing Town Hall and the Hanwell Boundary. It may be recalled that two previous inspections had been complained about by the Council as not being sufficiently thorough, the reason for the inspections being alleged noise from the tramways, due, it was said, to insufficiently heavy track, upon which were run too heavy cars. The amusing incidents connected with the last inspection were recorded in our last issue of August 20th, and we are now able to publish Col. Yorke's report:—

I have the honour to report for the information of the Board of Trade that in compliance with the instructions contained in your minute of the 5th instant, I have this day inspected the tramways in Ealing.

I was met at the borough boundary by the Mayor and Surveyor of Ealing, and I asked them at once to point out to me any places in the tramways concerning which they wished to make complaint. As there appeared to be no bad places near the boundary, I told the Mayor that as a complaint had been made, that on the occasion of my previous visit in August, 1907, I had not inspected the whole route, I proposed on this occasion to walk over the whole tramway line from boundary to boundary, and this I did. The Mayor and Surveyor did not accompany me, but proceeded to the Town Hall, where they awaited my return. I walked over the route along the centre of the road, and examined the whole of the tramway tracks, and I found them to be in fair order, and in a better condition than I anticipated.

There were evidences that numerous repairs had been executed within the last week or two, and in some cases within the last day or so, and the officers of the company made no secret of the fact that many repairs had been recently carried out, and are still in progress. Some of these repairs were rather rough, and showed signs of haste.

After a careful examination of the tracks from end to end, I have to report for the information of the Board of Trade that in my opinion the London United Tramways within the Borough of Ealing are not at the present time in such a condition "as to be a danger or annoyance to the ordinary traffic."

Some facts relating to the laying of the tramways in Ealing make interesting reading. When the agreement between the Council and the company was arrived at some seven years ago, the company, at the special request of the Council, laid their track with blocks of a special Californian wood, a material which was also employed by the Middlesex County Council at the desire of the Ealing Council for the remainder of the roadway. It was soon seen, however, that these blocks wore down very quickly, and the company are gradually executing repairs with hard Jarrah wood blocks. But on either side of the track the original blocks remain, and it is notorious locally that they are in an exceedingly bad condition. In fact, a ratepayer has ventured the opinion that the expedition with which Col. Yorke carried out his inspection is clear proof that, at any rate, he was walking on the tramway tracks, as had he been walking on the sides, he would have been soon tired out with "falling into holes and climbing out again." Further, the Middlesex County Council refuse to renew the roadway yet for reasons well known both to itself and the Ealing Council. Against the imputation that the company is able continually to hoodwink the Board of Trade inspector by hurried repairs just prior to the inspection, comes the suggestion that if the Ealing Council could prevail upon the Board of Trade to order the tramway track to be entirely relaid, they would be in possession of a lever for forcing the Middlesex County Council to deal with the remainder of the roadway at the same time.

LOCAL NOTES

ARGENTINE: *La Plata Electric Supply.*—The *Review of the River Plate* states that the Senate of the Province of Buenos Aires have before them a petition for leave to establish a new electric light and power works in the City of La Plata. The Bill has been approved in general, and the Minister of Public Works spoke in favour of the project. There is considerable discontent at the present time in La Plata in connection with the River Plate Electricity Co., which is principally due to the charge of $2·50 a month made for meters, but our contemporary does not think that there is room for two companies in La Plata, seeing the hold that the existing company already has in that city.

AUSTRALIA: *Footscray (Victoria).*—According to the *Australian Mining Standard*, the Lighting Committee of the Footscray Council propose recommending to the Council that steps be taken to bring the electric light into existence. A poll of the ratepayers is to be taken to obtain their sanction to the floating of a loan for the purpose.

Brunswick (Victoria).—The proposal made some time ago by a syndicate to supply the town of Brunswick and the adjoining borough of Coburg (V.) with electric light and an electric tramway service, was considered last week by the Brunswick Electric Lighting Committee, and was rejected, although the Borough Council of Coburg had decided in favour of it. However, the Lighting Committee had no actual power to veto, and the matter will not be finally disposed of until dealt with by the City Council at its forthcoming meeting, and it is not at all certain that the committee's recommendation will be adopted. To reject this offer, as a previous one was rejected, would necessitate the borrowing of a large sum for the purpose of installing a municipal plant, and to this there is strong objection in the Council.

BARGOED: *Telephone Service.*—At the last meeting of the local Chamber of Trade, a letter from the Postmaster-General was read, stating that he had given instructions for the extension of the telephone and telegraphic system to Bargoed. Efforts are now to be made to obtain a trunk line between Bargoed and Cardiff.

BARNSTAPLE: *Electric Light Tariffs.*—The Lighting Committee have made a report recommending a system of two rate meters for large consumers. The Council has confirmed the arrangement, which is that all consumers for lighting of over 2,000 units per annum be offered a two-rate meter method of charging, namely, 4½d. per unit between 6 p.m. and 11 p.m., and 2¾d. per unit between 11 p.m. and 6 p.m. No discount will be allowed to consumers taking advantage of this system. This will not apply to public lighting.

BECKENHAM: *Metal Filament Lamp Tests.*—The Electrical Department is carrying out some exhaustive life tests on metal filament lamps used for street lighting. The lamps are being run night and day.

BELFAST: *Tramway Matters.*—At the weekly meeting of the Tramways and Electrical Committee on the 31st ult. the Town Clerk was instructed to have a draft agreement prepared *re* the running powers of the Cavehill and Whitewell Tramway Co. over the Corporation's lines.

BIRMINGHAM: *Tramway Extension.*—The proposal that the Birmingham Corporation should extend its tramway system into Stechford continues to receive support. A meeting of the local Ratepayers' Association was held last week-end, when a resolution was passed urging the City of Birmingham to negotiate with the Yardley Rural District Council to promote a Bill in Parliament authorising the proposed extension.

BRAZIL.—*Advertising Methods.*—H.M. Consul at Pernambuco, Mr. P. Staniforth, writing with reference to the methods of foreign competitors with which a British exporter has to contend, mentions that a representative of a German electrical firm fitted an installation of electric lamps and accumulators to a carriage of one of the Pernambuco suburban railways, free of charge, to show the advantages of his firm's special system with a view to orders.

BRIDLINGTON: *Condition of Electric Plant.*—A report has been received from the National Boiler & General Insurance Co. to the effect that the boilers, engines, and economisers at the Electricity Works are in good order.

Digitized by Google

BRIGHOUSE: *Electric Lighting Loan Refused.*—The Local Government Board has refused to sanction a loan of £3,624 for the purpose of replacing old generating plant which has been disposed of in consequence of the decision of the Council to abandon generating electricity itself in favour of taking a supply in bulk from the Yorkshire Electric Power Co. The Council has also applied for a loan of £3,940 for a sub-station in connection with the bulk supply, but a communication from the Local Government Board asks for further particulars with regard to this before a decision is given.

BURY: *New Generating Station.*—Plans are now being prepared for the new Corporation electricity works, which are to cost about £80,000.

CAERGWRLE: *Electric Lighting.*—A scheme of electric lighting has been reported upon favourably.

CARDIFF: *Visit of Associated Chambers of Commerce.*—Arrangements have been made for those attending the meeting of the Associated Chambers of Commerce in Cardiff to inspect the electricity and tramway undertakings.

CHICHESTER: *Electric Lighting.*—Negotiations are being carried on between the Board of Guardians and the Chichester Electric Lighting Co., with regard to the installation of electric light in the workhouse, but the Guardians refuse to pay the expense of wiring, holding the opinion that the cost should be borne by the company.

CHINA: *Telegraphs.*—A new telegraph line is being built along the river at Shantung, with the combined object of improving the present service, and of giving flood warnings.

COLWYN BAY: *Tramways.*—The extension of the Llandudno and Colwyn Bay tramways on to Old Colwyn is contemplated, but the County Council and the Urban District Council have to carry out considerable road widenings before the actual work upon the lines can be commenced.

EDINBURGH: *Exhibition Lighting.*—The formal inauguration of the scheme of decorative electric lighting of the buildings at the Scottish National Exhibition took place last week, Sir Robert Cranston, ex-provost, presiding. At present only the buildings have been dealt with, but the grounds will also be included in the scheme, which, when completed, will comprise some 20,000 lamps.

GLASGOW: *Tramway Accounts.*—From June 1st to date the Corporation tramways have carried 49,567,109 passengers, compared with 50,030,993 passengers during the corresponding period of 1907. The total revenue from June 1st amounts to £204,091, against £203,382 for the corresponding period of the previous year.

GREYSTONES: *Electric Lighting.*—The Greystones Electric Lighting Co. has again made an application to the Council for permission to their application for an electric lighting provisional order, but the consideration of the matter has once more been deferred.

GUATEMALA.—*Electrical Imports.*—The total value of the imports under the heading of electrical appliances and material, from the United Kingdom, Germany, and the United States amounted to £8,110 during the year 1907. The individual amounts were £240, £5,660, and £2,210 respectively. The figures for 1906 were £101, £3,140, and £5,600 respectively. Thus the British and German imports have increased; those of the United States decreased.

HALIFAX: *Runaway Tramcar.*—Whilst ascending Gibbett Hill, Halifax, on Thursday, a tramcar began to run back, and, on the curve near the bottom it left the rails and came to a standstill at the kerbstone opposite a jeweller's shop. No damage was done to the car, but sixty workmen jumped off the vehicle, and one sustained a sprained ankle.

HASLINGDEN: *New Tramways.*—The Board of Trade will make an inspection of the reconstructed tramways this week. The Accrington Council are providing the cars and current, for which Haslingden pay 7d. per car mile. The arrangement is for nine months, to give Haslingden time to erect their own generating station.

HYTHE: *Tramways.*—One of the conditions imposed by the Council when the National Electric Construction Co. secured their Bill for the construction of tramways in the district was that the surface-contact system should be used. Now, however, the company, owing to the extra cost, are seeking to substitute the overhead trolley system, and as there is considerable difference of opinion amongst the inhabitants on the matter a poll of the ratepayers is being taken.

INDIA (CALCUTTA).—*Electric Power.*—In an American Consular Report, Consul-General W. H. Michael, of Calcutta, states that electric power for domestic and mechanical purposes has become almost a necessity in Calcutta, and a reduction in the cost would have the effect of largely increasing the consumption of electric energy.

ITALY.—*Electric Lighting.*—It is reported from Castellammare di Stabia that a small generating station with steam turbo-alternators for supplying light and power in the district will shortly be opened.

LONDON: *London County Council: Tramways.*—It is stated that all difficulties in the way of the conversion of the remaining horse tramways in Battersea and Wandsworth have been removed as the result of prolonged negotiations between the Battersea Borough Council and the Highways Committee of the London County Council. Work will be proceeded with at once on the Queen's Road and Chelsea Bridge Road route, whilst a tentative agreement has been arrived at with regard to the line from St. John's Hill to Vauxhall, which awaits confirmation by both Councils. Both the lines will be reconstructed upon the conduit system, but owing to the very low railway bridges in Queen's Road only single-deck cars will be used on this route.

MALVERN: *Assistant Engineer's Salary.*—The Urban District Council on Tuesday unanimously confirmed the Electric Lighting Committee's recommendation to advance the salary of Mr. C. E. D. Greenhalgh, the Assistant Electrical Engineer, by £20 per annum.

MANCHESTER: *Telephones in Public Libraries.*—The Libraries Committee have arranged with the National Telephone Co. for placing telephone facilities at fourteen branch libraries.

Tramwaymen's Flower Show.—The employers of the Manchester Corporation tramway department held their annual flower show at Fallowfield last week. The Horticultural Society, when started three years ago, had a membership of 25, but there are now over 200 members. Mr. J. M. McElroy, the Corporation tramway manager, opened the show, which included vegetables.

MEXICO: *Telegraphs and Telephones.*—Federal telegraphs in the State of Jalisco reach a total length of over 1,870 miles, and telephone lines in the hands of private companies cover 625 miles.

MONTREAL: *Public Lighting Contract.*—The Montreal Light, Heat, & Power Co. refuse to continue the public electric lighting at the prices of the old contract, which has just expired. The old schedule of charges was $60 per lamp in the city and $90 in certain of the outside districts. Mr. Lea Walbank, the manager of the company, has stated that the present bargain with the Council is an unfair one to the company, but he is willing for both sides to appoint experts to determine the price. He will, however, not negotiate except upon the basis of a ten year's agreement.

NAAS: *Central Ireland Electric Power Bill.*—At the weekly meeting of the Naas Board of Guardians last week Mr. John O'Connor, M.P., was publicly thanked for having secured the recommittal of the Central Ireland Electric Power Bill to the Committee of the House of Commons, which had previously rejected the measure. The Bill, it will be remembered, was passed and became law after Dublin and some other portions of the area originally scheduled had been struck out.

NEW ZEALAND: *Tramway Troubles.*—The special Court of Conciliation, appointed some weeks ago to deal with the dispute between the Auckland Tramway Co. and its employees, has made its award, says the *Australian Mining Standard.* All points claimed by the men are conceded, with one exception, viz., the stipulation that employees should not be required to work alongside "blacklegs," that term signifying two former employees who had refused to come out. On this point the Chairman said that these two men were entitled to their opinion, and it would be unfair to punish them for having the courage to act independently. The award was come to only on the casting vote of the Chairman. The Board direct that the recommendations shall take effect from September 1st, 1908, and shall continue in force until August 31st, 1910.

NORTHFLEET: *Electric Lighting.*—Supply is now given in Northfleet from the Gravesend municipal electricity works. The Gravesend Corporation was granted a provisional order for the district in 1905, but after a scheme was prepared, and an agreement entered into between the two parties, a resolution was passed abandoning the proposed supply. After much correspondence the Northfleet Council threatened a legal action to compel the fulfilment of the agreement, but this was not found necessary, and public lighting was inaugurated last week.

PERTH (Australia): *Electric Tramways.*—The aggregate gross receipts from January 1st to August 21st of the Perth Electric Tramways, Ltd., were £46,953, against £47,855 for the corresponding period of 1907.

SHANGHAI.—*Electric Tramways.*—Mr. A. Rose, Consul at Shanghai, reports that although the installation of 26 miles of electric tramway was expected to raise a storm of indignation among the natives of the coolie class, the innovation has passed almost without comment, and the cars are thronged with Chinese passengers.

SOUTH STONEHAM: *Electric Supply.*—The Rural District Council has agreed to allow the Southampton Corporation to lay mains in this district.

SOUTHEND: *Broken Trolley Wire.*—On Thursday one of the trolley wires of the Corporation tramways in the High Street broke and fell on a visitor, who was not, however, injured.

SOUTHPORT: *Bowling by Electric Light.*—In order to permit of bowling after dusk in the autumn and winter the Corporation have erected arc lamps at the Crowlands Bowling Green.

SUNDERLAND: *Electricity Supply.*—It is stated that the demand for electric power from the Corporation Works has shown no increase during the past six weeks, and that in consequence the reduced estimates prepared a short time ago are to be allowed to stand.

WEDNESBURY: *Strike.*—The strike at the works of the Patent Shaft and Axletree Co. has been ended on the men

Digitized by Google

agreeing to resume work, and the company to consider the alleged grievances. The company has all along refused to consider the matter until the men returned to work.

WIMBLEDON: *Street Lighting.*—The Electric Lighting Committee have decided upon the installation of a 220-volt 50-c.p. metal-filament lamp in each of the 1,045 lamp-posts in the borough, and the purchase of 155 metal-filament lamps for the purpose of stock, at an estimated cost of £286, while the estimated cost of the necessary alteration of wiring and fittings is £130 12s. 6d. A sub-committee has been appointed in the matter of a dispute between Jas. Howden & Co., Ltd., the contractors for the supply of a Zoelly turbine, &c., and the Electrical Engineer, respecting the amount of pipework included in their tender.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ASTLEY.—We understand that the Pilkington Colliery Co. (a new concern) intend putting down a considerable amount of electrical plant at the new pits they are now sinking at Astley Green, in southern Lancashire. The development of this new coalfield is expected to cost about a quarter of a million sterling.

BANBRIDGE (Co. Down).—The Council is to nominate a committee for the purpose of conducting negotiations in connection with an electric lighting scheme. The place has a very convenient source of power in the Upper Bann, which flows through the town.

BAVARIA.—In connection with the development of the water-power resources of Bavaria, the Bavarian Government offers prizes of £1,000, £750, and £500 for the three best sets of designs, including estimates of cost, for the works for the utilisation of the water-power of the "Walchensee." A general outline of the scheme, and the conditions of the competition, which is open to engineers of all nationalities, are to be obtained from the Bavarian State authorities on payment of a deposit of £1. The designs must be submitted on or before January 20th, 1909.

DENMARK.—The Town Council of Reykjavik (Iceland) has given to a Danish company a concession for supplying the town with electric light and gas. The concession is for a period of 25 years, and the plant is to be in working order by October 1st, 1909.

EAST INDIAN RAILWAY CO.—Tenders are invited for the supply and delivery of a 600-kw. three-phase alternator and of gas engine alternators and equipment, in accordance with specifications to be seen at the company's offices, Nicholas Lane, London, E.C. Tenders by September 16th. For each specification a fee of 21s. is charged (not returnable).

HASLINGDEN.—The Board of Guardians have been unable to come to terms with Rawtenstall for the supply of electricity for lighting the workhouse, and have decided to seek the sanction of the Local Government Board to generate their own electricity for lighting and power purposes.

INDIA.—In connection with the conversion of the Nilgiri Mountain Railway, the electric lighting of several towns will be undertaken.

ITALY (BARI).—The capital of the Società Elettrica Barese has been increased from £40,000 to £160,000 with a view to establishing a tramway service not only in Bari, but also to Carbonara, a town of about 12,000 inhabitants, some two miles distant.

LONDON: *London County Council.*—Tenders are invited for low-tension cables, &c., also high and low tension switchgear and motor generators. Tenders by September 8th.

SALFORD.—The Electricity Committee invite tenders for the supply and delivery of lighting and power feeder and distributor pillars. Specification and form of tender may be obtained on application at the office of Mr. Victor A. H. M'Cowen, Borough Electrical Engineer, Frederick Road, Pendleton. Tenders to be sent to the Chairman of the Electricity Committee by noon, Monday, September 14th, 1908.

STOKE-UPON-TRENT.—Tenders are invited for the supply, delivery, and erection of a water-cooling apparatus. Particulars from Mr. P. J. S. Tiddeman, the Electrical Engineer (fee, £1, returnable), and tenders to the Chairman of the Electricity Committee by September 8th.

WREXHAM.—An application is to be made to the Local Government Board for sanction to borrow £3,000 for extensions by the electricity department.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations, and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Buildings, Byward Street. Builders, John Green, Ltd., 12–14 Arthur Street, West, London Bridge.

S.E.—Business premises, Dockhead. Builders, Todd & Newman, 1A Stannard Road, Dalston, N.E.

Repairs, &c. (£1,500), to Christ Church, Blackfriars. Rev. E. J. Baker.

S.W.—New bank, King's Road, Chelsea, for London & County Banking Co., Lombard Street, E.C.

W.—Buildings, Devonshire Street. Builders, J. Jarvis & Sons, 253–255 Hackney Road, N.E.

Re-building 50 Welbeck Street, for Dr. Jefferson Faulder, 58 New Cavendish Street, W.

PROVINCES.

ABERDEEN.—Residence. Architects, Sutherland & George, 40 Union Terrace, Aberdeen.

ALDERSHOT.—Offices for Ind. Coope & Co., brewers, &c., Aldersgate, E.C.

BANGOR.—The Cathedral is to be fitted for electric lighting.

BIRMINGHAM.—Additions, The Crown, Snow Hill, and alterations, Britannia Inn, Sherbourne Road, and Stag's Head, Brearley Street, for Mitchells & Butlers, Ltd., brewers, Birmingham.

New factory in Hill Street for Birmingham Printers, Ltd.

Business premises, Aston Broak Street, for the Pitman Health Food Co.

BECKENHAM.—Additions, &c., to private residence (£1,400). Architect, G. St. Pierre Harris, 8 Laurence Pountney Hill, E.C.

BRIDGWATER.—Alterations (£8,500) to Municipal Buildings. W. T. Baker, Town Clerk.

BRISTOL.—Addition to Mission Hall. Surveyor, H. C. H. Tarr, Oxford Chambers, St. Stephen's Street, Bristol.

Chapel at Stapleton Workhouse.

BURNLEY.—Roman Catholic Church (£4,000) in Ivy Street.

BURTON LATIMER.—Factory for Standard Boot Co.

COWES (Isle of Wight).—Two houses. Builders: G. Ball & Son, Victoria Road, Cowes (Isle of Wight).

CREWE.—Wesleyan Sunday School (£1,800). Architect, F. P. Halsall, Victoria Chambers, Chapel Street, Southport.

DARTFORD.—Municipal buildings (sites under consideration). W. Kay, Clerk, District Council.

DUBLIN.—The Sligo Leitrim Asylum is to be fitted for electric lighting. Particulars from Messrs. A. Scott & Son, 49 Upper Sackville Street, Dublin, and tenders by September 15th.

DUNDEE.—Houses. Surveyor, T. M. Cappon, 32 Bank Street, Dundee.

FELIXSTOWE.—Additions and alterations to Post Office. Builders, T. Ward & Sons, Cliff Works, Felixstowe.

GELLIGAER.—Hospital (£7,800). Builders, Vodden & Lee, Gilfach-Bargoed (South Wales).

GLASGOW.—Masonic Temple, Vulcan Street. Alexander Grant, 631 Alexandra Parade

HERNE BAY.—Residence, Oxenden Park. Achitect, J. Huxtable, Highgate House, Station Road, Herne Bay.

HUDDERSFIELD.—Additions to Watergate Brewery.

Thirty houses. Surveyor, J. H. Hanson, Market Green, Cottingham, Hull.

LLANDUDNO.—Carnegie Library. Architect, G. A. Humphreys, Mostyn Estate Office, Llandudno.

MANCHESTER.—Extension of Cheetham Baths. City Architect, Henry Price.

Diocesan Church House, &c. (£50,000). Architect, John Brooke, 18 Exchange Street, Manchester.

MOTHERWELL.—Council Chamber in Brandon Street for Dalziel Parish Council.

NOTTINGHAM.—Offices for Sun Fire Office.

Re-building at Northgate for Shipstone & Sons, Ltd.

SALFORD.—Addition to Town Hall. Architect, J. B. Broadbent, 15 Cooper Street, Manchester.

SKIPTON (Yorks.).—Extensions, &c., Moor View Baths. Council Surveyor, John Mallinson.

SOUTHEND.—Additions to laundry, Eastwood Road, for Albany Laundry Co.

STOCKTON BROOK.—Wesleyan Church. Architect, Wm. Campbell, 2 Bagnall Street, Hanley.

UXBRIDGE.—Offices and factory. Surveyors, Thomas & Thomas, 191 Edgware Road, Paddington.

New Post Office (£4,000). Builder, George Jaggard, New Bushey, Watford.

WELLS (Somerset).—Laundry buildings for Somerset and Bath Asylum (£5,500). Builders, H. W. Pollard & Son, Monmouth Street, Bridgwater.

Digitized by Google

WEST HAM.—The Guardians invite tenders for supplies, including electrical fittings. Particulars from the Clerk, Union Road, Leytonstone, and tenders by September 17th.

WHITLEY BAY (Northumberland).—Pier, with pavilion, tea-rooms, &c. (£35,000). Architect, T. Brewer-Mather, Wallsend-on-Tyne.

WIGAN.—Four houses. Builder, A. Sharples, Essex Street, Wigan.

Additions to St. John's Parish Church, Dicconson Street. Rev. G. L. Carolan.

Additions, St. Catherine's Vicarage, Catherine Street. Rev. E. C. Poulter.

WIMBLEDON.—Six houses, Richmond Road. Surveyors, Daw, Seville & Co., 27 Chancery Lane, W.C.

Shops and flats, High Street, and residence, Clifton Road. Architects, Thomson & Pomeroy, 49 Hill Road, Wimbledon.

Residence and motor-house, Calonne Road. Surveyors, Boyton, Sons & Trevor, Wimbledon Park Station.

Eight Houses, Stuart Road, C. Barwell, The Elms, Morden.

Residence, Alan Road. Engineer, W. Allan Tanner, 16 Belvedere Gardens, Wimbledon.

Factory, Ashcombe Road. Estate Agent, L. S. Rogers, 86 Lancaster Road, West Norwood.

Residence, Murray Road. Architects, Niven & Wigglesworth, 104 High Holborn, W.C.

Extensions, Queen's Road Schools. Surveyor, Education Committe, Town Hall.

Miscellaneous

BEXLEY.—Tenders are invited for advertising on 12 double-deck cars. Particulars from Tramway Manager, Car Sheds, Bexley Heath.

BLACKPOOL.—The Tramway Committee invite tenders for 100 tons of steel rails, No. 4, B.S. section, 30 cwts. of fish-plates, 20 cwts. of tie-bars, and 300,000 hardwood paving blocks. Particulars from the Borough Engineer, and tenders by September 19th.

LEEDS.—The Tramways Committee is prepared to receive tenders for the disposal of 800 to 1,000 tons of old tramway rails. The rails are 7 in. by 7 in., and 95 lb. to 98 lb. per yard. Particulars from the General Manager.

MERTHYR TYDFIL.—Hills' Plymouth Co., Merthyr Tydfil, invite tenders for stores, including electrical appliances for the twelve months ending September 30th, 1909. Forms of tender may be obtained upon application in writing, enclosing stamped addressed foolscap envelope, and must be sent in not later than September 21st.

SOUTH AUSTRALIA.—Tenders are required by October 21st for power plant for charging accumulators for telegraph purposes at the General P.O., Adelaide.

SOUTHEND.—The Corporation contemplate the extension of the tramways from Leigh on to Hadleigh.

TASMANIA.—Tenders are required by the Postmaster-General's Department by November 2nd for material for accumulator equipment for telegraph purposes.

TURKEY.—H.M. Consul-General at Constantinople (Mr. H. C. A. Eyres) reports a call for tenders by the Turkish Ministry of Posts and Telegraphs for the supply of 1,360 insulators, and 15,000 Leclanché insulators. The date for the receipt of tenders is not given. Applicants should be ready to make a deposit of 10 per cent. or to produce an adequate guarantee legalised by the Constantinople Chamber of Commerce. British firms cannot hope to do business except through a local agent.

WESTERN AUSTRALIA.—Tenders are required by October 6th for the supply of telegraph and telephone material. Tenderers must state the country in which the articles tendered for have been made or produced, and in the case of manufactured articles where the material has been made or produced. Tenders must include Customs duty, if any. Copies of specifications, general conditions, and schedules of tender may be obtained at the General Post Office, Perth (where sealed patterns can be seen), and at the General Post Offices, Adelaide, Melbourne, Sydney, Brisbane, Hobart, and the Commonwealth Office, London.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Municipal Tramways Trust, Adelaide, has accepted the tender of Messrs. Noyes Bros., Prop., Ltd., on behalf of the British Westinghouse Co., for the supply, delivery, and erection of motor equipments and car wiring, the total amount of their contract being £12,242 14s. 2d.; also the tender of Messrs. Geo. Wills & Co., on behalf of the Australian General Electric Co., for the supply of certain spares, the total amount of this contract being £425.

BOLTON.—For the supply of cylinder oils, the tender of Messrs. Waring & Co., has been accepted.

BRIDLINGTON.—The Council has decided to insure two superheaters with the National Boiler & General Insurance Co., at an annual premium of £1 each.

COVENTRY.—A tender for the electric lighting of St. Michael's Church, has been accepted.

DENNY.—The following tenders have been received for cables in connection with the electric lighting scheme:—Lowdon Bros., £923; British Insulated & Helsby Cables Co. (accepted), £764; Johnson & Phillips, £851; Callenders' Cable & Construction Co., £835.

DUBLIN.—Thirty-four Tierney & Malone automatic point controllers are to be introduced in the Corporation's lines. Three of these automatic controllers have been in use for the past four months, with such good results that the Corporation has placed an order with Messrs. Brecknell, Munro & Rogers for the equipment of the system.

ECCLES.—The Electricity Committee have accepted the tender of Messrs. Ferranti, Ltd., for the supply and erection of a switch panel, and that of Messrs. John Spencer, Ltd. (Wednesbury), for circulating water piping at the electricity works.

GLASGOW.—Messrs. Johnson & Phillips, Ltd., have received an order (extension) from the Clyde Navigation, for Rothesay Dock for insulators.

HANLEY.—The tenders of the British Insulated & Helsby Cables, Ltd., for three-core low-tension distributing cable and high-tension feeder cable have been accepted at £257 and £18 respectively.

HULL.—The Electric Light Committee has accepted the tender of Messrs. Korting Bros., Ltd., for pipe-work, at £573.

LOCHGELLY.—The Lochgelly Iron & Coal Co., have placed an order with Messrs. Johnson & Phillips, for the supply and erection of shaft and in-bye cables for their Lochgelly pits.

LONDON.—The following tenders were received for the electric wiring of Messrs. Selfridge's new store in Oxford Street:—Malcolm & Allan, Glasgow (accepted), £5,261; G. Harland Bowden & Co., £5,620; Foote & Milne, £5,923; Lund Bros. & Co., £5,990; Tyler & Freeman, £6,466; Higgins & Griffiths, £6,478; Duncan, Watson, & Co., £6,874; Waring & Withers, £7,173; Electrical Co., £7,200; Edmundson's Electricity Corporation, £7,733; Blackburn, Starling, & Co., £8,074; Rawlings Bros., £8,681; Drake & Gorham, £8,706; Donnison, Sillem & Co., £8,800; Rashleigh Phipps & Co., £9,157; Belshaw & Co., £9,634.

MAIDSTONE.—A demi-car for working upon the Tovil route is to be purchased for £600.

MANCHESTER.—The Electricity Committee have placed with Veritys, Ltd., the order for ½, 2, 7, and 10-h.p. motors of the "Aston" interpole type, and for ½, 1, 2, 3, and 7-h.p. improved "Aston" starters, both contracts being for two years.

TADCASTER.—A tender by the Tadcaster Electricity Supply Co., to light the streets with 13 lamps, from September 1st, 1908, until April 30th, 1909, for £40, has been accepted.

TIVERTON.—The Bradninch Electric Light Co. have offered to light the village of Bradninch, in the Tiverton rural district, at £25 per annum.

WIGAN.—The Electricity Committee has accepted the tender of the Pemberton Colliery Co., Ltd., for the supply of 6,000 tons of Wigan slack at 7s. 6d. per ton.

WIMBLEDON.—The Electric Lighting Committee has accepted the following tenders:—For the supply of bricks required in connection with the foundations for the 1,000-kw. turbo-alternator now being constructed, Sussex Brick & Tile Co., Ltd, 9in. square, 32s. per 1,000, and 9-in. radiated bricks, at 48s. 6d. per 1,000; for the supply of steel girder work in connection with foundations, Dorman, Long & Co., £41 16s. 6d.

COMPANIES' MEETINGS AND REPORTS

BLACKPOOL & FLEETWOOD TRAMROAD CO.—The half-yearly meeting was held at Fleetwood on Thursday, when the report and accounts given in our issue for August 15th were adopted. The Chairman, Mr. G. Richardson, said that the present trade depression was showing itself in the current half-year's accounts, the receipts for the first six weeks being slightly lower than those for the corresponding period of last year.

DUMBARTON BURGH & COUNTY TRAMWAYS CO.—The report states that the accounts show a profit of £3,870. A dividend of 6 per cent. per annum is recommended upon the preference shares, carrying forward £1,730.

LAWES CHEMICAL MANURE CO.—At the annual meeting on Thursday, it was stated that electric motors have been installed at the works, power being obtained from the Barking Council on fairly advantageous terms. The motors were working well, and a saving had thus been effected. The cost had been charged to revenue since the motors took the place of machinery already in existence, and it was the policy of the company to replace and maintain machinery and plant out of revenue.

SALINAS OF MEXICO.—Speaking at the annual meeting of this company on Thursday, Col. G. E. Church, the chairman, said that their neighbours, the Benito Juarez Mining Co., are about to erect an electric power plant near the Salinas Railway station on ground which was rented to them for the purpose for a nominal consideration, but on condition that they furnish the company with electric power at cost price. This should be of much benefit, as their wood fuel was giving out, and the electric power will enable them to produce table salt cheaper.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wirebars, net. c.i.f. port of arrival, quoted on Tuesday night was £63 to £63 10s. per ton (last week £62 10s. to £63 per ton).

ARMORDUCT MANUFACTURING CO.—The annual Staff Outing of the company took place on Saturday, August 22nd. The London Staff, together with the Branch Managers, Agents, and friends, went up the river in the launch *Royal Thames*, from Molesey Lock to Windsor. The party returned after spending an hour in Windsor. The evening was spent at Tagg's Island Hotel.

BOILER AND STEAM PIPE COVERINGS.—Messrs. Conrad Lauer & Co. have started business as boiler and steam pipe coverers at 65 Euston Road, London, N.W. Mr. Conrad Lauer has been associated with Messrs. A. Haacke & Co., of Homerton, for the last 25 years. Mr. George Cross has also left the employment of Messrs. A. Haacke & Co., Ltd., Homerton, to join Messrs. Conrad Lauer & Co.

BROCKIE PELL ARC LAMP CO.—We are informed that the Brockie Pell Arc Lamp Co., who have recently moved their works to Wimbledon, S.W., have just executed a large order for workshop lighting in Lancashire, and are now engaged on an order for three hundred open type double carbon arc lamps for one of the leading railway companies.

ECCO BATTERY & ELECTRICAL CO.—Owing to the continual growth of this business, and to the necessity for being within easy reach of the City, a factory has been built and equipped at Invicta Works, Bow Common Lane, Bow, London, E.

ELECTRICAL APPARATUS IN TURKEY.—H.M. Consul at Smyrna states that electrical appliances which have hitherto been strictly excluded from Turkey, are now being gradually introduced.

ELECTRICAL MACHINERY MARKET IN SPAIN.—A consular report states that North of Spain buyers are so accustomed to deal with German and Swiss firms only in the electrical machinery trade that it is difficult to make them believe that similar goods are manufactured in the United Kingdom, and the only practical way for British firms to secure any share of this trade is to combine to open branches in Spain carrying representative stocks and with a staff of technical experts who can speak Spanish. The electrical machinery and motor trades in Spain possess considerable potentialities, but British industry must adopt aggressive tactics to derive advantage from them.

PLANT FOR SALE.—At the Victoria Pit, Heckmondwike, on Friday, September 18th, will be sold an electric winding plant specially designed and erected by Messrs. Ernest Scott & Mountain, Ltd., of Newcastle-on-Tyne. The plant includes a four-pole 80-kw. dynamo, a 30-h.p. motor, together with switchboard, starting and reversing switches, &c. The auctioneers are Messrs. Hollis & Webb, 3 Park Place, Leeds.

SIMPLEX CONDUITS.—A new department has been opened at the Birmingham manufactory of Simplex Conduits, Ltd., for the exploitation of that firm's electrical signs. This part of their business has hitherto been carried out by sign-writers and sign-makers, whereas, strictly speaking, it comes within the scope of the electrical contractor. The company therefore propose to place the latter in a much more advantageous position in the future.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A general meeting of the Mevagissy Electric Lighting Co. will be held at the Town Hall, Mevagissy, Cornwall, on Friday October 2nd, at 3.30 p.m., to receive the liquidator's account of the winding-up.

At the Edinburgh Sheriff's Court last week the examination of J. A. Wilson, Electrical Engineer, of Kilmarnock, took place. The statement of affairs showed liabilities amounting to £2,450, and assets to £310. The debtor attributed a considerable portion of his losses to the fact that he had neglected his mill furnishing business in order to develop the electric lighting business, which had been a failure. The examination was concluded.

Creditors of the Commercial Electro-Chemical Analysis Co. are requested to send particulars of their claims to the liquidator, Mr. A. C. Roberts, 9 and 10 Pancras Lane, London, E.C., not later than September 30th.

Mr. Edgar Musgrave, of Craven Bank Chambers, Bradford, has been appointed trustee in the bankruptcy of W. T. Garnett, trading as W. T. Garnett's Cable Co., Barkerend Mills, Bradford.

DISSOLUTION OF PARTNERSHIP.—The partnership between William Rodger and Joseph Harris, carrying on business as consulting and electrical engineers, 10 Gardner Street, Glasgow, has been dissolved. Joseph Harris continues.

NEW PUBLICATION

"The Principles of Alternating Currents." By Edgar T. Larner. (London: Crosby Lockwood & Son.) 3s. 6d.

MISCELLANEOUS CITY NOTES

BRITISH INSULATED & HELSBY CABLES.—The transfer books will be closed from the 5th to the 12th inst., both days inclusive, for the preparation of warrants for dividend on the ordinary shares of this company. The warrants will be paid on the 16th inst.

CROSSLEY BROS.—Owing to depression in trade, and the unsettled outlook, the directors consider it undesirable to pay a higher dividend than 5 per cent. per annum for the half-year to June 30th.

DUMBARTON BURGH & COUNTY TRAMWAYS CO.—The result of the working of this company from February this year, when the lines were first put in operation, until July 31st, is that it has earned sufficient to pay its preference dividend and to carry forward £1,780.

GENERAL ELECTRIC CO. (RUSSIA).—The accounts for the past year show a net profit of 511,470 roubles, against 439,050 roubles for the previous year. A dividend of 4 per cent. is recommended, against 3 per cent. for the previous twelve months.

METROPOLITAN ELECTRIC TRAMWAYS.—The receipts from January 1st, 1908, to date amount to £194,500, an increase of £37,167 over those for the corresponding period of 1907.

MEXICAN LIGHT & POWER CO.—Some attention is being drawn to the merits of this company's stock, mainly by reason of a little squabble between a morning and a financial paper as to who first "discovered" this stock. It appears that since April 29th the company's common stock has risen 34½ points, and since August 8th the seven per cent. convertible cumulative preference stock has risen 4½ points.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—Warrants for interim dividend on the company's 7 per cent. cumulative preference shares for the half-year ended June 30th, 1908 (payable on August 31st), have been posted.

TYNESIDE TRAMWAYS CO.—The total receipts to date from the commencement of the current half-year amount to £3,615, against £3,937 for the corresponding period of last year.

NEW COMPANIES

G. DAVENPORT & CO.—This company was registered on August 19th, with a capital of £7,000 in £1 shares, to adopt an agreement with G. Davenport for the acquisition of the business carried on by him at 95 Clerkenwell Road, E.C., as "G. Davenport & Co.," and to carry on the business of manufacturers and importers of and agents for goods in connection with motors, motor-cars and carriages, and horological, mechanical, and electrical novelties, &c. The subscribers are G. Davenport and J. Davie. Private company. G. Davenport is governor director for life. Remuneration, £400 per annum when profits available for dividend are less than 10 per cent., and £500 per annum when more than 10 per cent. of such profits are available. Registered office: 95 Clerkenwell Road, E.C.

DYNAMO ELECTRIC CAR TRANSMISSION SYNDICATE.—This company has been registered with a capital of £2,000 in £1 shares, to adopt an agreement between F. Plutte and A. P. Wright on the one hand, and W. O. Clark on the other, for the purchase of certain patents, and to carry on the business indicated by the title. The first directors are A. P. Wright and A. F. H. Hotopf. Registered offices, 47 New Broad Street, London, E.C.

ELECTRIC LAUNDRY, DYEING & CLEANING WORKS.—This company was registered on August 20th, with a capital of £5,000 in £1 shares (3,500 6 per cent. cumulative preference), to acquire the business of a launderer, &c., carried on by C. J. Robbins at the Electric Laundry, Sydenham Road, West Hartlepool. The subscribers are C. J. Robbins and Miss L. J. Robbins. Private company. Table "A" mainly applies. Registered office: Sydenham Road, West Hartlepool.

LIND & CO.—This company was registered on August 21st with a capital of £5,000 in £1 shares, to acquire the business of an electrical manufacturers' agent, general electrician, and contractor carried on by A. L. Lind & G. St. J. Wood, at 37 Moorfields, Liverpool, as "Lind & Co." The subscribers include A. L. Lind, 5 Cecil Road, Prenton, Cheshire, electrical engineer, and G. St. J. Wood, 4 Buckingham Avenue, Claughton, Birkenhead, electrical engineer. Private company. The first directors are A. L. Lind, G. St. J. Wood, and J. G. Wilson. Registered office:—37 Moorfields, Liverpool.

COMPANY MORTGAGES

ACKROYD & BEST.—Particulars of £15,000 debentures created by resolution of March 3rd, 1904, and secured by a trust deed dated July 2nd, 1904 (supplemental to deeds of 1900 and 1903), have been filed pursuant to Section 10 (3) of the Companies Act, 1907, the amount of the present issue being £500. Property charged—the company's undertaking and property, present and future, including uncalled capital. Trustees—C. T. Naylor, of Alresford, Hants, and J. P. Humble, of Wortley, Leeds.

ALUMINIUM CORPORATION.—Memorandum of equitable charge, dated July 21st, 1908, to secure an unspecified amount

Digitized by Google

(stamped to cover £10,000), has been registered. Property charged—Property at Dolgarrog, Carnarvon and Wallsend-on-Tyne, Northumberland. Holders—Lloyds Bank, Ltd., 72 Lombard Street, E.C.

BRITISH ALUMINIUM CO.—Trust deed, dated July 28th, 1908, to secure £1,000,000 debenture stock, has been registered. Property charged :—Certain freehold, leasehold, and other property, present or future, except uncalled capital. Trustees :—Trustees' Executors and Securities Insurance Corporation, Ltd., Winchester House, E.C.

CITY OF LONDON ELECTRIC LIGHTING CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Trust deed dated February 26th, securing £400,000.

DURHAM COLLIERIES ELECTRIC POWER CO.—Amended return, filed August 10th, of a charge dated July 15th, 1908, states that the holders thereof are the Trustees Executors & Securities Insurance Corporation, Ltd., of Winchester House, E.C. The word "Securities" was omitted from the previous return, which read "Trustees and Executors Insurance Corporation, Ltd."

HORSFALL DESTRUCTOR CO.—A memorandum of satisfaction in full of debenture, dated April 22nd, 1908, securing £2,000 (by way of indemnity), has been filed.

P. & W. MacLELLAN.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—mortgage, dated February 22nd, 1900, securing £150,000 debentures.

OXFORD ELECTRIC CO.—A statement of the total amount outstanding on July 1st, in respect of mortgages and charges created prior to that date, and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Trust deed, dated July 21st, 1897, securing £50,000.

PACIFIC & EUROPEAN TELEGRAPH CO.—A statement of the total amount outstanding on July 1st, in respect of mortgages and charges created prior to that date, and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars—Debentures, dated November 17th, 1892, securing £99,400 (£100,000 authorised).

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—Mortgage, dated February 5th, 1907, stamped to cover £80,000, was registered on August 1st, 1908, pursuant to order of Court. Property charged—Certain freehold hereditaments near Denmark Hill, and all purchase-money payable to mortgagors in the event of any sale or transfer of undertaking or part thereof. Holders—National Provincial Bank of England, Ltd., 112 Bishopsgate Street Within, E.C.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The *Financial Times* contains the following particulars of a trust deed, dated July 30th, 1908, which has been registered by the Underground Electric Railways Co. of London. The deed is to secure (1) prior lien bonds not exceeding £1,000,000 (unless same be increased as provided in conditions endorsed thereon to £1,250,000); (2) 4½ per cent. bonds of 1933, securing not more than £3,000,000; and (3) 6 per cent. income bonds, securing not more than £5,200,000 (all created by resolution of July 30th, 1908). The property charged is (*a*) stocks and shares of various electric railway and tramway companies, amounting in all to £11,079,990 (known as the "appropriated assets"); (*b*) shares in three tube railways, amounting in all to £3,500,000; (*c*) freehold power-house and other buildings at Chelsea, with plant, &c., thereon, cable subway therefrom to near Earl's Court Station, &c.; and (*d*) rights under various contracts. The trustees are the London and Westminster Bank, Ltd., Lothbury, E.C. Commissions, discounts, &c. :—(*a*) For underwriting £1,000,000 prior lien bonds, £25,000, with ½ per cent. brokerage on nominal value; (*b*) for procuring or agreeing to procure subscriptions for said issue of £1,000,000 prior lien bonds, brokerage of ¼ per cent. on amounts allotted in response to such applications from shareholders and holders of profit-sharing secured notes as are handed in by brokers; (*c*) under the scheme of arrangement holders of the £7,000,000 profit-sharing secured notes exchange their notes as to 40 per cent. of their nominal value into 4½ per cent. bonds of 1933 at par, and as to 70 per cent. of their nominal value into 6 per cent. income bonds at par, the exchange taking place as from December 1st, 1907; (*d*) the company has agreed to sell 4½ per cent. bonds of 1933 and 6 per cent. income bonds at the rate of £300, and accrued interest on the 4½ per cent. bonds for £200 (nominal) of the 4½ per cent. bonds and £300 (nominal) of the income bonds (taken together); the total amount which may thus be sold is limited to £200,000 (nominal) of 4½ per cent. bonds of 1933 and £300,000 (nominal) of income bonds.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—A trust deed, August 4th, for securing a series of prior lien bonds not to exceed £1,000,000, together with the power to increase under certain conditions to £1,250,000; also to secure a series of four-and-a-half per cent. bonds (1933) not to exceed £3,000,000; and also to secure a series of six per cent. income bonds not to exceed £5,200,000, has been registered; trustee: London & Westminster Bank, Limited, Lothbury, E.C. (shares and stock, freehold land, buildings, and power-house situate at Lots Road, Chelsea, together with rights and interest of the company in specified contracts).

VENEZUELA TELEPHONE & ELECTRICAL APPLIANCES CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars :—Mortgages or charges, dated July 28th, 1890, and April 7th, 1893, securing £88,500.

WEST COAST OF AMERICA TELEGRAPH CO.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under section 14 of the Companies Act, 1900, has been filed pursuant to section 12 of the Companies Act, 1907. Particulars :—£150,000 four per cent. debentures and £20,000 four per cent. income bonds, dated April 28th, 1897.

Telegraph Traffic and Movements of Cable Ships.—The Kwandang-Menado cable will no doubt soon be restored now that the cable-repairing steamer has got off the sandbank without suffering damage. The re-establishment of telegraphic communication with Venezuela may either be as far off as ever or nearer consummation, for the Venezuelan Courts have condemned the French Cable Co. owning the cables to pay a fine of $5,000,000, or £1,000,000, and possibly more, for having taken part in or assisted the Matos revolution. This may bring matters to a head, and, as the Dutch Government are preparing to take a stand against President Castro by reason of the prohibition of shipping between Curaçao and Venezuela, they will no doubt receive the moral support of other European nations. A new cable is being laid between Chafarinas, North Morocco, and Nemours, in Algeria, which will be employed for traffic passing between Spain and her African possessions. The German Government are making determined and successful efforts to free themselves from dependence on the telegraph lines of other countries, and are about to subsidise a cable direct from Emden to the island of Teneriffe, and thence to the German colonies in West Africa and South America. The company laying the cable is called the Deutsch Süd-amerikanische Telegraphengesellschaft, and was founded in Cologne by the same syndicate which founded the German Atlantic and other German submarine telegraph companies. It is an entirely independent company from the German Atlantic Co. The cable is being manufactured by the Norddeutsche Seekabelwerk in Nordenham a. d. Weser. The capital of the company is fixed for the present at £1,350,000. The cable between Cadiz and Teneriffe still remains down, as well as the cable between Las Palmas and Arecife. The Port Arthur-Chefoo cable still remains closed to service, and has been in this condition since March 9th, 1904. The cable between Kotonow and Lagos, which was only recently repaired, is again in trouble, having ceased working on 29th ulto. Communication between Bagdad and Bassorah was down on 29th ult., while the cable between Paramaribo and Cayenne, French Guiana, stopped service on August 31st.

Wireless Telegraphy.—It is stated in a British Consular Report that the Marconi station at San Cataldo is still doing service, but is little used for commercial purposes, trade with Montenegro not being important. In a report from the Consul-General in Mexico, it is mentioned that the new wireless telegraphic station between San José del Cabo and Mazatlan will be working very shortly, thus connecting La Paz with the rest of the world, and greatly facilitating all business operations.

According to the daily papers, passengers by the Dover-Ostend mail steamer may now send wireless telegrams at the rate of three half-pence a word for the first ten words, and a penny for each subsequent word.

A correspondent of *The Times*, quoting from an article in the *Dresdener Nachrichten*, with reference to the recent experiments with wireless telegraphy and army balloons, writes that experiments carried out in Germany have shown that an insulating appliance can be fitted, by which means the danger of explosion is, if not entirely excluded, at least reduced to a minimum. The fact has been established, moreover, that messages can be transmitted from balloons even though earth connection is absent. The experiments made in conjunction with the wireless station at Nauen were eminently satisfactory, and they are being continued. On the whole, the results achieved may be described as exceptionally favourable.

A note in a recent issue of the *Yorkshire Post* states that Dr. Polis, Director of the Meteorological Observatory at Aix-la-Chapelle, is continuing his experiments in transmitting meteorological observations at sea between New York and England by means of wireless telegraphy. Dr. Polis, it is said, has succeeded in receiving weather reports from America at a distance of eight hundred nautical miles from the American coast, while reports from Europe were actually picked up at a distance of twelve hundred nautical miles from the English coast.

SUMMARY

THE coroner's inquest concerning the airship explosion at the Franco-British Exhibition was concluded on Monday. From the evidence it appears that the explosion was due to a mixture of hydrogen and air, near the mouth of the gas bag, being ignited from a spark on the switch of a fan which was being used to drive some air into the balloon, in order to make up for some of the hydrogen which had escaped. (Page 381.)

THE first section of the Haslingden Corporation tramway system, which consists of about a mile and a half of single track extending from Haslingden to Accrington, was opened on Saturday last. The overhead work has been carried out on the Pringle "tangential" system. Both cars and current are being supplied at 7d. per car mile by the Accrington Corporation pending the installation of the steam generating set at the Haslingden refuse destructor station. The rails are welded by the Thermit process. An innovation in the way of provision for ventilation of the tramway poles has been introduced. (Page 381.)

A NEW type of single-phase motor, the invention of Mr. H. C. E. JACOBY, has just been put on the market. A special winding is employed to reduce commutation difficulties to a minimum. Although the motor has normally a series characteristic, it is claimed that the effect of a shunt characteristic can be obtained by shifting the brushes automatically by means of a centrifugal governor. For variable speed driving it is arranged that the brush-gear can be rotated by hand. We are informed that the motor develops a starting torque of over twice the normal full load value, and runs sparklessly at all speeds. In the construction of the automatic governing arrangement, use is made of the fact that the brushes tend to rotate with the commutator, and at normal speed the governor just balances this tendency. (Page 383.)

WE have received some further information from Dr. LEE DE FOREST with regard to the wireless telephone station which will be erected shortly in New York. It is hoped that the new station will be in operation by November 1st, and that before two years have elapsed, a wireless telegraph service between New York and Paris will have been established. Dr. DE FOREST does not expect to realise wireless telephonic communication between New York and Paris for five years or more. (Page 384.)

ON Thursday Mr. DUGALD CLERK delivered the Presidential Address to the Engineering Section of the British Association for the Advancement of Science, in Dublin, and dealt with the history and evolution of the study of thermo-dynamics, showing how, although large numbers of economical engines were certainly

Digitized by Google

constructed fifty years ago, the appreciation of the true theory of thermo-dynamics was much more recent.

Mr. GERALD STONEY contributed a Paper on Recent Advances in Steam Turbines, dealing also with the electrical generators coupled to them. He had found that compensating winding gave better commutation either than auxiliary poles or commutating poles and compensating winding combined. This winding is generally concentrated on the pole-pieces, and, he said, is given 2 to 2½ times the ampere-turns of the armature. In the case of alternators, the staying of the end windings had been receiving much atention during late years, to prevent breakdowns in the event of short circuits. For the design of the rotor he preferred salient poles to the barrel type. Referring to the importance of a high vacuum, Mr. Stoney said that 1 in. of vacuum is equivalent to 4 to 5 per cent. of the steam consumption. Reference was also made to the Parsons and Law method of compounding alternators.

A report by the Electrical Standards Committee was submitted, giving particulars of tests made to ascertain the secular changes in mercury and wire standards at the National Physical Laboratory, and containing also specifications for the international ohm and ampere, and the preparation of the Weston cadmium cell to serve as a basis for discussion at the International Congress to be held next month. In the Physical Section on Friday, the subject of absorbing interest was the radio-active elements, particularly a discussion on SIR WILLIAM RAMSAY'S question, "Do the radio-active gases (emanations) belong to the Argon series?" and a Paper by SIR JAMES DEWAR, to which we shall refer in our next issue, on measurements of the amount of helium evolved from radium.

On Monday three Papers were discussed simultaneously in the Engineering Section. Capt. H. R. SANKEY described the scheme for the utilisation of peat in Ireland, not only for making charcoal and recovering sulphate of ammonia and other bye-products, but also for making gas. Mr. CROSSLEY and Mr. RIGBY, of Crossley Bros., who have the contract for the gas engine plant in connection with this scheme, contributed to the discussion, commenting also on certain points in the other two Papers. These Papers were on producer gas, by Mr. J. E. DOWSON, and on suction gas plant by Mr. P. W. ROBSON. Mr. Dowson compared the relative advantages and applications of pressure gas plant and suction plant. The suction plant costs less and occupies less ground-space, but the gas is not so strong as in the older form of pressure plant. The fuel and water consumption and the labour are, according to Mr. Dowson, the same in both cases. Mr. Robson's Paper put forward figures and arguments with a view to proving the superiority of suction gas plants to electric power. He outlined the principal upon which these plants work, referred to the difficulty experienced owing to the formation of tar in the pipes and passages when bituminous fuels are used, and suggested a method of eliminating this evil upon which experiments are now being made. Mr. Crossley and Mr. Rigby both said that their firm's fan separator was quite sufficient to eliminate this trouble without seeking for other methods.—Prof. ERNEST WILSON described some observations he had made with light aluminium alloys which showed in some cases a considerable falling off in conductivity with age. (Pages 385-397.)

THE Manufacturers' Association of Great Britain has been successful in securing several important reductions in the import tariffs upon electrical machinery into Australia. A 25 per cent. duty upon dynamo electric machines up to the capacity of 200 h.p., static transformers and induction coils, and electric fans, has been reduced to 20 per cent.; whilst electric fittings are to be admitted free, instead of under a duty of 20 per cent. (Page 397.)

A SINGLE-PHASE lift motor with some interesting features has been brought out recently by an American firm. The motor is a commutator motor working on the repulsion principle, and provided with a device, operated by centrifugal action, to short-circuit the armature when the latter has attained the synchronous speed. The starting torque of the motor is about 400 per cent. of the normal full load torque, and is obtained with about 200 per cent. of full load current. (Page 398.)

UNDER ELECTROMETALLURGY AND ELECTROCHEMISTRY we describe a new type of primary cell. The negative element consists of a number of carbon rods surrounded with an acid solution of lead tetrachloride; the positive element is an amalgamated zinc cylinder which is contained in a porous cell filled with dilute hydrochloric acid or ammonium chloride. The cell resembles the Daniell cell, in that depolarisation is rapid; but it has an E.M.F. of about the same as the Leclanché, and a lower resistance. (Page 399.)

THE output of the Aberdeen electricity undertaking for the year ended July 21st showed an increase of 309,529 units over the preceding year. Owing to the increase in the cost of coal an extra sum of £2,270 is shown in the fuel item.—For the year ended March 31st, 1908, the accounts of the Barrow-in-Furness electricity undertaking show a deficit of £791, after meeting capital charges.—A surcharge has been made in connection with the expenses of the Belfast representatives to the annual convention of the Incorporated Municipal Electrical Association.—Successful experiments have been carried out by the Birmingham Corporation with the Maley electromagnetic track brake; in one of the experiments a car was allowed to run backwards down a hill, and was pulled up without difficulty by the brake.—The accounts of the Bradford tramways department show a balance of £17,238 after meeting capital charges. The whole of this has been carried to the reserve and renewals accounts.—The jolting of the tramcars in Burslem was said, at a Council meeting, to cause pictures to fall from the walls of houses along the route; no information was given as to the nature of the walls or how they were plugged.—An agreement has been drawn up between the Felixstowe Council and the Suffolk Electricity Supply Co. for the purchase of the company's undertaking at £8,000.—A suggestion that trolley omnibuses should be used in Hastings is to receive consideration.—For the 35 weeks from January 1st to August 29th, the receipts of the Liverpool tramways show a falling off of several thousand pounds, and the passengers carried by nearly two millions.—It is understood that the deputation of the Manchester Tramways Committee which recently visited the Continent, will recommend the adoption of trolley omnibuses in certain suburbs. (Page 403.)

THE Accrington Council has received sanction to a loan of £7,500. A suction gas plant is to be installed at Clacton, and a 1,000-kw. steam turbo-generating set at Johannesburg. Extensions of plant are also to be carried out at Cheltenham and Colchester. (Page 406.)

THE accounts of the Yorkshire Electric Power Co. for the June half-year show a net profit of £363 after payment of mortgage interest. There was a loss of £139 in the corresponding period of last year. At the meeting of the Sheffield Gas Co. some comparisons were made between the amount of rates paid by the municipal trading departments and the company in relation to the capital and profits. It was urged that either the gas company was paying too much, or the municipal departments far too little. A dividend of 8 per cent. per annum, for the June half-year is announced upon the ordinary shares of the British Insulated & Helsby Cables Co. An amalgamation is announced between the Mexican Light & Power Co. and the Mexican Tramways Co. (Page 408.)

A NEW arrangement of boosters and balancers is suggested by Messrs. W. FENNELL and W. P. PERRY for improving the pressure regulation on continuous-current three-wire systems. (Page 411.)

FROM among the Patent Specifications published on Thursday last, the following have been selected and are abstracted in this issue: A system of speed control for marine propulsion with alternating current motors, by H. A. MAVOR and W. B. HIRD; improvements in an automatic telephone exchange, by SIEMENS BROS. & Co.; a method of manufacturing the active plates of alkaline accumulators, by W. FENNELL and W. P. PERRY; an arrangement for automatically isolating a section of an alternating-current distribution system, when a fault develops in that section, by the BRITISH THOMSON-HOUSTON Co.; a resilient glass support for metal filaments, by T. W. LOWDEN; an improvement in the design of single-phase commutator motors whereby certain of the interpoles or auxiliary windings are omitted, by the ALLGEMEINE ELEKTRICITÄTS GES.; a method of preventing the operation of the contactors in a multiple unit control system from being influenced by variations of the line pressure, by the BRITISH THOMSON-HOUSTON Co.; an electromagnetic device for limiting the speed of series motors, by the ALLGEMEINE ELEKTRICITÄTS GES.; the design of small transformers for metal filament lamps, by H. W. TURNER; lead fuses containing an arc-extinguishing composition, by F. POOLEY and W. R. MACDONALD; and a multiple-circuit wave winding for single-phase commutator motors, enabling more than two sets of brushes to be employed, by the BRITISH THOMSON-HOUSTON Co. The only patent of electrical interest which expires during the current week is one by F. H. W. HIGGINS for a non-resonant telephone receiver, a special construction of the diaphragm, and a means of ventilating call-boxes. (Pages 411 and 412.)

RIGID rules are enforced with regard to the use of electricity in mines, and these are supplemented by regular inspections by officials of the Home Office, who possess very definite technical knowledge. In positions where gas might be expected, motors must have their current-carrying parts, starters, and terminals completely enclosed in flame-tight cases, and the same applies to fuses and switches. It is interesting to contrast this with the state of affairs which obtained in the tent at the Franco-British Exhibition, where a gas-bag containing nearly 10,000 cubic feet of hydrogen was stored. In this tent no exceptional precautions seem to have been taken with regard to the wiring, except the insertion of some so-called "safety" plugs, which in all probability rather add to the risk than diminish it. But a graver offence still against the interests of public safety was one which caused the unfortunate disaster resulting in the deaths of three people, and injuries to others, and might very well have resulted in a regular catastrophe involving the fate of a large portion of the Exhibition and the public who were visiting it. An ordinary fan motor was used to force air into the gas bag of the balloon to take the place of some of the hydrogen which had escaped by leakage. Although it appears that this fan was an alternating-current one, and that, therefore, there was no commutator at which sparking could occur, at the base of the fan was a lever switch of the usual type, the handle of which passed through an open slot. Those who have used these fans know well the bright spark which occurs on switching off, which is quite visible through the opening in the base. There can be little doubt that the explosion was occasioned by the attendant who was using this fan switching off when the pressure in the balloon equalised the upward pressure caused by the fan, and the gas started diffusing into the tent. We trust that some vigorous action will be taken by the authorities to fix the blame for this occurrence on those who are really responsible for allowing such dangerous proceedings to be carried out in the centre of an Exhibition in London. It is no excuse to say that the owner of the balloon or his assistants were ignorant of the danger, as was evidently the case. It should have been somebody's duty to have ascertained that these men were ignorant before permission was given to them to handle a large balloon in such a position. We trust that the matter will not rest as it stands with the mild verdict of the coroner's jury, but that definite action will be taken in the interests of public safety.

IN an article on page 367 of last week's issue we described some experiments connected with the so-called overshooting of tungsten filament lamps. The difference between the behaviour of the metal and the carbon filament lamp was there attributed by the experimenters to the fact that, whereas the resistance of the metal filament increases with increasing temperature, the resistance of the carbon filament decreases. In an editorial note the *Electrical World* points out, however, that this fact by itself is not sufficient to explain all the phenomena noticed. The overshooting of current is only what might be expected, and exists in all metal filament lamps; but the overshooting in candle-power is more difficult to explain. There are two theories, our contemporary says, that naturally suggest themselves, and it is rightly pointed out that one of these is hardly tenable. The more probable explanation of the two that are advanced is that the cold tungsten filament absorbs and occludes certain gaseous substances from the low-pressure space within the chamber; that by virtue of the presence of these gases the filament shines more brightly when first brought suddenly to incandescence, but that after the gases have been driven off by heat, the extra luminescence is lost, and can only be regained after prolonged cooling and rest. The other theory is that the increase of resistance accompanying rise of temperature takes a certain small interval of time to be established, so that when the temperature is rising at the rate of tens of thousands of degrees per second, the resistance lags appreciably. The resistance does not shut off the current as promptly as it should, and an extra rush of current and heat energy gets through the filament, bringing the temperature higher than normal, with a corresponding increase in brilliancy. According to the experiments which were described in the article, the overshooting of current took place without any increase in candle-power when the filament was warm, and if this was the case, the second of the two theories cannot be the correct one. The matter is of more than purely scientific interest. We believe that it is already recognised that practically all makes of metal filament lamp have a shorter life if they are frequently switched on and off than if they are continuously burning. This is probably due, at any rate in part, to this "overshooting," and any researches that help to explain the cause of this phenomenon and to bring us nearer to a remedy are welcome.

IT appears that at any rate the commercial element of the electrical engineering industry is not strongly represented in Dublin at the British Association meeting. In this there is no great departure from the general rule, but the gas engineers have put in a strong appearance, attracted by the fact that Mr. Dugald Clerk, who has made the study of gas engines particularly his own, is president of the Engineering Section. Mr. P. W. Robson's Paper on suction gas plant is conceived in a truly commercial spirit, and his case for suction gas as against electric power is exceedingly ably put. Electrical engineers have frequently presented an equally strong case against it, and it is to be regretted that their side was not represented in any way in Dublin. There is little need to prompt our readers with the proper answers to Mr. Robson—a few instances of suction plants being replaced by electric motors after a short trial will probably go as far as sheets of figures, and although this line of argument may not be so strictly logical, it will carry conviction as easily as Mr. Robson's bald extract from the report of Mr. MICHAEL LONGRIDGE, Chief Engineer to the British Engine, Boiler & Electrical Insurance Co. To quote simply the percentage of gas engine breakdowns as compared with the motor breakdowns without giving particulars of the numbers incurred, the conditions of the two policies, or the cost of the repairs should not carry conviction to many. Similarly the figures in Mr. Robson's table apparently take no account of works load factor, losses in shafting and belting, and other matters which are of considerable importance in considering the problem. Moreover, two of the three cases for which he gives figures are quite possibly instances, from their nature particularly adapted to independent plant. In the third case the charge of £12 10s. per annum for "attendance, &c.," on any gas plant, however small, is exceptionally low, and an increase of a few pounds in this would clearly give the benefit to the electric motor. We have, however, already been tempted to depart too far from our intention not to discuss these details, and will leave our readers to pick further holes in Mr. Robson's argument. At the same time, they will be grateful to him for a particularly clear and well-written Paper on suction gas plant, which will be read with no little benefit to those connected with a kindred industry.

ALTHOUGH there are now several large ocean-going liners and warships fitted with steam turbines in place of the highly-developed marine reciprocating engines, it is well recognised that two of the chief advantages which are gained under other conditions by the substitution of steam turbines for reciprocating engines, namely, low steam consumption, and low weight per horse-power developed, are not so apparent in marine work, owing to the necessity of using slow speed turbines. As was mentioned at the British Association meeting last week, for large powers, and to obtain a high propeller efficiency, it is essential that the propellers should be large in diameter, and should rotate at a comparatively slow speed. On the other hand, as is well known, the lowest steam consumption and weight per horse-power developed are obtained with very high-speed turbines. It has thus been necessary to make a compromise between these two extremes and thus sacrifice economy in both generation and propulsion. It was realised at an early date that one solution of the problem would be to run both turbines and propellers at their most economical speeds, and connect them electrically. Various methods of carrying this out have been proposed, and for descriptions of some of these we refer our readers to the paper read by Mr. H. A. MAVOR before the Institution of Engineers and Shipbuilders in Scotland, of which we gave an abstract in our issue of March 12th last, and also to the Paper by Mr. W. P. DURTNALL, which was given in an abbreviated form in our issue of July 23rd. In both of these Papers it was pointed out that continuous current motors of such large powers as would be required for marine propulsion were hardly practicable machines, and that therefore polyphase motors would have to be used. The same can be said as regards the generators, as it is well known that high-speed turbo-alternators are more satisfactory in every way than high-speed continuous-current turbo-generators. With ordinary polyphase motors, the difficulty of reversing which is one of the most important in direct driving with turbines, is at once eliminated; but the other difficulty, that of running efficiently at speeds lower than the normal, remains. When going in and out of harbour, running in foggy weather, and in the case of warships when manœuvring, it is essential, moreover, that the ship should be capable of running efficiently at one or more speeds considerably below the normal; and as the ordinary polyphase synchronous motor can only run efficiently at one speed, some method of varying the speed must be devised. The motors with double stator windings for producing two different numbers of effective poles are expensive, and only give two speeds. In a patent specification abstracted in our issue of August 20th, Mr. H. A. Mavor described his type of polyphase induction motor with rotating "stator" which has proved of considerable use in other directions than marine work; and again in our issue of August 27th another patent specification by Mr. Mavor for a system of marine propulsion with variable-frequency constant-speed turbo-generators was abstracted. In this system special generators, with means for revolving the armature winding concentrically round the rotor field winding, were proposed. A still further method for producing variable propeller speed with constant speed generators is described by Mr. Mavor and Mr. W. B. Hird in a patent specification published last Thursday and abstracted in our Patent Record on page 411 of this issue. This method consists in having three or four turbo-alternators generating at different frequencies and a corresponding number of motors on the same shaft, with different numbers of poles. By suitable grouping the motors can be rotated at the same speed, or two can be supplied at such a frequency that they run at a higher or at a lower speed than the normal. It is contended that the saving in weight of boilers, coal, and other items of the steam equipment owing to the lower steam consumption to be obtained with high speed turbines, and the elimination of the reversing turbine, will more than compensate for the extra weight of the electrical equipment and the inevitable losses in the generators and motors; but of course in the case of a radical departure such as this, each inventor is an ardent enthusiast, and, needless to say, much more work will be necessary before an entire revolution in marine propulsion is imminent. The problem is, however, a fascinating one, and does not lack elements of considerable promise.

THE AIRSHIP EXPLOSION AT THE FRANCO-BRITISH EXHIBITION

THE evidence and verdict at the adjourned Coroner's inquest on Monday into the deplorable airship accident at the Franco-British Exhibition on August 14th has elicited the fact that the gas was ignited by a spark from the switch at the base of an electric fan which was being used to pump air into the balloon to replace some of the hydrogen which had been lost through leakage. It will be remembered that the explosion and fire took place in a tent containing an airship, belonging to a Mr. Lovelace, by which three persons lost their lives, and a number of others were very seriously injured.

The following account of the facts of the case and the conditions obtaining on the day of the accident has been compiled from the evidence at the inquiry and interviews with one or two of those prominently identified with the case.

It appears that Mr. Lovelace rented a space from the Franco-British Exhibition authorities which he termed somewhat euphemistically an "aeronautical concourse." Upon this were built a number of tents, one containing an airship, capable of holding 10,000 cubic feet of gas. In another tent, some distance away, was the hydrogen gas generating plant, whilst upon the ground were also a number of captive balloons. The airship tent was 120 ft. long, 45 ft. wide, and 37 ft. high, and the gas bag of the airship was 75 ft. long by 16 ft. diameter. The tent was open at both ends, and, in addition, there were two openings on each side. The envelope of the airship was constructed of silk, covered with varnish, over which a coating of aluminium composition had been spread.

The tent was lighted with electricity by means of "Fairyland" strip, and 75 to 100 lamps were in use. The system is that used for the decorative scheme of lighting all the buildings of the exhibition. In this a form of metal-backed strip is made use of; the lamp-holders are of the central pin and screw terminal type, and there is a packing ring by which an absolutely water-tight joint is maintained. We described and illustrated the system in connection with our articles upon the Franco-British Exhibition (ELECTRICAL ENGINEERING, July 2nd, p. 27). The lighting strip in the present instance was suspended every nine inches from No. 12 gauge galvanized wire, and was taped at the points of suspension to prevent the wire from cutting it. Another feature in the electric lighting was the provision, at the request of Mr. Lovelace, of "safety" plugs, in addition to the ordinary fuses. These are ordinary plugs, so arranged between the wiring that any extension of the distance between the vertical poles of the tent pulls them out and cuts off the current. This device, which is used extensively in America for circuses, has the double virtue for such cases that in the event, for instance, of a tent being blown down, it prevents persons receiving shocks and also obviates fire. In a tent containing a bag of hydrogen gas, on the other hand, its employment is a questionable advantage, for on the tent blowing down, some gas would in all probability escape, and a spark due to the plugs pulling out might conceivably occur simultaneously and ignite the gas.

It may be stated, however, at the outset, that this device was not the cause of the present fire, for which, in fact, the lighting arrangements were in no way responsible. The installation had been inspected and passed on behalf of the electrical and mechanical engineer to the London County Council Fire Brigade.

Later there was introduced an electric fan, mainly for ventilating purposes, but, as has been mentioned, it was used for another and most unusual purpose subsequently. This fan was an alternating current fan of the pedestal type, commonly seen in offices, and was worked by plugging into a lamp socket; the usual switch was situated in the base of the fan, and, of course, sparking would occur at this switch when it was switched off.

These, then, were the conditions on the morning of August 14th. It seems to be accepted by aeronauts, according to Mr. Lovelace, that the envelopes of their airships are never absolutely gas-tight, and so it was that various rents and "pin holes" were being mended, although, generally speaking, the condition of the bag was regarded as satisfactory. Whilst these holes were being mended with stitches and patches stuck on with rubber solution, instructions were given to blow the bag tight by pumping in air. This was accomplished by holding the neck of the envelope over the wire frame of the electric fan, a man holding the two in position between his legs, whilst sitting on the floor. It is well known that hydrogen and air in the proportions of 6 to 1 form a highly explosive mixture, but Mr. Lovelace contended that, whereas only about 500 to 800 cub. ft. of air would be put into the envelope, the 9,000 to 9,500 cub. ft. of hydrogen which the bag contained would remain at the top, and in proof of his argument mentioned that he had actually worked with his head inside the lower portion of an airship envelope in which the air was at the bottom and the hydrogen at the top, and thus there was no diffusion of the gas into the air.

There was some conflict of evidence as to the exact length of time the fan was actually working, and the man who carried out this operation has subsequently died in hospital as a result of his injuries. Mr. Lovelace said that he himself found the motor not working, and tied up the neck of the envelope. His chief assistant asserted that he had taken the motor away from the man who was working, with instructions that sufficient air had been pumped in, a view which was not shared by the man in question, and who was subsequently heard to say that he would put a little more air in. The man also stated in hospital that the motor was working right up to the time of the accident. A theory held by several, therefore, is that after the motor was actually seen not working by Mr. Lovelace and his chief assistant, some ten minutes before the accident, the man in charge of it did commence pumping more air in, and that this accounted for several other witnesses swearing that the motor was heard humming within a minute or so of the explosion. Accepting this possibility, the Coroner suggested that what had happened was that, as the air continued to be pumped in, the pressure of the incoming air began to be neutralised by the pressure of the gas inside, and that a point of equilibrium was reached which resulted in the mixture of gas and air finding its way back and entering the partially enclosed motor, a small spark from which caused a circumscribed explosion, followed by the fire. This theory was, more or less guardedly, supported by Mr. Eustace Ridley, the electrical and mechanical engineer to the London County Council Fire Brigade, and Mr. Frank Converse, the electrical engineer to the Franco-British Exhibition. Of course, the alternating current induction motor used for the purpose would have had no commutator, and what probably occurred is that the man, finding the balloon full and the gas coming out, switched off the motor, and that the spark at the switch ignited the gas. It was stated that the man who had charge of the motor and who had been seen sitting on the ground, was badly burned about the legs, and had said in the infirmary, before he died, that burning gas seemed to come down the neck of the envelope, which he was holding.

Digitized by Google

Whilst putting forward no direct theory as to the cause of the fire, Mr. Lovelace's legal representative made several suggestions as to a possible cause. He tried hard to demonstrate that a celluloid or xylonite comb, which Miss Hill—Mr. Lovelace's secretary, who was burned to death—had in her hair, had been set on fire by sun rays coming through holes in the tent where the poles entered, and also that static electricity had been generated at some point in the envelope where there was a pin-hole leakage; on the latter point, Mr. Ridley and Mr. Converse quickly mentioned that the metallic nature of the covering of the envelope would dissipate it at once. An attempt was also made by the lawyer representing the widow of the deceased, to fasten upon the electric lighting installation as the cause of the accident, but in this case an inspection had shown that, although the wires were burned by the fire, none of the fuses had blown, and the collapse of the tent, which will have withdrawn the "safety" plugs naturally occurred after and not before the explosion. Any question of smoking in the tent or smouldering cotton waste was quickly negatived by every witness. Nothing, moreover, can be traced to the gas plant, as this was out of commission at the time of the accident.

Two other facts with regard to the motor came out at the inquiry. One was that none of the witnesses could remember seeing it spark at any time, and the other that Mr. Lovelace's chief assistant had never seen an electric motor used for pumping air into an airship before, and that it was a responsibility which he himself would not have undertaken. Some suggestion of blame attaching to the London County Council was made by a juror of having passed an installation of such a dangerous character as this, and in reply it was stated that the L.C.C. merely inspected the arrangements from the point of view of the safety of the public, and at a time when the airship was fully inflated and floating close to the roof of the tent. No pumping with the electric fan was then taking place, nor did it ever take place whilst the public were viewing the airship. What Mr. Lovelace chose to do at a time when the public were excluded from the show ground, said the L.C.C. representative, did not come within the purview of the County Council.

In the end, the jury's verdict was that the deceased met their deaths from burns by the explosion of the airship, caused by using an electric fan for forcing air into the ship, and the use of which, in the circumstances, they considered dangerous. With the characteristic indulgence of a coroner's jury they attached no blame to anyone.

HASLINGDEN CORPORATION TRAMWAYS

ON Thursday last Major Druett, for the Board of Trade, made an official inspection of the first portion of the reconstructed Haslingden tramway system, accompanied by the Mayor and Corporation, the Town Clerk, the Surveyor, and the Consulting Engineers; the line was opened for traffic on Saturday. As mentioned in our issue of last week, the Accrington Corporation has agreed to supply cars and also current for this section of the line for a period of nine months, for which the Haslingden Corporation pays 7d. per car mile. The section of the line already completed is that connecting Haslingden with Accrington, and is about half the length of the whole line, which connects Accrington, Haslingden, and Rawtenstall, and is nearly three miles long.

It will be remembered that the original scheme for the supply of electric light and power to the three towns, Bacup, Haslingden, and Rawtenstall, from the Lancashire Power Co.'s mains fell through, and that Rawtenstall then erected its own generating station for its own lighting supply and for that of Bacup.

On account of the distance between Rawtenstall and Haslingden, and the small demand for electric light in the latter town, the Corporation was recommended by its consulting engineers, Messrs. Handcock & Dykes, neither to buy electrical energy in bulk from Rawtenstall, nor to erect their own station for the present. A large refuse destructor is now under construction in Haslingden, however, and as a boiler is a necessary item of such a plant, it has been decided to instal a 60-kw. steam generating set in the destructor station, and supply power for the tramways from that.

Another 60-kw. gas- or oil-engine set will be used as a standby, and the usual battery and booster equipment will be installed. An application has been made to the B.O.T. for sanction to raise a loan of £7,200 for this purpose.

The destructor is very favourably situated in the centre of the tramway system, and there are no return feeders. The single main feeder pillar is only a few yards from the station, and is connected with the latter by a 0·2 sq. in. Callender bitumen cable. The rails are connected to the station also at this point only. There are seven Callender section pillars, and telephonic communication between any pillar and either the generating station or the car depôt is provided.

The whole of the line is single-track with turn-outs at frequent intervals. The overhead equipment has been carried out by Messrs. Dick, Kerr & Co., Ltd., to the specifications of Messrs. Handcock & Dykes, and is on the Pringle tangential system (*see* ELECTRICAL ENGINEERING, Vol. III., page 46).

There are only one or two span wires on the system, side brackets with 15-ft. arms being mostly used. The trolley wire is No. 0,000 round wire, and is soldered to the ears. The two trolley wires are spaced two feet apart. Section insulators of the Pringle type are used. Except for a short length between the main feeder pillar and the station, the pilot wires are carried overhead.

The construction of the track was carried out by Mr. J. Singleton Green, the Borough Surveyor, to Messrs. Handcock & Dykes' specification. This consists of 95-lb. rails laid on a cement concrete bed, with granite setts between the rails, and extending to 18 in. on either side of the rails. Anchor rails were fitted every 14 feet, and also on either side of every joint at a distance of 2 ft. 6 in. These were constructed out of the old rails used for the original steam trams. The joints are all welded by the Thermit process. The rails are cross connected every 60 yards. The tie bars are spaced a little over six feet apart.

The cars for the system will be double-deck cars, but they will not be ordered until it is quite certain how many will be required. If the Rawtenstall and Accrington Corporation cars run through in both directions there will be only the local service for the Haslingden cars to do. Until arrangements have been made with regard to this matter, the number of cars required cannot be estimated.

An innovation in the construction of the tramway poles is the provision of ventilating holes in both the pole itself and the base. Four ¾-in. holes are provided at the top of the pole, and four at the bottom, while the base has six holes at top and bottom. By this means a thorough ventilation of the interior of the pole is ensured, and "sweating" is avoided. The concrete at the base of the pole is also carried up a few inches above the ground level, inside the base, to keep the pole from contact with any water that may accumulate in the base below the ventilating holes.

A NEW VARIABLE SPEED SINGLE-PHASE MOTOR WITH HIGH STARTING TORQUE

IN connection with the electric driving of lifts, cranes, paper-making machinery, and various other types of machinery, it is essential that the motor employed should be capable of developing a large starting torque, while for other machinery a wide range of speeds at high efficiencies is important. The ordinary continuous-current motors have served well in these respects, but there is a considerable demand for a single-phase motor having these characteristics, and many attempts have been made to produce one. A new modification of the repulsion type of single-phase commutator motor has lately been developed by Mr. H. C. E. Jacoby, in order to fulfil these requirements. In this motor commutation difficulties are reduced to a minimum by eliminating in a very simple manner the chief source of commutator troubles inherent to these types of motors. It is common knowledge that when an ordinary continuous-current winding connected to a commutator is employed in alternating current work, the coil undergoing commutation is in such a position that it encloses the whole magnetic flux, as is shown in Fig. 1. This flux being alternating induces a considerable E.M.F. in the short-circuited coil. This E.M.F. is out of phase with the main rotor current, and causes large surging currents to flow in the coil. Attempts have been made to reduce this short-circuit current by inserting resistances between the windings and commutator bars, but there are many disadvantages to this method. Now in order to obtain sparkless commutation it is necessary that an E.M.F. should be provided in the short-circuited coil of just sufficient value to reverse the current. This, as is well known, is generally done in continuous-current motors by the use of carbon brushes which, by introducing a gradually increasing contact resistance at the leaving bar, thereby produces a drop of potential across the contact; and this, by a suitable choice of carbons and constants, produces excellent results. It will readily be seen that in the case of an alternating current motor with an alternating E.M.F. of consider-

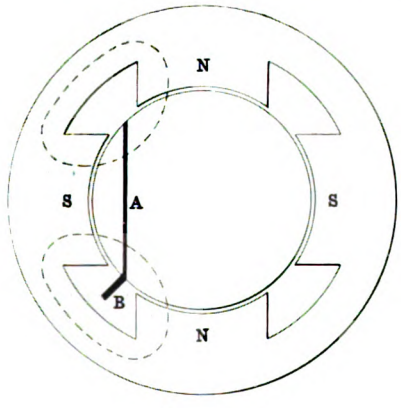

FIG. 1.

able value induced in the short-circuited coil, which is out of phase with the current, bad and deleterious sparking must result unless some very special method is used to counteract these defects. In the motor we are describing the rotor winding is so arranged that the coil short-circuited by the brush encloses little or no magnetic flux, *i.e.*, is parallel to the transformer flux, with the consequence that commutation is brought under similar conditions as in continuous-current motors, and can be provided for with, it is claimed, equally good results. This is accomplished without any complicated connections. The rotor coils are wound across a particular fractional pitch—much less than anything previously employed—and the brushes are placed in a position so that the short-circuited coil lies parallel to the transformer flux as shown in Fig. 2.

With this arrangement there are zones on the rotor in which the current flows in opposing directions in

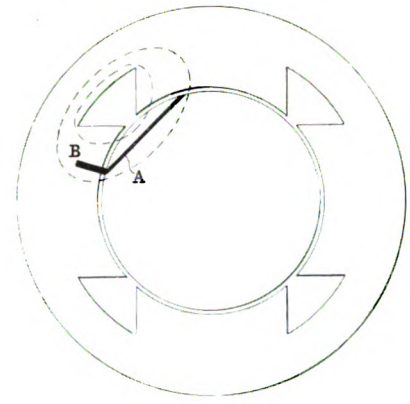

FIG. 2.

adjacent wires. At first sight it would appear that this method of winding would result in considerable loss of torque, and, if it were employed on a continuous-current motor, the resultant torque with equal currents would be less than half what it would be with an ordinary winding. In this case, however, it is claimed that this mode of winding actually increases the resulting torque. In the first case, by eliminating the heavy currents in the short-circuited coils, a troublesome source of back torque is also eliminated. Also the effect of the currents in the rotor conductors causes a displacement in phase of the magnetic flux in a portion only of the solar face, and to obtain the best results it is necessary that the coils doing motor work should be designed with shortened step to suit this. This arrangement of the winding is such that the total ampere turns reacting on the motor flux and producing a torque are not lessened.

It is claimed that, with this winding, equally good commutation is obtained with any brush position between that of maximum and minimum torque; and that this feature makes it possible to govern the speed of the motor by shifting the brush position only. When a shunt characteristic is desired a simple centrifugal governor is employed, arranged to vary the position of the brushes to suit the load. The fact that the friction of the brushes causes the brush rocker to tend to revolve in the direction of rotation greatly facilitates this control. As the brush rocker and brushes would revolve were they not prevented from doing so by the governor, it is only necessary that this latter should exert a force equal to the friction of the brushes, and the slightest deviation from this amount will cause the brushes to advance or recede. The speed can easily be governed by this means within 5 per cent. of the normal. When a variable speed motor is required for direct gearing to a machine—such as a printing press—excellent results are said to be obtained by simply attaching a cord to the brush rocker, by means of which the speed can be varied from a very low speed to full speed.

If a variable speed motor with a shunt characteristic is desired, the motor is assembled with a governor

and the speed is varied by adjusting the tension of the governor spring. This spring is in an accessible position, so that a distance control can be arranged by levers or by means of an auxiliary motor.

We are informed that tests taken on a 5 h.p. motor at 900 r.p.m. on a single-phase circuit of 200 volts 50 periods, showed the machine to have a full load efficiency of 85 per cent., and a half load efficiency of 77 per cent., a power factor of 0·85, and further that a starting torque of one pound per 100 volt-amperes at 1 ft. radius was developed between normal starting torque and 2½ times full load torque. It is also stated that the speed range is practically unlimited, and that a motor may be switched straight into circuit without a controller or starter of any kind, and 1½ times full load torque will be developed with approximately full load current, and twice full load torque with 1¼ to 1½ times full load current, according to the speed and size of the motor and general conditions.

As previously mentioned, the machine can be assembled as an ordinary variable speed power motor

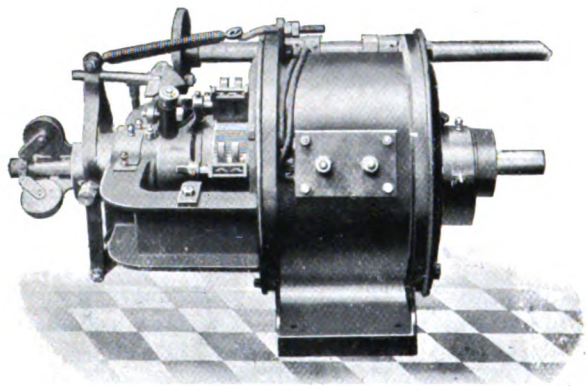

FIG. 3.—JACOBY MOTOR WITH SPEED-REGULATING GEAR.

with the same characteristics as a series wound continuous-current machine. It then has its speed regulated and direction of rotation controlled by rocking the brush gear, or alternatively its speed varied only by an ordinary rheostat put in series with its stator winding. Any suitable mechanical coupling gear may be attached to the brush rocker so that the necessary convenient control be obtained.

The illustration above shows the motor with brush rocking gear coupled to an automatic centrifugal governor, switch, and controlling shaft, the form of assembly supplied where it is desired to control the speed of the motor automatically, as for electric lifts and similar drives. This condition is obtained by the centrifugal governor automatically throwing the brush gear into a position which limits the speed of the motor, the maximum speed being determined within a wide range by adjustment of the spring tension anchored to the housing lug on the top of the yoke. This motor is primarily controlled by turning the controlling shaft through an arc of, say, 150 degrees in either direction to and from a neutral point, the direction of rotation of the motor being the opposite to that in which the gear is rocked from the neutral point.

This motor has been placed on the market by Messrs. Bergtheil & Young, Ltd., of 12 Camomile Street, London, E.C., and is being manufactured at their London works. The motor is known as the "Bandy" patent variable speed single-phase motor.

Electric Headlights for Locomotives.—The Georgia legislature, according to the *Railway Gazette*, has just passed a law requiring railways to use electric headlights on the locomotives of all through trains.—The legislature also passed a Bill providing for the punishment of telegraph companies which may fail to deliver a telegram promptly.

PARIS TO NEW YORK WIRELESS TELEGRAPHY AND TELEPHONY

AS was recently announced in our columns, a contract has been made between the Metropolitan Life Insurance Co. and the De Forest Radio-Telephone Co., under which the latter company is to establish a powerful wireless telephone station in connection with the 700 ft. tower of the Insurance Co.'s building at No. 1 Madison Street, New York.

Negotiations were begun early last spring, when Dr. Lee De Forest was conducting some wireless telephone experiments for the French Government at the Eiffel Tower in Paris. During the course of these experiments, we are informed that wireless messages from the station at Glace Bay, Nova Scotia, were received in Paris, while the wireless telephone using the high antenna on the tower was heard at distances of several hundred miles, although the apparatus then employed was only of 2 h.p. capacity. Dr. Forest then made formal application through the United States Minister, Mr. White, to the French Ministry of War, which controls the wireless station on the Eiffel Tower, in order to obtain permission to carry on experiments between Paris and New York. The officials to whom the matter was referred entertained the proposal willingly, and steps were taken immediately to increase the power of the Eiffel Tower station up to 30 kw.

As soon as the new tower on the Metropolitan Life Insurance Co.'s building is completed, an antenna consisting of six or eight small copper wires will be fastened on its topmost balcony on the 52nd floor just under the lantern. These wires will be insulated from the metal frame of the tower and will run down diagonally, clear to one of the ends of the main building, where the apparatus will be placed in a pent-house. In this way the wires will be over 700 ft. long, and sufficiently clear of the steel frame of the tower. The station will be 150 ft. above the roadway beneath. At the New York end the apparatus will be of 10 kw. capacity, and the De Forest Co. estimate that it will be capable of covering a distance of 1,000 miles with the present type of apparatus.

Experiments will probably then be made between New York, Philadelphia, Boston, Chicago, and Cuba, with the idea of gradually improving the apparatus until communication with Paris is possible. The apparatus has been under construction for some time, and it is hoped that the new station will be in operation by November 1st.

It is also announced that one of the first duties which the new station will take up, will be to send hourly bulletins of news and weather reports to the ships at present equipped with wireless telegraph and telephone apparatus on the De Forest system. From the information issued by the De Forest Co., it appears that it is also contemplated to transmit gramophone music by this means to the ships at sea.

We are informed that the wave-length used will be about 1½ miles, but a change-over from this length to shorter lengths will be possible. The company is also confident that there will be no interference with other systems.

In a letter enclosing these particulars, Dr. De Forest informs us that he expects that it may take two years to establish the wireless telegraph service between New York and Paris, and from five to ten years before the wireless telephone experiments are actually completely successful. He assures us that he does not contemplate a public "opening day," but that the service will be established gradually, as experimental trials merge more and more into commercial ones.

Electric Power Supply in South Africa.—According to a Transvaal correspondent of the *British South African Export Gazette*, the extensions to the power station at Brakpan have just been completed. This station is the property of the Victoria Falls Power Co., Ltd. To the old equipment of four three-phase generators of 750-kw. capacity each, generating at 2,500 volts, and driven by four reciprocating steam engines, with 10 boilers of 500-h.p., there have been added two three-phase turbo-generators, and eight Babcock and Wilcox water-tube boilers, thus more than trebling the capacity of the station. The new generators are each of 3,000-kw. capacity, generating at 10,000 volts. The pressure is transformed up to 40,000. The turbines are of the A.E.G.-Curtis direct-coupled type, and the boilers have a capacity of 1,500-h.p. each. The company's Germiston station, which is still in course of construction, will possess even double the capacity of the new plant at Brakpan when completed early next year. Meanwhile, the Johannesburg Corporation have decided not to continue the arrangement under which they have been taking current from the company, but have, instead, called for tenders at very short notice for the supply of new generating plant, consisting of a 1,000-kw. steam dynamo, boiler, condensing plant, and pipes, estimated to cost £21,000, and to be erected by December 15th, 1908.

THE SEVENTY-EIGHTH MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

(By our Special Correspondents)

THE Dublin meeting of the British Association opened on Wednesday, September 2nd, with the presidential address of Mr. Francis Darwin, M.A., Ph.D., LL.D., F.R.S., delivered in the Great Hall of the Royal University of Ireland. There was an exceptionally large attendance, the number of members being close upon 3,000, and the spacious hall was filled to its utmost capacity. An unusual element of stateliness was lent to the meeting by the presence of the Earl of Aberdeen, the Irish Viceroy, whose entrance was heralded by the strains of the National Anthem.

The presidential address dealt mainly with movement in plants. The speaker, a third son of the famous Charles Darwin, defended his father's position connected with the inheritance of acquired characters, and made an eloquent plea for the recognition of an elementary memory, a rudimentary "soul," in plants, quoting numerous illustrations of their apparent intelligence.

In the afternoon a meeting of the General Committee of the Association had taken place, at which it was reported that Prof. J. J. Thomson had been unanimously nominated by the Committee as President of the Association during next year's meeting, which will be held at Winnepeg.

THURSDAY, SEPTEMBER 3RD.

Mr. Dugald Clerk's Presidential Address to the Engineering Section.

Mr. DUGALD CLERK, F.R.S., in his Presidential Address to the Engineering Section (Section G), dealt with the history of thermodynamics. At the middle of the last century, he said, the science of thermodynamics did not exist, although the steam engine had attained to a high degree of perfection. The steam engine had been successfully applied to all the great duties of the mine, the waterworks, the factory, the railway, and the steamship. The engines were mechanically excellent; the fuel economy was good, and they were built in units of thousands of horse-power. Steam power, in fact, was revolutionising the whole of the social and industrial conditions of the globe. Notwithstanding this great material and engineering success, the world was in complete darkness as to the connection between steam motive-power and heat. It was seen that motive power of almost any magnitude could be obtained by the agency of heat; but how it was obtained and how much power was connected with a given quantity of heat was quite unknown. The fuel consumptions of existing engines were known, and certain modes of improving economy were evident, and engineers were busily engaged in testing these modes by the slow but sure methods of invention, design, construction, and operation in practical work; but in this they had but little aid from pure science.

Men of the first rank in intellect—Newton, Cavendish, Rumford, Young and Davy—had long before expressed the opinion that heat was not material in its nature, but was a mode of motion; but their opinions, although to some extent supported by experiment, had made little impression upon the scientific world, and in 1850 the most distinguished physicists still adhered to the "caloric" or material theory of heat.

Carnot had, however, in 1824, published in Paris a pamphlet entitled "Reflections upon the Motive Power of Heat." He saw that heat and motive power were connected in some manner, and he endeavoured to settle in a quantitative way the limits of that connection by the invention of an ideal series of operations by means of which the greatest conceivable amount of mechanical power may be obtained from a given quantity of heat under given circumstances. For the purpose of his demonstration he assumed only two things: (1) That if heat be added to any body under standard conditions of temperature, pressure, and volume, and the body be carried through any series of mechanical processes, returning ultimately to the standard condition of temperature, pressure, and volume, then the quantity of heat added to the body would be the same as that which had been discharged from it; (2) No process can exist whereby a given mechanical energy can increase its own quantity. On these indisputable assumptions he based his ideal cycle, which consists of four simple and easily imagined operations, occurring within a cylinder behind a piston, so arranged that during the cycle work can be done by the working fluid upon the piston or work be done by the piston on the working fluid.

First Operation.—The given volume of the working fluid is to be imagined as confined at its highest temperature and pressure behind the piston, and heat is to be added to keep the temperature constant, while the fluid expands, moving the piston and doing work upon it.

Second Operation.—The supply of heat is cut off, and the working fluid expands also doing work on the piston, while its temperature falls to the lowest point, and its volume increases to its maximum.

Third Operation.—The piston returns, compressing the working fluid, but allowing the heat of compression to escape, so that the temperature remains during the operation at its lowest point.

Fourth Operation.—The piston compresses the working fluid, without allowing any loss of heat, to such an extent that the temperature rises again to its highest point, and the working fluid exists at the end of this operation at the same volume, pressure, and temperature as at the beginning.

This assumed series of operations would give a certain available work area, the indicated power of the engine, inasmuch as the work done by the working fluid would be greater than that done upon it. If however it be assumed that in all the operations the direction of motion of the piston be reversed, then compression without loss of heat would take place in the second operation; further compression, but with sufficient heat loss to keep temperature constant, would occur on the first operation; the fourth operation would follow with expansion, and the third operation would conclude also with expansion. The engine would be reversed by beginning with the second operation, moving the piston backwards in the order second, first, fourth, third. Carnot showed that this reverse operation would be performed by exactly the same amount of work as was given out by the direct operation, and that an amount of heat would be returned at the higher temperature equal to that which was added in the first case.

An engine which fulfils these conditions, Carnot stated, will give the greatest amount of work which can be obtained from a given quantity of heat falling through a given temperature range. And it is evident that this must be so, because, if the existence of any engine is assumed, under the same conditions giving a greater amount of work from the same heat, then that engine could drive a Carnot engine in the reverse direction in such proportion as to return to the higher temperature a greater amount of heat than it abstracted, and so mechanical energy could be obtained without any heat fall whatever. This marvellous demonstration is obviously independent of the nature of the working fluid; it applies equally to all working substances, whether solid, liquid, or gaseous, whether the physical state changes or not. It at once gives a standard of the limit of mechanical power which could possibly be obtained from a given amount of heat and a given temperature fall.

To reduce this limit to numerical values it was necessary, however, to experiment on any one working fluid within the desired temperature range in order to determine the work area in its relation to heat quantity and temperature fall. Carnot's writings show that he intended to make such observations; and, had he succeeded, thermodynamics would have become a science at an early date. Carnot's death, however, in 1832, at the early age of thirty-six years, prevented this development.

Carnot's work remained practically without notice for thirteen years after his death, when, fortunately, it attracted the attention of William Thomson during his attendance at the Laboratory of Regnault in the year 1845. Thomson, who was then twenty-one years of age, and had already attained a considerable scientific reputation, took up the study of Carnot's work with enthusiasm. He became Professor of Natural Philosophy in the University of Glasgow in 1846, and in 1848 he read a Paper before the Cambridge Philosophical Society "On an

Digitized by Google

Absolute Thermometric Scale founded on Carnot's Theory of the Motive Power of Heat and calculated from Regnault's Observations." Like Carnot, Thomson accepted the "material" or "caloric" theory of the nature of heat, although, like Carnot also, he had doubts as to its truth. He carried Carnot's reasoning much further, and deduced from the Carnot cycle a thermometric scale which was absolute in the sense that it defined the idea of temperature independently of the properties of any particular body.

Thomson followed up his absolute thermometric scale work with an investigation entitled "Carnot's Theory of the Motive Power of Heat," described in a Paper read in 1849 before the Royal Society of Edinburgh, in which he calculated from Regnault's experiments on steam the power developed by a Carnot reversible engine when using one centigrade heat unit; that is, the heat necessary to heat one pound of water through 1° C. for temperatures from 1° to 231° C., the temperature falling in the engine in each case to 0° C.

The Paper is of great interest because it shows clearly how fully the distinguished author realised the necessity for re-examining the standard ideas of the nature of heat. Two paragraphs make this very clear :—

"7. Since the time when Carnot thus expressed himself the necessity of a most careful examination of the entire experimental basis of the theory of heat has become more and more urgent. Especially all those assumptions depending on the idea that heat is a substance, invariable in quantity, not convertible into any other element, and incapable of being generated by any physical agency; in fact, the acknowledged principles of latent heat would require to be tested by a most searching investigation before they ought to be admitted, as they usually have been, by almost everyone who has been engaged on the subject, whether in combining the results of experimental research or in general theoretical investigations.

"8. The extremely important discoveries recently made by Mr. Joule, of Manchester, that heat is evolved in every part of a closed electric conductor moving in the neighbourhood of a magnet, and that heat is generated by the friction of fluids in motion, seem to overturn the opinion commonly held that heat cannot be generated, but only produced from a source where it has previously existed either in a sensible or in a latent condition. In the present state of science, however, no operation is known by which heat can be absorbed into a body without either elevating its temperature or becoming latent, and producing some alteration in its physical condition; and the fundamental axiom adopted by Carnot may be considered as still the most probable basis for an investigation of the motive power of heat, although this, and with it every other branch of the theory of heat, may ultimately require to be reconstructed upon another foundation when our experimental data are more complete. On this understanding, and to avoid a repetition of doubts, I shall refer to Carnot's fundamental principle, in all that follows, as if its truth were thoroughly established."

In these two paragraphs Thomson summed up the whole situation in 1849, and promised further investigation and further attempts to deduce the nature of the connection between heat and work. Thomson's promises of further investigation were fulfilled in 1850, in which year he definitely accepted the dynamical theory of heat and finally abandoned the material. His conclusions are given in a Memoir of the first importance which was read before the Royal Society of Edinburgh in 1851. It was entitled "On the Dynamical Theory of Heat."

Before dealing with it, however, Mr. Dugald Clerk dealt with the work of Joule and others on another side of thermodynamics. Long before 1850 the equivalence of mechanical work and heat quantity had been accepted by many scientific men, and Rumford had, indeed, made measurements of a rough kind. It remained, however, for Joule experimentally to determine the mechanical equivalent in the most accurate manner and place what is now known as the first law of thermodynamics upon the sure basis of absolute experimental determination. His first Paper was read before the Cork Meeting of the British Association in 1843, and at the Oxford Meeting in 1847 he read another—"On the Mechanical Equivalent of Heat"—describing the results of experiments with paddles rotating in liquids driven by falling weights. By these years of work he had absolutely demonstrated the equivalence of heat quantity and mechanical work, so that no loophole of escape seemed possible; it appeared as if the material theory was rendered intellectually impossible to the trained intellect. This was not the fact, however, as is evident from both Joule's and Thomson's accounts of that British Association Meeting.

Joule's earlier Paper had been coolly received. Indeed, it is evident that the idea of a mechanical equivalent of heat was still distasteful to the physicists of the day, and its discussion was looked upon with dislike. Joule, at the 1847 Meeting, addressed a small audience, and the account of his experiments was received without enthusiasm. This adverse atmosphere, so discouraging to the investigator, was quickly removed, however, when a young man rose to make his remarks, and, by his enthusiastic comment and clear reasoning, at once succeeded in attracting the interest of those present. This young man was William Thomson, Professor of Natural Philosophy in the University of Glasgow. Speaking of this, his first meeting with Joule, at Manchester, forty-six years later, Lord Kelvin said :—

"I can never forget the British Association at Oxford in the year 1847, when in one of the Sections I heard a Paper read by a very unassuming young man, who betrayed no consciousness in his manner that he had a great idea to unfold. I was tremendously struck with the Paper. I had first thought it could not be true because it was different from Carnot's theory, and immediately after the reading of the Paper I had a few words of conversation with the author, James Joule, which was the beginning of our forty years' acquaintance and friendship. . . . I gained ideas which had never entered my mind before, and I thought I, too, suggested something worthy of Joule's consideration when I told him of Carnot's theory."

This Meeting, Mr. Clerk continued, was indeed fateful for the future of the science of thermodynamics, as it resulted in co-operation between two men of giant intellect, who between them performed most of the experimental work which was necessary to make thermodynamics an exact science. Their work alone sufficed to place the first and second laws of thermodynamics on the firm footing of accurate experiment and logical deduction.

Although Thomson was much struck by Joule's experiments, he did not accept the dynamical theory of heat at once. As he stated himself : "I had first thought that it could not be true because it was different from Carnot's theory." Joule's discoveries at this date may be thus expressed :—Heat and mechanical energy are mutually convertible, and heat requires for its production, and produces by its disappearance, mechanical energy in the proportion of 1,390 foot-pounds for each centigrade heat unit, a heat unit being the amount of heat necessary to heat one pound of water through 1° C. Knowing, as Thomson did, that mechanical energy could be produced by the agency of heat, but that its amount varied with the temperature and temperature fall, Joule's discoveries seemed antagonistic to Carnot's demonstration; and, convinced as he was that Carnot's law was true, he naturally felt at first that there must be some other way of looking at Joule's results than that adopted by Joule himself. Joule had proved the generation of heat by means of mechanical work; Thomson required the proof of the converse case—the disappearance of heat when mechanical work was done by the working fluid.

This proof was forthcoming in the results of experiments on the compression and expansion of air. The Carnot and Joule principles were reconciled in Thomson's Paper of 1851, and the important deduction made of an absolute zero of temperature of −273° on the Centigrade scale. The introduction of the idea of the mechanical equivalent of heat led at once to an absolute zero of temperature, and allowed of the determination of this physical lower limit by the use of the Carnot cycle for investigating the efficiency of a perfect engine using any working fluid. Air was the working fluid actually investigated, and the determination of its properties at ordinary temperatures was a vitally important result of the co-operation of Thomson and Joule. Their experiments lasted for many years, and their rigorous investigation disclosed the fact that internal work was done in expanding a gas; in fact, that in a gas expanding isothermally doing work, part of the heat only disappeared in external work and part was absorbed in separating the molecules.

The Joule and Carnot laws are now known as the first and second laws of thermodynamics.

The second law, in modern form may be stated thus :—

Although heat and work are mutually convertible and in definite and invariable proportions, yet no conceivable heat engine is able to convert all the heat given to it into work. Apart altogether from practical limitations, a certain portion of the heat must be passed from the hot body to the cold body in order that the remainder may assume the form of mechanical energy.

The proportion of the total heat convertible into mechanical energy depends on the absolute temperatures of the hot and cold bodies; it is unity *minus* the lower absolute temperature upon the upper absolute temperature.

During Thomson's struggle to reconcile the two apparently opposing laws, Clausius, who had seen the same difficulty, arrived independently at its solution and published a Paper, "On the Motive Power of Heat and the Laws of Heat which may be deduced therefrom," at the Berlin Academy in

Digitized by Google

February, 1850. In this Paper, Clausius discussed Thomson's difficulties, and also arrived at the conclusion that the Carnot cycle may be reconciled to Joule's law by the omission of the supposition that during the third process the same amount of heat is discharged from the cool body as was taken in from the hot one. In his 1851 Paper, Thomson gave Clausius full credit for priority, but stated that he had been working on the same problem and had arrived at the same solution in the year 1850, before he had seen Clausius' work.

Rankine, as early as 1849, arrived at the general equation of thermodynamics which expresses the relation between heat and mechanical energy, and indicated the result of his investigations to the Royal Society of Edinburgh in February, 1850. Rankine thus arrived independently at the same result as Clausius about the same time. Both Rankine and Clausius, however, adopted certain theories as to the molecular structures and motions of gases, and their demonstrations to some extent depended upon their theories. To Thomson and Joule we are deeply indebted for the rigid proof of the two laws and for the rigid deduction of the modern scale of temperature and the determination of absolute zero in its modern form.

The brilliant work of Meyer, published so early as 1842, is held by some to have anticipated to a large extent both the work of Thomson and of Joule. Undoubtedly Meyer formulated true ideas and carried his generalisations through a wide range. Helmholtz also very early arrived at similar conclusions to those of Joule and Thomson. There is some little danger to the present generation, said Mr. Clerk, of forgetting what they owe to Thomson and Joule. To appreciate the step made by them it is necessary to consider the position of motive power produced by heat at about the middle of the last century. At that time many attempts had been made to displace the steam engine as a heat engine by air engines in various forms—both engines heated externally and those heated internally, now known as internal-combustion engines. Papers read at the Institution of Civil Engineers in 1845 and 1853, and the discussion of those Papers by eminent men of the day, supply an accurate measure of the knowledge possessed by the engineer of the principles of action of his heat engines. Many distinguished names occur in these Papers and Discussions, including James Stirling, Robert Stephenson, Sir George Cayley, Charles Manby, James Leslie, C. W. Siemens, Hawksley, Pole, W. G. Armstrong (afterwards Lord Armstrong), Edward Woods, E. A. Cooper, D. K. Clark, Benjamin Cheverton, Goldsworthy Gurney, George P. Bidder, Prof. Faraday, Isambard K. Brunel, Captain Fitzroy, and F. Braithwaite. At the date of the later of these discussions Brunel had already designed the *Great Eastern*, in 1852, with its engines of 11,000 h.p. Armstrong was a Fellow of the Royal Society, and had started the Elswick Works and invented the Armstrong gun. Robert Stephenson was at the height of his fame. He was then a Member of Parliament, President of the Institution of Civil Engineers, and a Fellow of the Royal Society. Siemens was a young man, but was busy on the regeneration furnace; he had considered regeneration as applied to steam engines, although his work on the air engine was still to come.

Of all the distinguished engineers who spoke, Siemens alone had thoroughly apprehended the value of Joule's results and understood the full bearing of the mechanical equivalent of heat. He had not, however, understood Carnot's reasoning on the Carnot cycle, or Thomson's deductions from Carnot. He was under the impression that heat added in any way to a working fluid, raising the temperature, could be entirely converted into work by a sufficient expansion. He had not appreciated that, even if expansion be carried far enough to reduce the temperature to the original temperature before heat addition, yet complete conversion of the entire mechanical equivalent was impossible. When so able a man as Siemens had at this stage only reached partial enlightenment, it was evident that much hard work and clear thinking required to be done before a well-founded theory of heat motive-power could be obtained.

The data for such a theory was accumulating. Regnault produced his admirable investigations, and succeeded in solving many problems; but he did not settle the questions to the extent he had hoped. Even at the present time doubt arises as to the very values he gave for the specific heat of air and steam. The problem proved much more difficult than he had anticipated, and for modern engine purposes it cannot be considered as wholly solved now—fifty-five years later.

In concluding his address, Mr. Dugald Clerk said :—The broad laws of thermodynamics have placed the theory of the heat engine in a position of certainty, which was much needed. It would be a mistake to assume, however, that even the determination of the mechanical equivalent of heat and the second law of thermodynamics expressed in terms of an absolute thermometric scale had solved all the difficulties of the engineer desiring to determine the efficiency of his heat engines. Thomson, Joule, Rankine, and their great Continental colleagues, it is true, settled once and for all the broad laws of thermodynamics, but the Carnot cycle is a cycle which is, as has been repeatedly shown, an impossible one in practice. Accordingly actual engines have to operate upon imperfect cycles. The theory of these imperfect cycles has been worked out mostly during the last twenty-five years, although Rankine made a beginning in dealing with the theory of the Joule air engine. For the first time he showed the existence of what may be termed a cycle of constant efficiency in the case of the Joule air engine. Assuming constant specific heat for the working fluid, he calculates the efficiency of what we now call a constant-pressure air engine between certain limits of temperature, and he gives the efficiency of the fluid where U = energy exerted and H_1 = heat received, and r = ratio of compression and expansion :—

$$\frac{U}{H_1} = 1 - \frac{1}{r^{0.408}};$$

that is, he indicates in this formula that the thermal efficiency is independent of the maximum temperature as long as that maximum temperature exceeds the temperature of adiabatic compression. He makes no statement, however, that this engine is within a certain range independent of the maximum temperature; that is, that increasing maximum temperature does not increase efficiency. Subsequent work has shown that, on a simple assumption, such as constant specific heat, many engine cycles exist of a practicable nature having high theoretical efficiencies where the theoretical efficiency depends on one thing only—the ratio of compression. Some misunderstanding has arisen with regard to these imperfect cycles, and it has even been thought that such imperfect cycles would be contrary to the second law of thermodynamics. Lord Kelvin himself was of this opinion in 1881. I vividly remember a conversation I had with him at the Crown Iron Works, in Glasgow, over the results I had obtained from one of my early gas engines. I had then come to the conclusion that the "Otto" cycle as ordinarily operated was a cycle of constant efficiency, and I explained this to Lord Kelvin. He had not followed such cycles, and his view then was that no such cycle could exist, because he thought it was contrary to the second law of thermodynamics. Some idea of this kind has been held by many scientific men, and has prevented the minute investigation of imperfect cycles of different kinds, because of the feeling that the whole question of efficiency was entirely settled by the nature of the temperature limits; that is, by the maximum and minimum temperatures at the disposal of the engineer. It is true that these values, as has been shown, must always determine the extreme limit of possible efficiencies between certain temperatures, and in cycles of constant efficiency the particular efficiency of the cycle is always less than the efficiency of a Carnot cycle engine working between the same limits of superior and inferior temperature. The investigation, however, of these imperfect cycles is much more difficult than the broad investigation of the general thermodynamic laws, because it requires accurate knowledge of the properties of the working fluid dealt with under conditions rendering observation extremely difficult.

The modern internal-combustion motor is the successor to the air engine so fully discussed by eminent engineers of fifty-five years ago; and the forebodings of even so eminent a man as Faraday as to its ultimate success have proved unfounded. Great difficulties have been encountered and many discrepancies have had to be explained, but a minute study of the nature of the working fluid has rendered it more and more possible to calculate the efficiencies to be expected under practical conditions. At the present time we can deal with almost any cycle or any working fluid with some fair approximation to an accurate result. Much work, however, is required before all problems of the working fluid can be said to be solved with regard to any heat engine. Indeed, it may be said that under modern conditions of the use of steam even the properties of the working fluid—steam—have not yet been satisfactorily determined. The mere question of specific heat, for example, of steam and its variations with temperature and pressure is now under review, and important experiments are in progress in Britain and on the Continent to determine those properties. The properties of the working fluid of the internal-combustion motor are also the subject of earnest study by many Continental and British investigators. Notwithstanding all the perplexities involved in the minute study of the imperfect heat cycles, we are in a very different position to-day compared with the engineer of 1853. We know all the broad laws as to the conversion of heat into work or of work into heat; and, numerous as are the problems yet to be solved, we at least profit by the guiding light set out for us by Kelvin, Joule, and Rankine.

Digitized by Google

Sir WILLIAM WHITE, in moving a vote of thanks for this interesting address, said that it showed under what difficulties engineers were working fifty-five years ago. He was glad that the President had referred to the work of Prof. Rankine (whose pupil he was), and whose work combined in a remarkable way both theoretical knowledge and its practical application.

Mr. DUGALD CLERK, in replying, said he wished to make it quite plain that he did not wish to appear to be casting any slur on the engineers of fifty years ago when he stated that as far as thermodynamic engines were concerned, they were working with machines that they did not understand. He would go further than that, and would state that it was the duty of the engineer to construct what was required, if he was able, without waiting until he thoroughly understood the theory of his machine; in fact, this was generally the order in which things had been accomplished. The engineer produced a machine that worked, and then the inquiring or scientific mind came along and ascertained how it worked.

Steam Turbines and Turbo-generators.

Mr. GERALD STONEY (of Messrs. C. A. Parsons & Co.), who read a Paper on "Recent Advances in Steam Turbines," said very rapid development of the steam turbine, both on land and for marine propulsion, had taken place since he read a Paper on the subject at the B.A. meeting at York two years ago. Eight years ago the largest steam turbine on land was 1,000 kw., and this was considered an immense machine at the time; now there are large numbers ranging from 5,000 to 8,000 kw. running and under construction.

Leaving out of consideration the Laval turbine with a single reaction wheel, which requires gearing and is impracticable for large sizes, he divided steam turbines into two classes :—

Firstly, the Parsons turbine, in which there is both action and reaction, and the expansion takes place equally in the moving and fixed blades; and secondly, those in which the whole of the expansion takes place in the fixed blades, the velocity of the steam being taken up without expansion by the moving blades. This latter class can then be sub-divided into those in which at each stage there is only a single row of moving blades as in the Rateau and Zoelly turbines, or one in which there are several rows of moving and fixed blades in each stage, which take up the velocity without any additional expansion, as in the Curtis. There are again various combinations, consisting of mixtures of one or more classes, but none of these have as yet been manufactured to any large extent. The oldest type, and one which is more in use than any other, is the Parsons, but in America the Curtis has been manufactured in large numbers, and on the Continent the Zoelly, Rateau, and A.E.G., although both in America and on the Continent Mr. Stoney claims that the Parsons has taken a leading position.

Turbo-Generator Design.—Hand in hand with the development of the steam turbine, Mr. Stoney continued, has gone the development of the various machinery to be driven by it, and in this direction electrical machinery has been prominent. For many years continuous-current turbo-dynamos were looked at askance by engineers on account of commutation troubles, for it is easy to see that the ordinary constants applicable to slow speed dynamos to secure sparkless commutation are far exceeded when the speed is raised to that of turbine-driven dynamos. On this account it was early seen that some sort of compensating winding to improve the commutation and compensate for the reaction of the armature was necessary. Commutating poles alone have not proved satisfactory in practice, there being nearly always considerable difficulty in securing good commutation with them, and as a consequence commutating poles combined with compensating windings—the commutating poles giving the reactance voltage necessary for commutation and the compensating winding compensating for armature reaction—have been adopted by many firms. But even better commutation can be secured by a compensating winding alone, in which the ampere-turns of the compensating winding exceed the ampere-turns of the armature to such an extent as to give a commutating field in the gap between the pole-pieces.

Such compensation winding is generally chiefly concentrated on the pole-pieces, and is made, Mr. Stoney said, with from 2 to $2\frac{1}{2}$ times the number of ampere-turns of the armature, in order both to compensate for leakage and to give a good commutating field; and since this method of compensating has no iron commutating pole, it has the advantage that there is no self-induction to cause time lag at sudden changes of load, and, as the field of the gap between the poles is entirely in air it instantly responds to changes of current in the compensating winding, and thus the sparking found when there is a sudden change of load with commutating poles is avoided, and the risk of a flash-over largely reduced. Also since there is no iron to become saturated, the commutating field is always strictly proportional to the load, and thus the trouble due to saturation causing sparking at some loads and not at others is avoided. This advantage is specially prominent where the dynamo is required to give varying voltages and to compensate at any of them without outside adjustment of the compensating windings by diverters or otherwise.

The adoption of these devices has made it possible to make turbo-dynamos of large size, and now as much as 1,500 kw. is put into a single armature, whereas before such compensating devices were adopted 500 kw. was the maximum, and even then the commutation was anything but satisfactory.

In turbo alternators there is practically now—except for small sizes and low voltages—one standard pattern—that is, a revolving field rotating inside a stator. In the stator there is little variation in design, except in regard to the ventilating arrangements, which have to be very ample on account of the comparatively large quantity of heat to be removed from a small volume.

One point which has received great attention in recent years is the staying of the end windings of such alternators, it having been found that, owing to their great length, when a "short" took place the stresses on the winding were such as to break the insulation and cause disaster. The amount of these forces has been vastly more than was ever anticipated, and if the windings are not thoroughly stayed, such movements may be set up as to cause disaster. In the rotors there are two prominent types, the barrel and the salient pole, and much discussion has ensued as to the advantages of the one or the other. After considerable experience of both, the author says that on the whole he prefers the salient pole type at present. Ample ventilation is much easier to provide for, and improvements made in protecting and supporting the field coils of this type of rotor have resulted in a design giving great reliability with the maximum use of the space available. One improvement has been enclosing every coil in a tight sheath of sheet steel, so that any movement which may take place due to centrifugal force is between the steel sheath and the body of the rotor, and thus the insulation is protected from any rubbing which might cause it to be cut through and consequently to break down.

Voltage regulation of alternators is also of considerable importance, as owing to the inductive load required by induction motors there is a heavy demagnetising effect on the rotor, and consequent drop of voltage when the load rises. Several methods have been proposed for compounding alternators, most of them requiring a separate commutator or moving contacts altering the resistance of the exciter or main windings, but a method of compounding alternators has recently been brought out which is being largely used with good results. In this apparatus the current supplied by the machine is made to act on the exciter field system in such a way as to reduce the leakage, artificially increased in the first instance, and so raise the voltage of the exciter, and increase the excitation of the alternator, so that any desired amount of compounding required can be obtained. This arrangement has been recently described in a Paper before the Institution of Electrical Engineers (see ELECTRICAL ENGINEERING, Vol. III., p. 546).

Exhaust Steam Turbines.—In many parts of the country reciprocating engines are running non-condensing, and it has now been found that the exhaust steam from them is of great value. Such exhaust steam cannot be practically utilised by reciprocating engines on account of the huge size and volume of the cylinders required, but it is quite otherwise with the steam turbine, where the large volumes of the low pressure steam are exactly what are required for the highest economy. These considerations have led to the introduction of exhaust steam turbines, taking steam at atmospheric pressure and exhausting into a condenser. When it is remembered that there is as much power in the steam from atmospheric pressure down to $27\frac{1}{2}$ in. as there is from 150 lb. down to atmospheric pressure, it is easily seen that the power of a non-condensing plant can be doubled by the addition of an exhaust steam turbine and condenser, and in cases where there is not a supply of cooling water, improvements in cooling towers have enabled them to be put up both cheaply and well. In this connection the use of intermittent supplies of exhaust steam, such as that obtained from engines running intermittently, as in rolling-mills or winding-engines at collieries, has received a great impetus by the utilisation of thermal accumulators, in which the intermittent supply of steam is alternately condensed and re-evaporated, so that a constant flow is obtained for use in the exhaust steam turbine.

Mixed Pressure Turbines.—Yet another refinement has been introduced by the use of mixed pressure turbines, in which there is a low pressure part sufficiently large to give full power when working with exhaust steam, and if the supply of this fails, a high pressure part is brought automatically into action using steam direct from the boilers, and thus there is economical

Digitized by Google

running, whether the reciprocating engines supplying the exhaust steam are working or not.

Condensing Plant.—In all turbines the question of vacuum is a very important one, and various improvements have been made in condensers to enable high vacua to be obtained. The importance of this will be seen when it is remembered that in the average steam turbine 1 in. of vacuum is equivalent to from 4 per cent. to 5 per cent. of steam consumption, or, in other words, it may be taken that for every 3° F. by which the temperature due to the vacuum is reduced, a gain of steam consumption of 1 per cent. is made.

In this connection increase of circulating water is very important. A very usual amount is about 30 times, but if this is increased to 45, the gain in consumption is 4 per cent., and if increased to 65 times a further gain of 2 per cent. is made. As a rule, extra circulating water can be pumped without much difficulty, the extra power required for this being very small. but generally the temperature of the inlet to the condenser is fixed by the supply of water available.

The great desirability then in a condenser is to obtain the temperature due to the vacuum as close as possible to that of the water leaving the condenser, as, of course, the maximum vacuum possible is that due to the temperature of this water. In ordinary condensers it is generally found that this difference amounts to 20 to 25° F., and among the various arrangements to reduce this may be mentioned dry air pumps, and also the arrangement of baffles and pumps in the "contraflo" condenser. But a method which has been very satisfactory in practice is what is called a "vacuum augmentor," which is simply a small jet of steam drawing the air and vapour from the condenser, and delivering it through a small auxiliary condenser to an ordinary air pump, so that while there may be, say, a vacuum of only 27½ in. at the air pump, 28½ in. or 29 in. may be attained in the main condenser. Such an appliance is especially valuable when, as is often the case on board ships at sea, the system has considerable air leaks. With this arrangement the difference between the temperature of the water leaving the condenser and that due to the vacuum can be reduced to about 5° or 6° F., and this when condensing up to 12 lb. of steam per hour per square foot of condenser. As will be seen, this shows an economy in the turbine of some 6 per cent. in steam consumption above an ordinary condenser, and when it is remembered that the steam jet of the augmentor uses only about 0·6 of 1 per cent., or only one-tenth of the steam consumption gained. it is easy to see that a great benefit is derived from the use of such an arrangement.

The remainder of the Paper dealt with marine work.

DISCUSSION.

Prof. FITZGERALD asked what happened in the h.p. end of a mixed turbine when it was being driven only by exhaust steam; did the blades merely churn the air, or did they act in any way as an air-compressor?

Sir WILLIAM WHITE said he thought the turbine that he bought in 1884 or 1885 was the first one Parsons ever made. He bought it to experiment with, as its possible advantages were so obvious. He had had much to do with the application of the turbine to marine work, and was a member of the Cunard Commission that had recommended that turbines should be supplied to the *Mauretania* and *Lusitania*. It was his opinion (and the opinion of many others) that the reciprocating engine must give way to the turbine. Many people were stating that very shortly the steam turbine would have to give way to the internal combustion engine, but he thought, after listening to the address they had just heard on thermodynamics, that much work had yet to be done before that was accomplished. The author of the Paper had not mentioned that in America the Curtis turbine had just been applied to marine work.

In the application of turbines to marine work it must be realised that, with regard to size, progress had been made in one stride, that had taken fifty years in the case of the reciprocating engine. The principal object the designer had in view was to produce a machine efficient as a whole, and with this object in view the efficiencies of turbine itself had to be sacrificed, to a certain extent, to get screw propeller efficiency. The laws governing the efficiency of screws were well known up to 180 or 200 r.p.m., but not above, and it was thought well to keep the turbine speed within these limits.

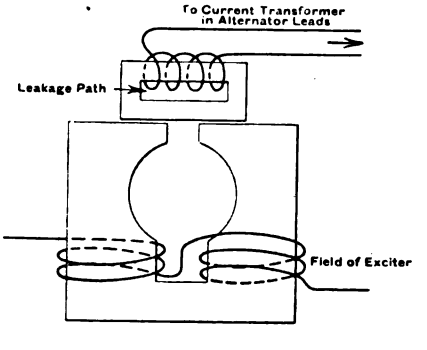
Owing to the much lower speed at which marine turbines had to run, they had not quite so great advantages in point of reduced dimensions as in the case of the stationary turbine. He did not think the size of engines for marine purposes would increase much in the near future; the new Cunarders cost 1½ millions each, and he thought not many companies would care to exceed this. Attention would probably now be concentrated more on reducing working expenses by lightening the coal bill, and he thought, in this respect, the combination of reciprocating and turbine plant would constitute a revolution in marine propulsion.

Mr. PRICE asked for further information with regard to the system of controlling the voltage regulation curve of an alternator by varying the magnetic leakage in the exciter.

Mr. WORBY BEAUMONT made some remarks emphasising certain points referred to in the Paper, particularly the fact that the consideration of propeller efficiencies impaired both the lightness and efficiency of marine turbines; he also referred to the great possibilities for further economies by the combination of reciprocating and turbine plant in one vessel.

Mr. DUGALD CLERK said he thought that he himself had made the first brake-test on a turbine. This was in 1885. The machine ran at 10,000 r.p.m.

Mr. STONEY in replying said, with regard to Prof. Fitzgerald's inquiry, the high pressure end of a mixed turbine, when not being worked with h.p. steam, merely churned the air. There was no compressor action; the blades would have to be shaped differently to effect this. The loss by air churning would be about 5 per cent. of the power developed in the l.p. part. In replying to Mr. Price's query *re* the leakage path method of controlling voltage regulation, he drew the following diagram :—



As the alternating current increases it magnetises to a greater extent the iron in the leakage path, less of the flux in the iron circuit of the exciter passes through this path owing to the increased reluctance, and consequently more flux passes through the armature of the exciter. Mr. Stoney mentioned that the capabilities of the turbine with exhaust steam was being utilised in many places now, particularly in the Newcastle district, where the Supply Company had erected several waste heat plants, utilising the exhaust steam from existing reciprocating plant, and he thought in this respect the turbine was a universal benefactor in that it made it possible to reduce the present waste of coal, our store of which was rapidly disappearing.

Our correspondents mention appreciably an admirable innovation, due to the Dublin Local Committee, by which a system of index boards and telephone connections enable anyone sitting in any section to see at a glance what Papers are being read at that moment in any other section.

Section A. (Physics.)

The Presidential Address to Section A was delivered by Dr. W. N. Shaw, F.R.S., and dealt, as one might expect, with the subject of Meteorology. After the usual vote of thanks, the President announced that M. Teisserenc de Bort, who was to have opened the discussion on the recently discovered isothermal layer of the atmosphere, was unfortunately prevented from attending. The discussion was, however, opened by Prof. A. L. Rotch, and continued by Mr. C. J. P. Cave, Mr. W. H. Dines, F.R.S., Mr. E. Gold, Prof. Trouton, Prof. J. J. Thomson (who subjected the discovery to some rather searching criticism), Dr. Walker (of the Indian Meteorological Office), and Prof. H. H. Turner. Prof. Barrett then delivered an address on "A New Form of Combined Optometer and Entoptoscope," exhibiting and explaining the instrument. A lively discussion ensued, in which Sir W. de W. Abney, Dr. Glazebrook, Mr. Milne, and others took part.

Practical Standards for Electrical Measurements.

In the afternoon Dr. R. T. Glazebrook read the report of the Committee on "Experiments for Improving the Construction of Practical Standards for Electrical Measurements."

The Committee consisted of Lord Rayleigh (chairman), Dr. R. T. Glazebrook (Secretary), Professors W. E. Ayrton, J. Perry, W. G. Adams, and G. Carey Foster, Sir Oliver J. Lodge, Dr A. Muirhead, Sir W. H. Preece, Professors A. Schuster, J. A. Fleming, and J. J. Thomson, Dr. W N. Shaw, Dr. J. T. Bottomley, Rev. T. C. Fitzpatrick, Dr. G. Johnstone Stoney, Professor S. P. Thompson, Mr. J. Rennie, Principal E. H.

Digitized by Google

Griffiths, Sir A. W. Rücker, Professor H. L. Callendar, and Messrs. G. Matthey, A. P. Trotter, T. Mather, and F. E. Smith.

The Committee suggest that their reports from 1862 up to the present time, which are now out of print, might be reprinted as a memorial to Lord Kelvin. It is hoped that the proposed International Congress, to be held in London in October, will settle in a definite manner the few matters relating to the fundamental units which are still outstanding, and will organise a method whereby a close agreement may be maintained among the electrical standards in use throughout the world.

The measurements of certain of the fundamental units, which have been in progress for some time at the National Physical Laboratory, have been brought to a conclusion, and the results were published in three Papers in the "Philosophical Transactions" of the Royal Society.

From the first of these it appears that to a very high degree of accuracy the electromotive force of the Weston cadmium cell, as set up at the National Physical Laboratory, when expressed in terms of the ampere (10^{-1} C.G.S. units of current) and the international ohm is 1·0183$_0$ at a temperature of 17° C.

The second Paper dealt with the preparation of the Weston cadmium cell, and contained a comparison between cells set up at the laboratory and others constructed elsewhere, the general conclusion being that cells can be prepared by different persons in different countries which will agree in E.M.F. to 1 or 2 parts in 100,000.

In the third Paper was an account of a comparison of some six forms of silver voltameters, and it was shown that the silver deposited by a current of one ampere in all these various forms was the same if proper precautions were taken, and amounts to 1·11827 milligrammes per second.

After this work was completed a comparison was made by Messrs. T. Mather and F. E. Smith, by the kindness of Mr. Trotter, between the ampere standard of the Board of Trade and the ampere as realised by the new Ayrton Jones balance at the National Physical Laboratory. The comparison, an account of which appeared in the "Proceedings of the Royal Society," A, vol. 80, 1908, was very satisfactory. It was found that the Board of Trade ampere will deposit silver at the rate of 1·1179$_1$ milligrammes per second, a value which is nearly identical with the number 1·1179$_1$ given by Lord Rayleigh and Mrs. Sidgwick in 1884. Indirectly the E.M.F. of the normal Weston cadmium cell was found to be 1·0187$_0$ Board of Trade volt at 17° C., the Board of Trade volt being defined as the potential difference between the terminals of a resistance of one Board of Trade ohm when one Board of Trade ampere is passing through it.

During the year the ten mercury standards at the National Physical Laboratory have again been set up and intercompared. An account of this work is given in an appendix to the report by Mr. F. E. Smith, and shows that, except in the case of one tube, where there was an apparent change of 3 to 4 parts in 100,000, the resistances agree within one part in 100,000.

Mr. Smith has also compared with the mercury tubes a large series of wire standard resistances, including those made by Matthiessen and Hockin for the B. A. Committee in 1865–67, and various other old standards kindly lent to the Committee by their owners for the purpose. The general conclusion is that all the original coils except two, which are made of platinum, have changed appreciably since they were constructed, though since 1888, during a period of twenty years, for which the coils have been very carefully watched, the changes also in A, B, C, H, and "Flat" have been small. F and G have, however, in the same period changed considerably.

Resistance at 16°·0 in terms of the original B.A. unit (1867).

Coil.	Material.	1867.	1876.	1879-81.	1888.	1908.	Maximum Change.
A	Pt. Ir.	1·00000	1·00377	1·00056	1·00147	1·00122	0·00147
B	Pt. Ir.	1·00029	1·00121	1·00080	1·00104	1·00098	0·00092
C	Au. Ag.	1·00050	1·00141	1·00101	1·00146	1·00173	0·00123
D	Pt.	1·00092	1·00092	1·00092	1·00092	1·00092	0·00000
E	Pt.	1·00152	1·00152	1·00152	1·00152	1·00152	0·00000
F	Pt. Ag.	—	—	1·00016	1·00072	1·00160	0·00144
G	Pt. Ag.	1·00022	1·00030	0·99982	1·00025	1·00175	0·00193
H	Pt. Ag.	1·00020	—	—	1·00042	1·00044	0·00024
Flat	Pt. Ag.	—	—	1·00079	1·00120	1·00125	0·00046

The mean resistance of six other platinum-silver coils, first measured in 1888, appears to have increased since that time by 14 parts in 100,000; and five more platinum-silver coils, first measured in 1894–7, have now a greater mean value by eight parts in 100,000. It would appear also that in many of the variable coils the changes have occurred mainly, if not entirely, at the soft-soldered joints, and with a view of testing this the Committee have authorised the Secretary to open and examine one of the coils.

A comparison has also been made by Mr. Smith of all the manganin resistances in the possession of the Standards Department of the laboratory. The manganin standards are in constant use, and have proved of very great value. They not only facilitate electrical measurements, but they bring them to a far higher degree of accuracy than was formerly attainable. Nevertheless, the variations in these resistances have in many cases been a source of trouble, and attempts have been made, and are being continued, to construct standard coils of manganin which shall remain practically constant in resistance. Since 1905 the manganin standards have been intercompared at least four times every year, and the probable changes have been deduced from occasional comparisons with mercury standards and from tables of difference values, due regard being also paid to the past history of the coils. As an example of the comparisons, the case is taken of seven one-ohm coils which were intercompared in January, April, July, and October, 1906. The observed differences are below.

Coils.	Differences in 1×10^{-5} ohm at 17°·0 C.				
	Jan. 1906.	April 1906.	July 1906.	Oct. 1906.	Maximum Difference.
1690-780	6·82	6·87	7·05	5·93	1·12
1690-2351	2·17	2·35	2·04	1·47	0·88
1690-2483	0·26	0·48	0·26	−0·30	0·78
1690 381	−5·80	−6·05	−5·97	−6·27	0·47
1690-L·17	15·63	13·41	12·69	11·80	3·83
1690 L·18	16·69	16·05	15·54	14·92	1·67

The mean difference in the values of all the manganin coils for 1908 and 1903 is 12·6 parts in 100,000. The oldest coils are about seventeen years old, others are about thirteen and eight years old, and the remainder from five to six years old. In general, Mr. Smith has found that the older the coil the more constant does it appear to be.

The possible causes of the changes in the manganin resistances are classified under the following heads:—Change in structure of the alloy; surface action; humidity effect; change in the soldered joints connecting the wires of high-resistance coils to the current leads; change at the junctions of the potential leads with the resistance standard. Only the first of these appears to explain fully the gradual rise in resistance.

Of the manganin standards examined, says Mr. Smith, some have kept remarkably constant, while others are practically useless as standards. It must not be concluded, he adds, that all manganin resistances are subject to such changes. Drs. Jaeger and Lindeck have shown that the manganin standards of the Reichsanstalt keep very constant, and the manganin coils at the Bureau of Standards also appear to be of a fairly constant type, though subject to considerable cyclic changes owing to variable atmospheric humidity.

At the Conference on Electrical Units, held at the Reichsanstalt in 1905, it was suggested that the Jena glass 59^{III} was, from its good elastic properties, the best glass to employ for mercury resistances, and accordingly efforts have been made to get some suitable tubes. Five tubes have recently been secured, after great difficulty, which will probably do for standards, but the difficulty of drawing them is a serious obstacle to their use. A number of tubes of French glass, "verre dur," are also on order.

The grant of £50 made to the Committee at Leicester has been spent in great part in the purchase of materials for the Weston cells and the silver voltameter research, and in obtaining suitable tubes for use for standards of resistance.

Progress has also been made during the year in the design of the Lorenz apparatus, to be given by the Drapers' Company, and the manufacture of the bed and the heavy-metal work has been entrusted to Messrs. Armstrong, Whitworth & Co., who have kindly undertaken it. The marble cylinders required have been deliverd at the National Physical Laboratory.

Preparations for the holding of an International Congress on Electrical Units in London in October next are well advanced, and specifications dealing with the international ohm, the international ampere, and the Weston cadmium cell, which have been prepared at the National Physical Laboratory, after consultation with other workers to serve as a basis of discussion at the Congress, are given below with a view of making them known.

Specifications for the Practical Realisation of the Definitions of the International Ohm and International Ampere, and Instructions for the Preparation of the Weston Cadmium Cell.

The present specifications are intended mainly to serve as a guide to the standardising institutions of the various countries in order to obtain, as far as possible, complete agreement in the units of electric measurements. Certain instructions, such as the purification of mercury, have therefore been omitted,

Digitized by Google

but all which is thought to be essential for an exact reproduction of conditions is still included.

The International Ohm.

The international ohm shall be equal to the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 14·4521 grammes in mass, of a constant cross sectional area, and of 106·300 centimetres in length, arranged in accordance with the following specification.

The column of mercury shall be of circular section, or nearly so, and shall be contained in a tube of suitable glass which has been carefully annealed. The tube shall be straight to the eye, and the maximum variation in its area of cross section shall not exceed 2 parts in 100. The tube is to be carefully calibrated, and the correction for its conicality determined.

In determining the weight of mercury contained by the tube when filled at the temperature of melting ice, the column of mercury is to be bounded by planes at the terminal cross sections of the tube. The tube should not be unduly heated, and it should be filled with mercury by exhaustion of air.

The axial length of the tube should be measured at 0° C. if possible, otherwise the coefficient of expansion of the glass should be determined and the axial length of the tube at 0° C. calculated from axial measurements made very near to that temperature. To facilitate measurements of the axial length, the ends of the tube should be ground very slightly convex.

For the electrical measurements the end of the tube are to be connected to spherical bulbs of glass, the slightly convex ends of the tube forming, very nearly, portions of the internal spherical surfaces of the bulbs. Each bulb is to be provided with a current and a potential lead, the point of entry of the former, and an end of the tube being at opposite ends of a diameter of the bulb. The potential lead shall be situated in a plane midway between the point of entry of the current lead and the end of the tube, and at right angles to the line connecting them.

Contact with the mercury shall be made by means of platinum wires.

The diameter of a bulb is to be from 30 to 33 times the diameter of the terminating section of that end of the tube to which it is connected.

If L is the axial length in centimetres of the mercury column contained by the tube at 0° C., W the weight of the column in grammes, and μ the correction for the conicality of the tube, the resistance of the column at 0° C. is

$$\mu \frac{L}{(106{\cdot}300)^2} \cdot \frac{14{\cdot}4521}{W} = 0{\cdot}001278982\, \mu \frac{L^2}{W} \text{ international ohms.}$$

When the spherical bulbs are fitted to the ends of the tube and the whole filled with mercury, if r is the mean radius of the tube and r_1, r_2, the mean radii in centimetres of the terminal sections, the resistance at 0° C. between the potential leads is

$$0{\cdot}001278982 \frac{L^2}{W}\left\{\mu + 0{\cdot}80 r^2 \left(\frac{r_1 + r_2}{r_1 r_2}\right)\right\}^* \text{ international ohms,}$$

correct to 1 per cent. of the added resistance

$$0{\cdot}001278982 \frac{L}{W}\left\{0{\cdot}80 r^2 \left(\frac{r_1 + r_2}{r_1 r_2}\right)\right\}^*$$

The electrical measurements are to be carried out at 0° C., the tube and spherical vessels being surrounded by melting ice and about 15 centimetres below the upper surface of the ice. The connecting wires employed for the current and potential leads must be thin, the flow of heat through them to the mercury being insufficient to warm the mercury as to produce appreciable error.

The insulation resistance between the mercury column and the ice surrounding the tube must not be less than 10,000,000 ohms.

The current employed in comparing the mercury resistance with other resistances shall be limited by the condition that the mercury shall not be warmed sufficiently to produce appreciable error.

The mean of at least five tubes must be taken to determine the value of the mercury unit.

The mean of at least three fillings shall be taken as the value of the resistance of a tube.

Specification for the Practical Application of the Definition of the International Ampere.

Conditions under which silver is to be deposited to measure currents from 0·5 to 8 amperes :—

The solution shall consist of from 15 parts to 25 parts by weight of pure crystallised silver nitrate in 100 parts of distilled water free from chlorine. It shall be used for one determination of current only.

In cases in which it is desired to measure a current of about 1 ampere the anode shall consist of a disc or plate of pure silver about 60 square centimeres in area and 3 or 4 millimetres in thickness. It is supported by a silver rod riveted through its centre. The anode shall be inserted into a cup of filter paper separately supported.

The kathode shall consist of a platinum bowl about 10 centimetres in diameter and 7 centimetres in depth.

About 300 cubic centimetres of the silver-nitrate solution are to be placed in the kathode bowl, and the anode is to be supported near the top of the solution and is to be just covered by it. Not more than from 7 to 10 grammes of silver should be deposited.

(For the measurement of smaller currents, say from $\frac{1}{4}$ to $\frac{1}{3}$ ampere, a bowl holding about 60 cubic centimetres of solution may be used, the anode being proportionately reduced in size and from 2 to 3 grammes of silver being deposited.)

The deposit should be rinsed with distilled water free from chlorine until the addition of a drop of neutral solution of sodium chloride in water, to the wash water, produces no milkiness. The kathode bowl is then nearly filled with distilled water and left for at least three hours; it should be rinsed three times, the last of these wash waters remaining in the bowl for ten minutes. This last wash water should give no milkiness when added to a neutral solution of sodium chloride in water. The deposit is to be dried in an electric oven at a temperature of about 160° C.; it is placed in a desiccator to cool, and is afterwards weighed.

The mass of the deposit, expressed in grammes, divided by the number of seconds during which the current has been passed and by 0·001118, gives the mean current in amperes.

Preparation of the Weston Cadmium Standard Cell.

The cell has mercury for its positive electrode, and an amalgam consisting of from 12 to 12·5 parts by weight of cadmium in 100 parts of the amalgam for its negative electrode. The electrolyte consists of a saturated solution of cadmium sulphate, and solid cadmium sulphate is contained within the cell. A paste, consisting of solid mercurous sulphate, mercury, and solid cadmium sulphate, rests on the positive electrode.

For the positive electrode, pure distilled mercury should be used.

The amalgam may be made either by electrodeposition or by mechanical mixing. It should be fused and freed from oxide by washing with dilute sulphuric acid.

For the preparation of the cadmium sulphate crystals and solution, commercially pure recrystallised cadmium sulphate should be dissolved in pure distilled water so as to form a clear saturated solution. Evaporation at about 35° C. is then allowed to proceed, when crystals separate from the solution. The crystals are washed with successive small quantities of distilled water, and part of them is dissolved in distilled water to form a saturated solution. The solution should be neutral to congo red.

The mercurous sulphate should be quite pure, and its crystals should not be so small as to have an abnormal solubility or so large as to be inefficient as a depolariser. The following is an example of a method for preparing the salt satisfactorily :—

Add 15 cubic centimetres of pure strong nitric acid to 100 grammes of pure mercury, and place on one side until the action is over or nearly over. Transfer the mercurous nitrate thus formed, together with the excess of mercury, to a beaker containing about 200 cubic centimetres of dilute nitric acid (1 volume of acid to about 40 volumes of water); a clear solution should result. Prepare about 1 litre of dilute sulphuric acid (1 volume of acid to 3 of water), and while the mixture is hot add the acid mercurous nitrate solution to it. The solution should be added as a very fine stream from the narrow orifice of a pipette, and the mixture violently agitated during the mixing. Mercurous sulphate is precipitated. Decant the hot clear liquid and wash the precipitate twice by decantation with dilute sulphuric acid (1 volume of acid to 6 of water). The precipitate should then be filtered and washed three times with dilute sulphuric acid (1 to 6), and afterwards 6 or 7 times with saturated cadmium sulphate solution to remove the acid. The mercurous sulphate should then be flooded with saturated cadmium sulphate solution and left for one hour, after which the solution is tested with congo red paper. In general no acid will be detected, and if so the mercurous sulphate is ready for use.

To set up the cell the H form of vessel is the most convenient. The platinum wires inside the vessel should be amalgamated by passing an electric current to each in turn through an acid solution of mercurous nitrate. The vessel must afterwards be washed out twice with dilute nitric acid and several times with distilled water; it must be free from stains and scrupulously clean; it is dried by the application of heat. The amalgam is fused and its surface flooded with very dilute sulphuric acid; sufficient of it to cover the amalgamated platinum wire completely should then be introduced into one of the limbs of the H vessel. To free from acid the amalgam may be remelted and washed with distilled water. Into the other limb of the vessel sufficient mercury is introduced to cover the amalgamated platinum wire completely. Then the paste, finely powdered crystals of cadmium sulphate, and saturated cadmium sulphate solution are added in the order named and the cell sealed.

* The end correction factor is given in these formulæ as 0·80: this value is, however, subject to amendment.

Its electromotive force at 20° C. is $1{\cdot}018_5$ volt.

The electromotive force at any other temperature (t) may be obtained from the equation :—

$$E_t = 1{\cdot}018_5 - 0{\cdot}000038\,(t-20) - 0{\cdot}00000065\,(t-20)^2,$$

the limits of temperature being—(these have not yet been fixed).

DISCUSSION.

Principal GRIFFITHS (Cardiff) asked whether any care had been taken to get pure platinum for the coils referred to on p. 390. The temperature coefficient, as shown, was rather low.

Prof. J. J. THOMSON said it seemed to him more a matter of connections than of material, as the platinum silver alloys figured both among the best and the worst standards.

Dr. GLAZEBROOK said that the platinum standards dated from 1865 and 1867, and were presumably as pure as could be got at that time, and possibly better than the more recent ones. The wire resistances had the advantage of a low temperature coefficient, but thermoelectric disturbances could only be eliminated by using mercury.

The Committee asked for a renewed grant of £100 to prosecute the researches, and this was referred to the Committee of Recommendations.

The Educational Science and Chemistry Sections.

In his Presidential Address to the Educational Science Section, Prof. MIALL put in a plea for useful knowledge as against mere book-learning, and for the use of scientific method in acquiring it. Referring to technical education, he said :—

Technical education may be pursued in at least three ways : (1) We may seek to qualify the pupil for his calling by a thorough training in some science or art, and then, by the application under the guidance of an expert, of that science or art to a particular industry. The experience of at least two generations seems to show that this method is really effective; it does what it professes to do. (2) The second method aims at no more than supplying information directly applicable to the industry in question. Surely this is the least profitable of the three. The information is not accurately lodged, either in the memory or in the note-books of the students; it soon becomes obsolete in consequence of the advance of knowledge; and it does little to cultivate intelligence or the power of doing. Where intelligence and the power of doing already exist, mere information may be valuable, but the best storehouse of information is the printed book. (3) Lastly, we may aim at nothing more than facility by repetition. Such practical arts as reading, writing, drawing, needlework, and cookery are largely acquired by imitation and constant practice. Skill in these arts is a tool, whose profitable application depends much upon the intelligence and enterprise of the possessor. Independent attempts to meet difficulties, friendly criticism of these attempts, questioning about the causes of failure, are the expedients which a wise and experienced teacher, ever at hand, would employ. Such a teacher is, of course, rarely to be had, but is now and then found in a sensible mother. Perhaps the best substitute for the sensible mother would be plain, practical lessons on elementary science, such as the Edgeworths, Dawes, and Henslow used to give.

In his Address to the Chemical Section, Prof. F. S. KIPPING attributed the unsatisfactory state of the chemical industries in this country to the erroneous views which were held as to the functions and the training of a works chemist, and advocated an extension of the present period of training and the making of research work compulsory as far as possible.

FRIDAY, SEPTEMBER 4TH.

Section A divided into three departments : (a) mathematics, (b) general physics, (c) cosmical physics and astronomy. Departments (a) and (c) met at 10 a.m., while the meeting of the general physics department was postponed till 11.30 in order to allow its members to take part in the discussion on the report of the Committee on "Gaseous Explosions" in the Engineering Section. The Chemical Section also took part in this discussion.

The Committee consisted of Sir W. H. Preece (Chairman), Mr. Dugald Clerk and Professor Bertram Hopkinson (Joint Secretaries), Professors Bone, Burstall, Callendar, Coker, Dalby, Dixon, Hele-Shaw, Smithells, and Watson, Dr. Harker, Lieut.-Colonel Holden, Dr. Petavel and Captain Sankey. They were appointed for the investigation of gaseous explosions, with special reference to temperature, and this is their first report. To engineers the investigation of gaseous explosions is chiefly of interest because of its bearing upon the theory of the internal combustion engine, and the Committee have hitherto considered it mainly from this point of view.

The first part of the report deals with the measurement of the internal energy and specific heats of gases at high temperatures, and the second part with the measurement of these high temperatures. The previous work done in this direction is summarised and reviewed, and additional experiments carried out by members of the Committee are described. The report is of considerable length, occupying 33 pages.

Nothing of special electrical interest occurred in the mathematical department, the Papers being the purest of pure mathematics.

The department of General Physics attracted a large audience on account of the communications announced from Sir William Ramsay, Sir James Dewar, and Professor Rutherford.

Radio-activity.

Sir WILLIAM RAMSAY, K.C.B., F.R.S., read a Paper entitled "Do the Radio-active Gases (Emanations) belong to the Argon Series?" He endeavoured to assign positions in the periodic system to the emanations of thorium, radium, and actinium. The known elements of the Argon Series, with their atomic weights, are : helium, 4; neon, 20; argon, 40; krypton, 83; xenon, 130. The further atomic weights to be expected are 172, 218, and 262. The atomic weight of radium being 227, that of radium emanation is mostly likely 218. The unassigned numbers, 172 and 262, may belong to either thorium or actinium emanation. The author was inclined to assign the value 172 provisionally to thorium emanation, and 262 to actinium emanation. In the vertical column the radium series would be : Bismuth 208, (unknown 215), (unknown 217); radium emanation, 218, (unknown 223), and radium 227. A similar vertical column of somewhat lower atomic weights must then include 172 thorium emanation. The whole of the elements of that column would then probably be very unstable, which would account for their being as yet undiscovered.

In the discussion which followed,

Prof. RUTHERFORD said he admired Sir Wm. Ramsay's trust in the periodic system, which he personally did not share. If the α-particles are helium atoms of atomic weight 4, the genesis of radium might be represented as follows :—

Uranium 238·5
-2α : Ionium, 230·5
$-\alpha$: Radium, 226·5.
$-\alpha$: Radium emanation, 222·5.

and so on, down to lead, 206·5. The value, 222·5, for the atomic weight of radium emanation was not far from Ramsay's 218. No very accurate results could be got from diffusion experiments. He very much doubted the value 262 for actinium emanation, being rather inclined to regard actinium as a side-branch of the radium genealogy. He hoped to clear up the matter within a year by determining the relative number of α-particles emitted by the various bodies.

Sir OLIVER LODGE said he had followed with much interest the gradual demonstration of the remarkable fact that these emanations were actual chemical substances.

Mr. BUSS was surprised to hear that diffusion would shed little light on atomic weights. He had recently compared the emanations of thorium and actinium by that method, and found that of actinium distinctly lighter.

Sir WILLIAM RAMSAY pointed out that Prof. Rutherford had left out of account the production of neon. Would that not "upset the coach"?

Prof. RUTHERFORD : I am certain of the production of helium, but I regard the production of neon as anything but certain.

Mr. W. MAKOWER read a Paper on "The Number and Absorption of the β-particles Emitted by Radium," in the course of which he described the special precautions taken to eliminate secondary radiation. He found the number of electrons emitted by radium C in equilibrium with one gramme of radium to be 3×10^{10} per second, or rather less than previous values. He concluded that no β-particles are deflected or "scattered," but either totally absorbed or transmitted in the original direction.

Prof. RUTHERFORD said the experiments described gave a method of arriving at the comparative number of β-particles and α-particles emitted. The simplest supposition was that the numbers were equal. He agreed as to the absence of scattering.

Prof. MACCLELLAND said that recent work showed a distinct scattering in the direction of the reflected ray. This scattering was quite distinct from secondary radiation, which proceeded equally in all directions.

Prof. J. J. THOMSON said there was absolutely no doubt that β-particles were scattered by metals. There would be no absorption but for that. He described Crowther's experiment, carried

Digitized by Google

out at the Cavendish Laboratory, in which the ionisation was measured in the direction of a straight beam of β-rays traversing a thin metallic film, and also outside the beam. About nine-tenths of the ionisation was outside the beam.

Prof. WILSON hazarded the guess that α-particles were positive electrons about 1,000 times smaller than β-particles.

Sir OLIVER LODGE wished a distinction to be made between absorption by conductors and by non-conductors. Scattering would naturally be expected in metals, and the curve of absorption should show a parallelism with the curve of opacity. He would like to ask Prof. Thomson if there was any analogy between his recent resuscitation of the corpuscular theory of light and the behaviour of β-rays, which were absorbed according to the same sort of law.

Prof. THOMSON said he preferred to answer that question privately.

Mr. MAKOWER, in replying, said he did not claim that his experiments were quite conclusive. All he maintained was that when β-rays are stopped they are stopped suddenly.

MONDAY, SEPTEMBER 7TH.

In the Engineering Section three Papers were discussed simultaneously, one by Capt. H. R. Sankey, dealing with the utilisation of peat, the second by Mr. J. Emerson Dowson on producer gas, and the third by Mr. Philip W. Robson on suction gas plants.

Peat.

The following is an abstract of the Paper by Captain H. R. Sankey, on "The Utilisation of Peat for Making Gas or Charcoal with Recovery of By-Products":—

The much-discussed subject of the utilisation of peat has during the last few years been revived owing to developments in gas producers and in gas engines, and at the moment it is of considerable interest in Ireland in connection with the Bill which has been promoted in Parliament to obtain powers to produce gas from peat, to use this gas for generating electricity by means of gas engines and dynamos, and to distribute electric power to works which will probably be established in the immediate neighbourhood of the power station and throughout a certain prescribed district. It is proposed to put the power station alongside the Grand Canal, not far from Robertstown, about 25 miles from Dublin.

Previous attempts to utilise peat for power failed because they were based on drying the peat, so as to contain no more than 25 per cent. of water, and in some cases the expense of "briquetting" was incurred; the peat was then transported to the place where power was required and burnt in steam boilers fitted with specially designed furnaces. Such peat could not compete with coal; moreover, the valuable by-products were not recovered.

In the proposed scheme the peat will only be partially dried—that is, will still contain 60 per cent. of water; it will be used on the spot to make gas, so as to get the benefit of the great thermal efficiency of gas engines and to save the cost of carriage. The by-products will be recovered, the profit on which will at least cover the cost of getting and drying the peat. It will be possible to supply power to works in the immediate neighbourhood of the power station as cheaply as can be done from water-power. Many of those industries which are dependent upon cheap power will undoubtedly be attracted.

Great progress has been made in Germany in the utilisation of peat. Although no complete electric-power undertaking is at present working on the above lines, all the various links in the chain are separately and successfully in operation; many of these links have been "Made in Germany," why should not the complete chain be put together in Ireland?

There are several methods of getting and drying peat. Apparently, the most suitable, when it is desired to obtain peat nearly all the year round, is to dig with a grab, and pass the peat through a Dornberg press. The peat then rapidly dries to 60 per cent., except in very wet weather in the winter, and to tide over this period a reserve of peat must be accumulated.

The producers used for making gas from peat are similar to those used with bituminous coal, but they are larger in dimensions for the same power. The gas issuing from the producers passes through the recovery plant, thence to the gas engines. The gas in passing through the recovery plant is cleaned in a very perfect manner, and therefore troubles due to tar and dust are entirely obviated.

Sulphate of ammonia is the principal by-product. The amount obtained depends on the percentage of nitrogen in the peat. The proposed power station at Robertstown will be capable of making 3,000 tons of sulphate per annum.

The other important by-products are acetate of lime, methyl alcohol, and tar containing paraffin wax and oils. An excellent waggon grease can be made from the tar, the output of which at Robertstown ought to be about 2,000 barrels per annum. The monetary value of these by-products will be about equal to that of the sulphate of ammonia.

An excellent charcoal can be made from peat, instead of gas, together with the by-products enumerated above, and the process has been in operation near Oldenberg for over ten years. The most up-to-date factory, however, is at Beuerberg, near Munich, and it has been at work for three years. The charcoal obtained from peat is of excellent quality, and can be used to advantage to replace wood charcoal. It is used in large quantities in Germany in connection with the manufacture of steel.

Producer Gas.

Mr. J. EMERSON DOWSON, in his Paper on "Producer Gas," said that his first Paper on the subject was read at the York meeting of the Association in 1881, and after a lapse of over a quarter of a century he thought it might be useful to take some account of the progress which had been made, and to offer a few passing remarks which practical experience suggested.

The first internally-fired gas producer was devised by Bischof in 1839, but little progress was made in our country until the late Sir William Siemens introduced the combined gas producer and regenerative furnace invented by his brother, Frederick Siemens, in 1857. It depended on the syphon action of a long cooling tube which caused an indraught of air to the producer, and made the gas flow to the furnace. In connection with this producer Siemens used various furnaces of special construction, and in all he heated the ingoing air and re-heated the gas by the outgoing products of combustion, the currents being reversed at short intervals. This was his regenerative system, and with it he attained exceedingly high temperatures with a low consumption of fuel. Since then various improvements have been made, the syphon tube has been abandoned, and the reversals of the currents are only used in special cases, as they occasionally lead to troublesome explosions. The more modern practice is to work the producer with a jet of steam at pressure which injects air, and the gas is delivered to the furnace at pressure; the cooling of the gas is thus avoided, and the hot gas flows continuously in one direction from the producer to the furnace. Only the air is heated by the outgoing products of combustion. In this way no unburnt gas can reach the air before the two meet in the combustion-chamber, consequently there is no risk of explosion in the flues. The process is simplified, and the cost of construction and the ground space required are lessened. The success of this type of furnace, Mr. Dowson continued, has been chiefly due to the heating of the air by the waste heat of the products of combustion, and for this useful outcome of theory and practice we are certainly indebted to the brothers Siemens. In this connection he mentioned that he had often been consulted by manufacturers and others who have had the idea that if they converted the coal into gas, in a producer, they could burn the gas with cold air in an ordinary coal-fired furnace, and get the same high temperature as with a coal fire. This is impossible, as about 50 per cent. of the producer gas consists of nitrogen, and the nitrogen content of the products of combustion is also high; the calorific power of the gas is therefore low, while the heat capacity of the products is comparatively high. The flame temperature is consequently low, especially if the gas is burnt with cold air. To attain high temperatures in a furnace with producer gas at low pressure it is not only desirable that the gas should be hot, but it is essential to heat the air, and obviously the most economical way of doing this is with the waste heat of the products of combustion. When worked in this way in a fairly large furnace it is not difficult to attain a temperature of 1,500 degrees Cent. (2,730 degrees Fahr.), and still higher temperatures can be reached if special arrangements are made.

In connection with furnace work, he also referred to Dr. Mond's system of making producer-gas with recovery of ammonium sulphate as a by-product. This plant can only be used on a large scale, and it needs coal containing a rather high percentage of nitrogen, as the formation of ammonia gas is an essential part of the process. A large excess of steam is sent into the producer to prevent the destruction of the ammonia gas, which is afterwards recovered as a sulphate by mixing it with free sulphuric acid. The gas which leaves this plant, after being washed, &c., has about the same calorific power, and about the same flame temperature, as ordinary producer gas. The advantage to the manufacturer is that the by-product reduces the cost of the fuel: but out of this saving he must pay for interest on the capital outlay, and for the wear of a rather complicated and costly plant.

The applications of producer-gas are numerous and varied, but in proportion to the immense amount of heating required in

Digitized by Google

the various industries throughout the kingdom, the author feels that still more progress would have been made if manufacturers and others knew a little more about the subject technically. Often they do not seem to understand the treatment of gas or what can be done with it. For instance, it not infrequently happens that persons who have a gas plant to serve an engine think that they can take a branch pipe off the main to the engine for some heating work, and they then wonder why the flames jump, and why the result is unsatisfactory.

Undoubtedly the greatest development in the use of producer-gas has been with gas engines, especially during the last few years. A gas engine was worked for the first time with producer gas in 1879, the gas being made in a plant devised by the author; it was a small engine, and developed only 3¼ b.h.p. It consumed about five times more producer-gas than it would have consumed of ordinary town gas, although theoretically the comparative consumption of the two gases should have been as 4 :1. This showed that the weaker gas was not used to the best advantage. At the present time its treatment is better understood, and many important modifications have been made in gas engines. The calorific power of producer-gas of this type remains about the same as in 1879, but now it is necessary to use only four volumes of it for one of ordinary town gas. The improvements in the gas engine have been in large measure due to a better understanding of the thermodynamic problems involved. We are chiefly indebted to Mr. Dugald Clerk, for his investigations in this direction, and there are now many skilled workers who are giving close attention to this interesting and important subject.

Until the last few years the producer-gas used for gas engines was generally made with a jet of steam at pressure which injected the air required, but sometimes air at pressure was forced into the producer by means of a fan or blower. The gas made in either of these ways leaves the producer at pressure, and is now generally known as "pressure" gas. In some of the early gas-producers used for furnace work, air was drawn into the producer by suction—notably in the case of the Siemens producer already referred to—and in recent years the idea of working the producer by suction, instead of by pressure, has been reverted to in connection with gas engines. As early as 1862 Dr. Jacques Arbos, of Barcelona, patented a combination of gas plant and gas engine, in which the latter drew gas direct from the producer, and as this was about the time that a good deal of attention was being given to the Siemens suction producer and furnace it is not unlikely that he was inspired by this, and sought to apply the principle of suction from a gas engine. However, it was not a very practical arrangement, and there is no record of its having been actually used. The first to give effect to this idea in a practical way was M. Léon Bénier, of Paris. His first patent was in 1891, and in the early plants he made, the engine had a suction pump at the side of the motor cylinder, which drew gas from the producer and forced it into the cylinder. The combination was carefully tested by Prof. Aimé Witz, but the results were not satisfactory, and the next step of importance was to do away with the pump, and to use the suction of the engine (on the out-stroke of the piston) to draw gas from the producer. Various other modifications in detail, especially as to the way of producing steam, have since been introduced by different makers, and what is known as a "suction plant" is now extensively used. Mr. Dowson emphasised the fact that the chemical reactions on which the production of gas made with steam and air depends are identical in all types of producers. On several occasions manufacturers have spoken to him as though suction-gas were some new discovery; and they seemed rather surprised, if not disappointed, to learn that it was but an old friend in a new dress. He has even seen some engineers' specifications in which the strange and rather contradictory term "pressure-suction gas" is used. The names "pressure" and "suction" gas are not ideal, they are not scientific, but they are conventional terms which have been generally adopted to convey definite meanings; and it will only lead to confusion if these meanings are misunderstood or the terms are wrongly used.

The calorific power of pressure-gas made with a jet of superheated steam is usually considerably higher than that of suction-gas. In the former the percentages of hydrogen and carbon monoxide are higher, while the percentage of nitrogen is lower: and if the gas is to be used for heating purposes in small burners, or in blow-pipes, it is better to use pressure-gas than suction-gas. In many operations it would in fact be almost impossible to use suction-gas, as after the gas had been washed and cooled its flame temperature would be too low, especially if air at pressure were used to burn the gas. But for driving gas engines, suction-gas is extensively used with excellent results, provided the engines are properly adjusted for it. Suction-gas contains a smaller percentage of combustible gas than pressure-gas contains; and although it requires less air for its combustion, the loss from fluid friction is greater, and for these reasons an engine worked by suction-gas develops a lower maximum power than it would with pressure-gas. This loss in maximum power is not important in a small or moderate-sized engine, but it is more serious in an engine of, say, 200 h.p. or upwards, and for a given power larger cylinders must be used for suction-gas. On the other hand, the fuel consumption in a complete pressure-gas plant with an independent boiler is higher than in a suction plant, and its heat efficiency is necessarily lower than that of a suction plant which produces its own steam. If, however, the steam for the pressure plant is raised by the sensible heat of the gas produced, as is often done, the fuel consumption and the heat efficiencies of the pressure and suction plants are alike. We may therefore assume that under these conditions the heat liberated by the exothermic reactions is recovered in each case to about the same extent by the endothermic reactions.

In considering the two types of plant, the author's general conclusions are as follows:—"A suction plant has certain practical advantages—it costs less and occupies a smaller ground space, but the gas made in it is not so strong as in the older form of pressure plant, and in some cases this advantage of the latter is important. The fuel consumption per h.p.-hour, and the labour required, are the same in both types of plant, provided the steam required is raised without an independent boiler. The consumption of water is the same in both types. It is also worth mentioning that where there are several engines to serve, the arrangement of the gas-pipes is greatly simplified, and their cost is proportionally reduced, when the gas can be taken from a small gas-holder instead of from several suction plants."

In engine work, the Paper concluded, there are now hundreds of thousands of horse-power working regularly and satisfactorily with producer-gas. In this connection the gas plant has come to stay, and steam power has a serious rival; in some cases the pressure type is better than the suction type, in others suction is better than pressure. Each has its own province, and in each the consumption of anthracite is now guaranteed not to exceed 1 lb. per b.h.p.-hour under a full or three-quarter load. With low loads the consumption is a little more. For engines or for heating with small burners the best and cleanest gas is made with anthracite, as it does not yield tar; this not only simplifies and cheapens the plant, but it also reduces the cost of labour in working. When anthracite is too dear ordinary gas-coke can be used, provided that it is well carbonised, that it does not contain too much sulphur, and that it is not mixed with pieces of coal. Non-caking bituminous coal is almost invariably used for large furnace work, and there are some plants which make gas from this fuel for engine and other work. But these plants are rather complicated and costly, and they cannot be used for small powers. They require constant attendance, whereas a plant working with anthracite or coke can be left for several hours—what is gained by using the cheaper bituminous coal for small plants is lost by the additional cost of labour, &c. It is probable that in the course of time these drawbacks will be overcome, but for the present anthracite and coke can be used, and with these the adoption of producer-gas continues to advance most satisfactorily.

Suction Gas Plants.

Mr. PHILIP W. ROBSON, in his Paper on this subject, said that in the two years which have intervened since Prof. Dalby first described the suction gas producer before this Association, the demand for such apparatus has shown a steady and continuous growth both in this country and abroad. The Author has selected three typical cases where the load demand and general requirements are widely different, and in each case the figures given represent average ascertained costs over at least a 12 months' period of working, and has tabulated them in Table I. opposite.

The significance of these figures, the author added, will be appreciated from the fact that, if in case A current was taken from a public supply at ½d. per unit, the total cost of same would be £4,708 per annum. As the actual working costs with suction gas are £1,907, the difference between the latter and the cost of electricity at the assumed low rate of ½d. per unit represents a saving of £2,801 in favour of the gas power installation. This saving would entirely defray the initial total cost of the latter in a little over 18 months. He states that in the weaving shed referred to, the engine has been started up punctually every morning without fail, and the only stoppage in 12 months was that due on one occasion to a heated connecting rod brass. In the case of the cement works, rotary

Digitized by Google

kilns are being operated, and the engines are regularly run for periods of from six weeks to two months night and day without stoppage. On the question of reliability, he also quotes the following figures from Mr. Michael Longridge's last annual report :—

Table I.

Ascertained Total Power Costs with National Gas Engines.

	Case A. Cement works.	Case B. Weaving shed.	Case C. Small Factory.
Size of installation in B.H.P.	450·0	300·0	20·0
Average working load, B.H.P.	360·0	220·0	7·8
Total B.H.P.-hours per annum	2,726,000	610,500	21,200
Initial total cost of installation (including foundations	£4,230	£2,640	£250
Total annual charges :	£ s. d.	£ s. d.	£ s. d.
Interest and depreciation.	423 0 0	264 0 0	25 0 0
Repairs and sundries	50 0 0	30 0 0	3 10 0
Fuel	1,298 4 8	135 4 2	15 11 0
Oil	135 3 10	10 0 0	2 0 0
Water (taken from canal in cases A and B)	—	—	7 5 0
Attendance, &c.	423 17 4	135 0 0	12 10 0
Total	2,330 5 10	574 4 2	65 16 0
Total cost per B.H.P.-hour	0·205d.	0·225d.	0·745d.
*Equivalent cost per Board of Trade Unit	0·245d.	0·27d.	0·79d.

* This means that if current were delivered from a public supply to a motor of 90 per cent. efficiency in cases A and B, and a motor of 80 per cent. in Case C, the rate of charges for such current would have to be those stated to give the equivalent cost per B.H.P.-hour also mentioned above. If, however, the standing charges in respect of the motors and electrical installation generally are added, this rate would have to be greatly reduced to equal the gas engine installation in economy.

Rates of Breakdowns.

Steam engines	1 in 8·1.
Electric motors	1 in 8·2.
Gas and oil engines	1 in 12·4.

The following is an abstract of the remainder of the Paper :—

We have been greatly aided in the successful development of these producers through having a suitable fuel at hand in England and Scotland and in several parts of Ireland. Up to the present, for reasons which will be explained later, suction producers have only been made to work on a commercial scale with non-bituminous fuels, such as anthracite and coke, both of which are easily obtainable in the industrial centres of the kingdom. In England, Welsh anthracite was obtainable until two years ago for about 20s. per ton, at which figure there was no difficulty in obtaining the much advertised "10 b.h.p. for one penny" in fuel cost. With the rise in the price of anthracite, gas plant makers adapted their apparatus to work with gas coke, which can be bought at from 10s. to 15s. per ton, and as the consumption of such coke in a well-designed producer need not exceed 25 per cent. more than anthracite for the same power, it will be seen that it is in any case more economical to use it. In Scotland, suitable anthracite can be obtained at from 10s. to 15s. per ton, and the local supplies of anthracite in most of our colonies and in France and Spain are now being successfully used for suction producers, whilst in other countries charcoal is plentiful and comparatively cheap.

The principle of working all suction producers is similar : the gas inlet valve on the engine cylinder is directly connected to the producer, which usually consists of the furnace or generator coupled to a cooling vessel or scrubber. During the suction stroke of the cycle the inlet valve of the engine is opened, and the gas accumulated in the intervening pipes between the engine and the producer is drawn forward into the working cylinder together with a proper proportion of air. A corresponding amount of mixed air and steam flows into the furnace of the producer and reacts there with the fuel, with the result that gas is evolved of an amount equal in volume (after being cooled in the scrubber) to that drawn away. Hence the yield of gas entirely depends upon the suction effect exerted by the engine through the gas inlet valve; the latter being in turn under the automatic control of the engine governor in the extent to which it is allowed to open causes the amount of gas to be automatically regulated to suit variations of load. All the attention that is necessary, therefore, whilst the plant is working, is to keep the generator charged with fuel—an operation occupying from two to three minutes every two hours.

The conditions under which combustible gas is produced in the generator so as to give the best efficiency have been carefully investigated. Obviously, the fuel must be gasified in such a way as to lose a minimum quantity of heat in the producer, so that as large a balance as is possible is available for useful work in the engine. The only burnable gas which can be obtained in the usual way by the partial combustion of the carbon constituents of the fuel is carbon monoxide (CO) as expressed by the equation

$$2C+O_2=2CO, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (a)$$

but the production of this gas is attended by an evolution of 30 per cent. of the heat of the carbon reacted on. Unless this heat were to a large extent recovered the efficiency of the producer would, obviously, be very low, and besides the cumulative effect of a continual liberation of heat in this degree would be to set up a very high temperature in the producer which would tend to the formation of excessive clinker and which would also cause many other difficulties.

A simple practical means of utilising this heat and enriching the gas at the same time is by the method so generally adopted now of saturating or partially saturating the air passing to the furnace with steam. This steam reacts with incandescent carbon in two alternative ways—

$$C+2H_2O=CO_2+2H_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (b)$$

$$C+H_2O=CO+H_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (c)$$

In both of these reactions a combustible gas results, and they both require heat to enable them to take place. This is supplied by the liberated heat just referred to, which results from the direct combination of the oxygen of the air with the carbon of the fuel to form carbon monoxide, and hence, broadly speaking, the degree in which the reduction of steam according to either of the foregoing equations can take place with advantage depends entirely on the amount of heat available from the production of monoxide in the primary reaction according to equation (*a*).

The decomposition of steam in the presence of heated carbon, however, begins at a comparatively low temperature (between 500° C. and 600° C.), and hence if too much steam is used the fire becomes unduly cooled, which is undesirable.

A further advantage which follows from the use of steam is the enrichment of the gas made, for the hydrogen evolved by the reaction (*b*) and the monoxide and hydrogen in reaction (*c*) are combustible gases produced apart from reactions with atmospheric oxygen, which in all cases carries with it four times its volume of nitrogen. This latter is a diluent in all producer gas and passes through the furnace unchanged.

In all suction producers directly connected to the engine and automatically regulated thereby, successful working depends also upon the absence of any serious restriction to the flow of gas from the furnace to the engine cylinder. If there is a restriction for any reason, the weight of charge drawn into the working cylinder of the engine is reduced and a loss of power results which may make all the difference between success and failure. The very simple form of generator and scrubber in the ordinary suction plant using non-bituminous fuel makes it possible to avoid undue restriction; even when gas coke or poor anthracite is used, each of which yields a certain amount of tarry matter and consequently requires the addition of a suitable tar extractor to the scrubber, the suction pressure can be kept sufficiently low to prevent the volume of charge becoming unduly diminished.

Bituminous fuels contain upwards of 30 per cent. of volatile matter, which distils off at such temperatures as are found in the upper part of a suction producer. Now, of these volatiles, 6 per cent. and upwards is tarry matter, which condenses out as the temperature of the gas is lowered in the scrubber and gas mains. These latter would quickly become clogged up, and, in addition, so large a proportion of tar would be carried forward to the engine that the successful working of the latter would be vitiated. It is this tar difficulty which is the chief trouble to be dealt with in making a successful suction producer to work with bituminous fuels, for the addition of extra cleaning apparatus to extract the tar in a sufficient degree would necessarily have the effect of greatly increasing frictional resistance to the passage of the gas from the generator to the engine, and would otherwise destroy that simplicity of arrangement which we have seen to be essential. Attempts have been made to decompose the tar by working the producer on the down-draught principle, which has the effect of compelling the volatiles to pass through the hot zone of the furnace before leaving the producer. By another plan the gas outlet is in the middle of the producer and air is supplied both at the top and at the bottom, the action which is aimed at being to use the upper half of the producer as a down-draught furnace for distilling and fixing the volatiles, while the lower half is supplied with the residual coked fuel and works as an ordinary

Digitized by Google

up-draught furnace. It is, however, extremely doubtful whether a successful solution of the difficulty will be arrived at by either of these two methods. In pressure producers many plans for reducing the tar within the producer by passing the volatiles through the hot zone of the furnace have been carefully tried from time to time, but without a sufficient measure of practical success to warrant the permanent adoption of any of them for use with bituminous steam coal such as is available here. There appears to be no reason for thinking that modifications of these proposals when applied to suction producers will prove to be more efficacious. Calculations given in the Paper suggest a better method for attacking the problem. It is shown that all the sensible heat liberated by the combustion of the carbon of the fuel with the oxygen of the air could be absorbed by the reduction of the steam passing into the furnace along with the air, and that the precise amount of steam which can be reduced depends entirely on the amount of heat which is so liberated. Further, when we account for the whole heat of the carbon in this way and take into full consideration the diluent effect of the nitrogen which is unavoidably present, a gas of sufficient calorific value results for effective use in the engine cylinder. There would, therefore, seem to be no reason why the furnace of the producer should not be devised in such a way that the volatiles are absolutely burnt out after being distilled, the heat of this combustion being afterwards recovered by the decomposition of steam under the conditions already described. By such a method the tar would undoubtedly be eliminated, whilst the efficiency of the system would be high. There are several designers at work on producers of this character, and when the proper proportions and other practical details are understood a considerable measure of success may be hoped for; the simplicity of the cooling and scrubbing arrangements under this system gives good promise of the feasibility of evolving a practical suction plant for use with bituminous fuels. The ordinary plant, however, for gas coke or anthracite may still be expected to hold the field for units up to 100 b.h.p.

The Paper concludes with the following passages:—It is becoming increasingly recognised by leading electrical engineers that it is exceedingly difficult, and in many cases impossible, to supply current for power purposes from central stations at rates sufficiently low to favourably compete with the cost to the consumer if he generates his own power; but as attention has recently been so fully drawn to this aspect of the matter in a comprehensive Paper read before the Institution of Electrical Engineers by Mr. J. F. C. Snell, it is only necessary to refer to it briefly here. Mr. Snell has emphasised the present inability of most electricity undertakings to meet a large demand for power at sufficiently low rates to hold their own with users' own plants, and I understand his remedy to mean the remodelling of central power stations, the writing down of the capital expenditure already incurred in connection with them, and the elimination of independent electricity stations in the smaller towns in favour of a central installation supplying a group of towns.

I think Mr. Snell, who speaks with competent knowledge of electricity undertakings generally, does well to face the position frankly; but in view of such facts relative to the economy and reliability of gas power as I have ventured to refer to here, it will be conceded that there are adequate grounds for the serious doubts which some of us feel as to the wisdom of embarking on the many millions of expenditure which the general adoption of his proposals would entail. The ultimate effect of such proposals, which are chiefly framed with the object of supplying power to factories as distinguished from general electric lighting, would be nothing more than an attempt to do for the power user what he can carry into effect on better terms for himself by the use of gas engines and suction gas producers.

Another important point is that the growing tendency which exists to remove factories out of the large town areas must tend to continually increase the distribution costs of electricity supply, thus making the chances of a margin of profit on any rate which it would be to the advantage of the user to accept even more remote. On the other hand, particular location has little or no influence on the successful and economical working of gas producers.

The following is a report on the joint discussion on these three Papers:—

Mr. CROSSLEY said that Mr. Sankey's paper was very interesting to him, because his company had been experimenting and looking into the case that can be made out for the utilisation of peat. Peat was an ideal substance for producing gas, but it had already been proved that it did not pay to carry the peat, and therefore the plant had to be taken to the peat bogs. The experiments his firm had been engaged in were to answer the questions, could peat be used in a gas producer when it contained as much as 60 per cent. of moisture? and did the peat contain a sufficient quantity of nitrogen to make the collection of ammonium sulphate profitable? He said their experiments had been carried out with a gas plant not specially designed for treating peat, but of the ordinary anthracite type, and the answers they had to make to these questions were, that undoubtedly a good gas can be produced from peat containing as much as 60 per cent. of moisture, and that a large quantity of the peat contained quite enough nitrogen to make the sulphate of ammonium not only a valuable by-product, but actually to pay, by the production of this substance alone. On the bog of Allan in the Kildare district there was a tremendous quantity of peat available; it was right on the banks of the Grand Canal, which offered cheap transit to Dublin and other places. There was also a great quantity of limestone immediately available (with a view to the manufacture of calcium carbide), and anthracite coal could be got from Kilkenny, about 30 miles away. He might say that they would be able to produce electrical energy a great deal cheaper than could be done by large generating stations at the coal pit mouth; in fact, their cost for generating would be about on a par with the large hydro-electric stations. There was no doubt that there were a large number of manufactures at the present time in which the cost of power was the principal item, and in future, instead of as at present their having to go to Norway, Spain, America, and other places to obtain cheap electricity generated from water power, they would be able to get the same facilities on the bog of Allan. Mr. Crossley further stated that they intended establishing a plant capable of dealing with 10 tons of peat per hour, the capital cost of which would be £50,000. The peat experimented with contained 2·2 per cent. of nitrogen, and in their experiments yielded 140 lb. of sulphate of ammonium per ton of dry peat. He believed they would ultimately get better figures than that, and should get 170 lb., *i.e.*, 80 per cent. of the sulphate available; in fact, he did not see why, after further experiments, the whole should not be recovered. He stated that their capital cost of £50,000 could be written off completely in six years, and that they could make a gross profit of £24,000 a year. Going into the cost of the process, he stated that with peat yielding 2·2 per cent. of nitrogen the cost of reducing one ton of ammonium sulphate would be £5 18s., which would sell on the open market at about £11 per ton, but even if they were working with peat yielding 1·6 per cent. of nitrogen or yielding 100 lb. of sulphate per ton of dry peat, it would still be a very profitable investment. The cost of production in this case would be £7 9s. per ton, and, if this was sold at £11 10s. per ton, this would yield a profit of £4 1s., or even if they further reduced the profit to £3 per ton it would return a matter of some £6,000 on the £50,000 outlay. This did not take into account the gas which was produced, part of which could be sold at a very low figure for driving gas engines for the generation of electricity, which, at the price they could offer gas at, would undoubtedly lead to the building up of many industries in the neighbourhood. They could, of course, use the balance of the heat not required for power purposes to help to dry the peat. He stated that Mr. Robson's remarks with reference to the high efficiency of small producer gas plants were most interesting, and it was a well-known and indisputable fact now that in many small plants a horse-power-hour was being generated with the consumption of only ⅝ of pound of coal. With regard to the trouble due to tar when using bituminous coal, Crossleys fan separator worked well and did away with this trouble. He thought that Mr. Robson was rather pessimistic about the use of bituminous coal for suction producers; they had made great progress, and when they had a few plants running, it would soon bring the vendors of anthracite coal on their knees and reduce the ridiculously exorbitant prices which were at present being charged.

Mr. SIEMENS said that Mr. Dowson was not quite right in stating that "the modern practice with producers is to work them with a jet of steam," as if Sir Wm. Siemens had not made this discovery. The speaker distinctly remembered, when working in the drawing office in 1867, drawings of both suction-gas producers and those working with steam jet. He mentioned that since the year 1899 he had had a small 10 h.p. producer gas plant working at his private house, and although his was a comparatively old design compared with those of the present day, he had tested it and found out that it could produce one Board of Trade unit for 20 ounces of anthracite coal. This, of course, included the losses in the gas engine and dynamo. He thought that if makers would again experiment with carrying the gas to the engine in a large and long overhead pipe, in which the passage of the gas would be very slow and in which it would be well cooled, and then collected from this pipe the by-products, good results would be obtained. He stated that he had heard such figures as Mr. Crossley mentioned quoted before on paper, and one disadvantage of quoting such figures was that people had a habit of remembering them afterwards, and might ask, why should we pay £11 per ton for what only costs you £5 to produce? (Mr. Crossley replied to this immediately by stating that the sulphate of ammonium industry was such a huge one that the market would not be brought down by the amount that they would manufacture in Ireland.)

Mr. RIGBY (engineer to Messrs. Crossley Bros.) stated that he did not agree with the practice recommended by Mr. Dowson of working producer gas furnaces at a temperature of 1,500° C., but thought 600° was a much better temperature. With reference to the percentage of steam used in gas producers, he said, of course, it was well known that you could work between the limits of no steam to 2½ tons of steam per ton of fuel, and although, as shown by Mr. Robson, you could get a richer gas by working with a smaller quantity of steam, it required a fairly large amount of steam to prevent clinkering, and there was not much advantage in getting a rich gas if you were getting rid of clinker and ashes containing perhaps 5 per cent. of carbon. He thought 9 lb. of steam per lb. of coal a good rule, and you burnt your fuel better, but, of course, it depended on the fuel; with a good fuel you could work with a higher temperature, but with a bad fuel you must work with a low temperature in order to prevent clinkering. He did not believe in a down-draught type of producer; they worked well for two or three hours, and then usually gave trouble by the fire getting into holes; neither could he agree with the statement that the trouble that prevented the use of bituminous coal was the difficulty of getting rid of the tar. His firm had solved the tar difficulty for the past five years by means of a centrifugal fan arrangement which worked excellently; the real trouble with the bituminous coal was that of caking, and his firm had practically got over this difficulty by a new type of producer in which the fuel was burnt twice. It was first of all passed on to a grate, where it was slowly burnt, and the caking that occurred was broken up mechanically by vibrating the bars. This broken-up caked coal was then fed down into the producer proper, and the gases that came off from the top grate were brought round underneath the second producer furnace and fed into this with jets of steam. The results they had obtained were admirable, but there were a few details that required to be altered before the plant was put on the market.

Mr. SHERLOCK, who said he had had a great deal of experience in the attempts to utilise peat in the past, at last looked forward with pleasure to a practical scheme being formed for the utilisation of peat. As stated by previous speakers, the situation of Robertstown was admirable, and when fuel for gas engines could be produced as a by-product, surely something ought to be made out of the scheme for utilising it for the generation of electrical energy. He stated that, generally speaking, the average depth of a bog was about 15 ft. This was divided into three strata. The top 5 ft. was practically useless except for making peat litter and using the dust for packing purposes; the next 5 ft. produced useful peat for ordinary burning, but it was the bottom 5 ft. that contained the nitrogen. He had had a sample carefully tested, and the results had been practically no nitrogen in the top 5 ft. and 3 per cent. in the bottom 5 ft., therefore he thought it should be realised that before useful peat for the production of sulphate of ammonium was obtained the top 10 ft. had to be cleared away.

Mr. CROSSLEY immediately rose to his feet, and said that their experience after many experiments was perfectly different; it was the top 5 ft. that contained the largest amount of nitrogen, and that there was no necessity to grab up useless peat before good peat could be obtained.

An interesting Paper by Mr. Walter Rosenhain (National Physical Laboratory) was read on "The Study of Breakages." This necessitated curtailing the discussion on the peat and gas Papers.

A Paper by Prof. Ernest Wilson, which we abstract below, was taken as read:—

Light Aluminium Alloys Exposed to the London Atmosphere.

Prof. ERNEST WILSON explained that specimens of certain light aluminium alloys were placed on the roof of King's College, London, in order to investigate the effects of exposure to London atmosphere. The specimens were in the form of wire 0·126 ins. (3·2 mm.) diameter, and were placed on the roof on June 11th, 1901. They were taken down in June, 1908, and their electrical resistance measured. Only one specimen of each alloy was exposed. The deterioration of the copper alloy was found to increase with the percentage of copper. Those alloys containing zinc as well as copper had very much deteriorated, and the breaking load was not higher than that of commercially pure aluminium. The copper-nickel alloy with the highest tensile strength had considerably deteriorated. Those alloys containing a comparatively high percentage of iron showed little deterioration, and their tensile strength was high. Manganese in fairly large proportions increased tensile strength, and had little effect upon durability. An examination showed that the specimens were not badly pitted. The tensile strengths referred to were those taken originally, and no tests have yet been made to ascertain whether there have been any variations in this respect. The increase in specific resistance ranged from 5 to 55 per cent. for different alloys.

THE NEW AUSTRALIAN TARIFF

ON page 432 of Vol. II. of ELECTRICAL ENGINEERING we gave particulars of those sections of the new Australian tariff connected more or less intimately with the electrical engineering and allied industries. At various times since we have given certain amendments, which were the result of representations made on the part of traders and manufacturers. We now have before us the rates of duty and wording of items as finally passed by the Commonwealth Parliament, and as there are important alterations to be recorded in the original proposals, we give at length those portions of the new tariff of interest to electrical engineers.

The Manufacturers' Association of Great Britain has been very active in its efforts to secure some modification of many of the duties first suggested, which were regarded as detrimental to the interests of British industries. That the Association was extremely successful may be judged from the following alterations which were made in the proposed tariffs upon electrical goods. A 25 per cent. duty upon dynamo-electric machines up to the capacity of 200 h.p., static transformers, and induction coils for all purposes, and electric fans was reduced to 20 per cent.; generators for direct coupling to steam turbines will be admitted free, instead of being liable to a duty of 12½ per cent.; electric fittings consisting wholly or partly of metals, viz., switches, fuses, and lightning arresters are free (the proposed duty was 20 per cent.); and high-speed reciprocating steam engines for direct coupling, or directly coupled to generators or pumps, will also be admitted free of duty, whereas it was intended to impose a tariff of 25 per cent. In the new tariff, electrical machinery is gathered into three distinct groups under Division VI., "Metals and Machinery." Previously, electrical machines were scattered over the metals and machinery portion of the tariff, and the alteration in question was made in deference to the wishes of a deputation of manufacturers of electrical machinery who waited upon the Minister of Customs on September 3rd, 1907.

Originally, there was an all-round duty of 12½ per cent. upon electrical machinery entering Australia without any classification, and it may be recalled that a Royal Commission was appointed by the Commonwealth Parliament to inquire into the effect of the new tariff, as it was put forward in the first instance. The following remarks upon electrical goods appeared amongst the conclusions of the Committee:—

That the present duty of 12½ per cent. is too low for protective purposes, too high as a revenue duty, and that an increased duty to a protective standard on certain special lines of electrical machinery and appliances would give a stimulus to the manufacture of electrical machinery and appliances in Australia. That electrical generators, motors, and fans, and other machinery and appliances have been made in Victoria and Queensland under 25 per cent. protective tariffs which were in operation at some period prior to Federation. That owing to the reduction of duties in Queensland the local production of electric fans, motors, and other appliances in that State ceased; thereafter no attempt was made to compete with importations, and firms which formerly manufactured, are now importing these products. That there seems to be no reason why electrical generators and motors, probably up to a high capacity, and certainly up to 500 horse-power, should not in the future be made in Australia, provided the insulated conductors and insulating

Digitized by Google

materials required are admitted free. The parts which could be made in this country are as follows, viz., castings, bedplates, yoke and pole pieces, magnet cores, bearings, slide rails, armature sections, including shaft, core stampings, commutators, brush rocker, and holders. That starting and regulating rheostats, starting switches, and controlling devices for both alternating- and direct-current machinery can be readily made in Australia. That electroliers, electric wall brackets, gas brackets, and gaseliers, globe holders, and adapters, brass pendants and brackets, photometers, incandescent lamps, and gas mantles, reflectors, arc lamps, and globes, testing instruments and meters, should be classed together and subject to the same rate of duty, whether used in connection with gas or electric light.

The Commission recommended an ad val. duty of 25 per cent. on electrical machinery—generators, motors up to the capacity of 500 h.p.; fans, starting and regulating rheostats; ad val. duty of 12½ per cent. on machinery not elsewhere included; 20 per cent. electric and gas appliances.

From the final duties given below it will be seen that the recommendations of this Commission were not adopted absolutely, and we are informed by the Manufacturers' Association of Great Britain that on a number of items where the Commonwealth Government were unable, for various reasons, to reduce the duties on British goods, they met the representations of the Association (in a more effectual way in some cases) by creating or increasing existing preferences.

EXTRACTS FROM AUSTRALIAN CUSTOMS TARIFF, 1908.

All imitations to be dutiable at the rate chargeable on the goods they imitate, unless such rate is less than the rate which would otherwise be chargeable on the imitations.

The term "Iron" includes "Steel."

N.E.I. means "not elsewhere included."

Any article, not otherwise dutiable, composed of a combination of other articles, some of which are dutiable when imported separately, and of others free of duty when imported separately, shall be dealt with as follows:—

(*a*) When the value of the dutiable portion exceeds the value of the free portion, duty shall be charged upon the whole article at the same rate as would be chargeable on that portion of the dutiable portion which, if imported separately, would be liable to the highest rate of duty.

(*b*) When the value of the free portion exceeds the value of the dutiable portion of such article, the whole article shall be admitted free of duty.

IMPORT DUTIES.

Tariff Items.	General Tariff.	Tariff on Goods the Produce or Manufacture of the United Kingdom.
DIVISION VI.—METALS AND MACHINERY.		
142. Lamps, Miners' Safety	Free	
160. Motive Power Machinery and Appliances (except Electric), viz.:—		
(A) Flue-heated Economisers; Mechanical Stokers; Steam Traps; Steam Turbines; Superheaters; Water Purifiers ... ... ad val.	5 per cent.	Free
(B) High-speed Reciprocating Steam Engines for direct coupling or directly coupled to electric generators or to pumps, subject to Departmental By-laws ... ad. val.	5 per cent.	Free
(C) N.E.I. ... ... ad val.	20 per cent.	
176. (D) Coal-cutting machines ad val.	5 per cent.	Free
177. Electrical Machines, Appliances, and parts thereof:—		
(A) Dynamo Electric Machines up to the capacity of 200 horse-power; Static Transformers and Induction Coils for all purposes; Electric Fans... ... ... ad val.	20 per cent.	
(B) Dynamo Electric Machines over the capacity of 200 horse-power ... ad val.	12½ per cent.	
(C) Regulating, Starting, and Controlling Apparatus for all electrical purposes, including Distributing Boards and Switchboards, except Telephone Switchboards ad val.	20 per cent.	
(D) Electric Fittings consisting wholly or partly of metal, viz.:—Switches, Fuses, and Lightning Arresters	Free	
(E) Electric Heating and Cooking Appliances ... ad val.	15 per cent.	10 per cent.
(F) Electric Fittings not containing metal to be dutiable according to material.		
(G) Generators for direct coupling to steam Turbines ad val.	5 per cent.	Free
178. Electrical and Gas Appliances, viz.:—		
(A) Electroliers; Gaseliers; Chandeliers; Pendants; Brackets, Zinc Tubing ad val.	20 per cent.	
(B) Gas meters ... ad val.	5 per cent.	Free
(C) Telephones, Telephone Switchboards and Appliances	Free	
(D) N.E.I. ... ... ad val.	17½ per cent.	10 per cent.
179. Electrical Articles and Materials, viz.:— Accumulators or Storage Batteries; Arc Lamps; Arc Lamp Carbons; Cable and Wire (covered;) Carbon in blocks of 12 square inches and over; Electric Vacuum Tubes; Measuring and Recording Instruments; Prepared Insulating Tape ad val.	5 per cent.	Free
180. Rails, Fish Plates, Fish Bolts, Tie Plates and Rods, Switches, Points, Crossings, and Intersections, for Railways and Tramways ... ... ad val.	15 per cent.	10 per cent.
181. Iron Pipes, Cast and Wrought, n.e.i., and cast-iron fittings for pipes ... ... per ton	40s.	35s.
182. Iron and Steel Tubes or Pipes (except riveted or cast) not more than 6 inches internal diameter; including Flexible Metal Tubes; Galloway and Vertical parallel Boiler Tubes, bent or straight; Water Bore Casings; Wrought and Malleable Iron fittings for pipes; and unpolished metal-cased tubes or pipes	Free	
183. Rolled Iron or Steel Beams, Channels, Joists, Girders, Columns, Trough and Bridge Iron and Steel, not drilled or further manufactured; Shafting, Cold Rolled, Turned, or Planished ... ... ad val.	17½ per cent.	12½ per cent.
193. Anodes, Cathodes, and Hooks for plating purposes ... ad val.	5 per cent.	Free
DIVISION XVI.—MISCELLANEOUS.		
424. Asbestos Pipe and Boiler Covering; Asbestos Mattresses for Boilers ... ... ad val.	20 per cent.	

Electrical Exhibition in New York.—An electrical exhibition is to be held in Madison Square Garden, New York, from October 3rd to 14th, under the auspices of the lighting companies of Greater New York. The exhibition will commemorate the jubilee of the laying of the first submarine cable, of 1858, and the completion of 25 years of continuous electric supply on Manhattan Island. Mr. Thomas A. Edison has taken the honorary presidency, and the vice-presidents are leading men in the industry. One day has been set aside for charity.

Electric Power Transmission in Chili.—According to the *Electrical World*, the Empresa de Traccion y Alumbrado Electricos, of Santiago, is installing a 22,000-h.p. hydro-electric plant at La Florida, whence the electrical energy is to be transmitted to the city over an underground cable at 12,000 volts. This will be sufficient to light and supply power for the works of the city for many years to come. The installation is principally German.

AN AMERICAN SINGLE-PHASE LIFT MOTOR

MOST of the electric lift installations in this country are worked by continuous-current motors, and with this type of motor an excellent speed control can be obtained. However, in districts in which the supply is in the form of alternating current, there is a considerable demand for a good single-phase lift motor with a good starting torque and freedom from sparking. In a recent issue of the *Electrical World*, a single-phase lift motor which has been brought out by the Century Electric Co., of St. Louis, was described. This motor is built in 5, 7·5, and 10-h.p. sizes, and is claimed to have a very high power factor and a reasonably high efficiency.

The motor is a repulsion-induction commutator machine, being in principle of operation substantially equivalent to a single-phase constant-speed induction motor while in starting condition, but it differs from that type of motor in that it is designed to work normally with the commutator in circuit instead of having it cut out. It, however, has a centrifugal device which short-circuits the armature at synchronism, thus placing the motor armature on short circuit for the purpose of limiting the speed when the lift is driving the motor. This device puts the commutator back in service again as soon as the speed has dropped below synchronism by 10 per cent. The commutator is very large for the output of the motor, and this and careful design of the brush-holders are said to have lessened the deterioration of the commutator to the degree obtained with good continuous-current motors.

The curves in Fig. 1 illustrate the starting characteristics of

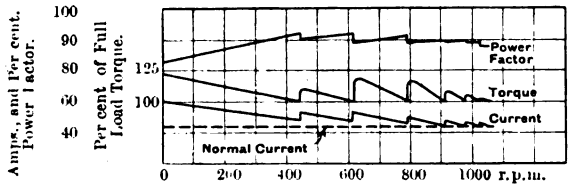

FIG. 1.—STARTING CHARACTERISTICS UNDER NORMAL LOAD WITH CONTROLLER.

this motor when used with a non-inductive controller. The curves were taken from a certain 75-h.p., 1,080 r.p.m., 60-cycle motor, but they are generally characteristic of this line. As will be noted, throughout its entire normal range of operation, the power factor of this motor, while starting with the non-inductive controller, is above 80 per cent., and it rises to above 90 per cent. at certain points.

Fig. 2 shows the operating characteristics of the motor when all of the starting resistance is short-circuited. These curves cover a range of speed from 400 to 1,200 r.p.m., the latter being the synchronous speed of the motor. The ultimate starting

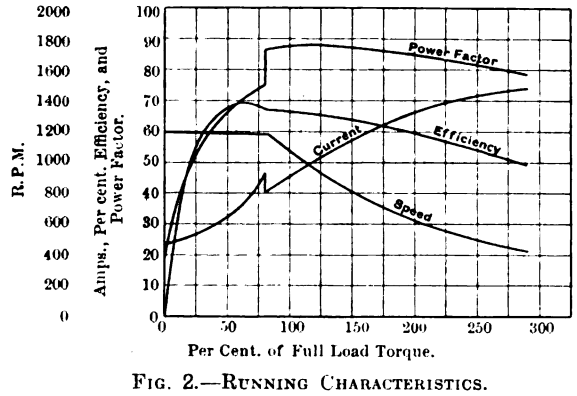

FIG. 2.—RUNNING CHARACTERISTICS.

torque of this motor is stated to be about 400 per cent. of the full-load torque, and is secured with about 200 per cent. of full-load current. Of course, in normal operation a motor will not be required to start on five times its rated load, as in general a lift making a five-second start will require less than 200 per cent. starting torque, even when fully loaded. In normal operation the current consumption indicated in Fig. 1 should be little, if at all, exceeded. The motor gives 120 per cent. of full-load starting torque with 130 per cent. of full-load current. In normal operation these motors seldom take more than 130 per cent. of full-load current; ordinary starts require less than 100 per cent. of full-load torque.

No auxiliary inductive devices, auto-transformers, slip rings, or other supplementary appliances are made use of in connection with this motor. A plain reversing rheostatic controller is connected up to the four terminals of the motor.

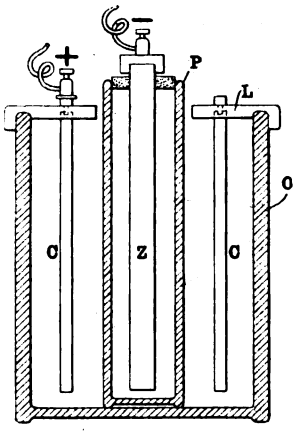
These motors for 60 cycles are also made for a normal operating speed of 810 and a synchronous speed of 900 r.p.m. The power factors are not quite as good as with the higher-speed motors; apart from this change, however, the slower-speed motors possess about the same advantageous characteristics as do the higher-speed machines.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN the *Chemical News* of August 28th James Strachan contributes some notes on "a new primary cell of the Daniell type." In the cell described the copper element is replaced by carbon, the copper sulphate by lead tetrachloride, and the dilute sulphuric acid surrounding the zinc by dilute hydrochloric acid or ammonium chloride. In the ordinary Daniell cell copper is plated out; in this cell lead; thus :—

Daniell cell ... ... $2H+CuSO_4=Cu+H_2SO_4$
New cell ... ... $4H+PbCl_4=Pb+4HCl$.

The form of the cell is illustrated in the figure below.



Within an outer stoneware jar *O*, a number of carbon rods (*C*) are placed, and these are electrically connected by the heavy leaden cover *L* to form the negative element. The rods may conveniently consist of stout arc-light carbons, the ends of which are coppered before the leaden cover is cast round them. A circular aperture in the centre of the lid admits the porous cell *P*, in which the positive element, an amalgamated zinc cylinder (*Z*) is placed. The carbon rods are surrounded with an acid solution of lead tetrachloride, and the zinc with dilute hydrochloric acid (1 : 7 water), or zinc chloride (5 to 10 per cent. solution), or ammonium chloride (15 to 20 per cent. solution); or a mixture of all these excitants may be employed.

Ammonium chloride	100 grm.
Zinc chloride	10 ,,
Hydrochloric acid	20 cc.
Water	to 1 litre.

The lead tetrachloride is prepared by dissolving 100 grm. lead acetate in 300 cc. water and adding 110 grm. of fresh bleaching powder, the mixture being contained in a strong pressure bottle. A vigorous reaction takes place, and when quite cold 700 cc. of strong hydrochloric acid are added, the bottle sealed at once, and cooled under running water. A solution of lead tetrachloride and calcium chloride is thus obtained, and this is directly employed in the cell. As a depolariser it is rapid, efficient, and constant in its action; and as long as any lead tetrachloride remains, polarisation cannot take place. In this respect it resembles the Daniell cell, but has a higher E.M.F. and a lower resistance. The chief disadvantage to lead tetrachloride is the powerful odour of chlorine which is evolved during its preparation and when charging up the cell. While the cell is in use the escape of chlorine fumes is prevented by the closely-fitting lead cover of the cell, the space between the inner edge and the porous foot being sealed, for the time being, with soft paraffin wax. After the cell has been in action for some time the carbon rods become coated with spongy lead, which is easily removed by gentle scraping. If the cell is required to give a large current output, the excitant should be strengthened by the addition of hydrochloric acid, the zinc should be heavily amalgamated, and the carbon rods replaced by carbon plates and surrounded with carbon granules. The E.M.F. of the cell with different solutions was found to be :—

	With zinc.	With iron.
Hydrochloric acid	1·41 ...	0·83
Zinc chloride	1·22 ...	0·75
Ammonium chloride	1·51 ...	0·95

With iron, as, of course, would be expected, the electromotive force is very much less.

Telephony in the Transvaal.—We learn from the *British South African Export Gazette* that a telephone line of over 210 miles in length is to be installed to connect up Pietersburg, Pretoria, and Johannesburg. It will be the longest telephone line in the Transvaal.

CATALOGUES AND PAMPHLETS RECEIVED

"EXCELLO" ARC LAMPS.—An attractive "folder" has been issued by the Union Electric Co., Ltd. Besides enfolding a pun and bearing a device on the outer page excellently contrived to attract attention, it contains various general remarks as to the economy, simplicity, and regularity of the firm's "Excello" flame arc lamp. The folder has been designed for the use of central station engineers, and a quantity of these will be supplied to them gratis, printed with their own name and address, on application to the firm.

COMBINED RAIL-JOINT AND ANCHOR.—A leaflet describing a new pattern of combined rail-joint and anchor has been sent us by Mr. R. Brown, of 16 Great George Street, S.W., from whom further particulars can be obtained. Both joint and anchor are made from an ordinary rail length by sawing off the

FIG. 1.—RAIL ENDS PREPARED FOR JOINTING.

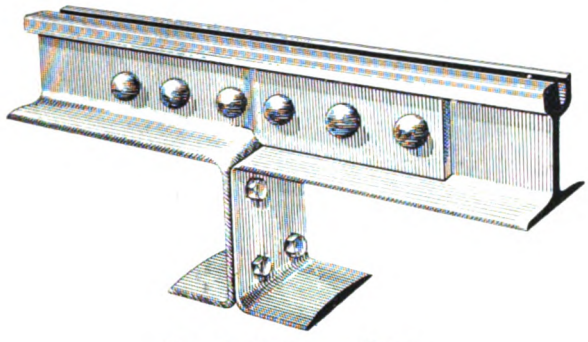

FIG. 2.—COMPLETE JOINT.

head of the rail for a certain distance, and also separating the web from the base. The base, bent downwards, forms the anchor, and the web takes the place of the usual fishplate. The method of making the joint is clearly seen in the illustrations above.

A CORD SHORTENER.—The Berlin firm of Classen & Co. (Barbarossastrasse 16) have sent us particulars of a simple arrangement they have placed on the market for shortening pendant cords to any desired extent. The annexed illustration practically speaks for itself. The material of which the device is made is wood, which is stained and polished. It is seen that the arrangement is such that there should be no possibility of the cord cutting.

CLASSEN CORD-SHORTENER. HALF SCALE.

ARC LAMPS, AUTO-TRANSFORMERS, AND AN AUTOMATIC TRANSFORMER SWITCH.—We have received from the Santoni Arc Lamp & Engineering Co., Ltd., a list containing particulars of their small auto-transformers for metal filament lamps, and also of an automatic transformer switch for switching out the transformer on no-load. The latter was described and illustrated in ELECTRICAL ENGINEERING, Vol. III., p. 440. The same list gives prices and particulars of the "Santoni" flame arc lamps, including the "Perl" enclosed lamp for 100 hours' burning. Reference is also made to the facilities at the Millwall works for executing re-winding of armatures and repairs of all descriptions.

CENTRAL STATION PUBLICATION.—We have received from the Borough Electrical Engineer of Grimsby a little pamphlet, entitled "Cheaper than Gas." This contains illustrations of shop windows lit by arc lamps, and various remarks as to the economy and efficiency of electric lighting. The pamphlet concludes with the statement that the Corporation sold 46 per cent. more electricity last year than in the previous year. An enclosed card extols the various advantages of electric lighting for private houses.

HEATING AND COOKING APPARATUS. A very complete catalogue has just been issued by the General Electric Co., Ltd. A large number of patterns of glow-lamp radiators are listed, together with a large selection of enclosed heaters, which are fitted with two or more heating elements, and an 8 c.p. lamp to show whether the current is on or off. The second portion of the catalogue contains particulars of kettles, saucepans, and other cooking apparatus. Nearly all these are fitted with a patent fusible cut-out, which prevents damage to the utensil if it is switched on without water in it, or allowed to boil dry. The fusible nut does not carry any current, but melts due to an increase of temperature and breaks contact by releasing a spring. The nut itself is composed of a special alloy. Full particulars of the current consumption of the various utensils are given. A novelty is an electric bread-toaster, which toasts both sides of the bread at once. This toaster can be obtained with two heating surfaces for toasting one large piece of bread at a time, or with several heating sections arranged one above the other. A single section one in the catalogue consumes 1,000 watts, and has two heating surfaces each measuring 8 in. by 10 in. To use the toaster the two surfaces are brought in contact by lowering the upper lid. The current is switched on to both portions for four minutes before toasting, and then the top is lifted, the bread inserted and pressed tightly between the sections. After about one and a half minutes the bread will be well toasted on both sides. Electric ovens, water-heaters, hot irons, cigar-lighters, curling-iron heaters, glue-pots, soldering irons, &c., are exhaustively dealt with.

"PIXIELITE" STRIP.—The General Electric Co. have chosen the opportune time of the approach of the Manchester Electrical Exhibition to call attention to their Pixielite lamp holder and strip for decoration and temporary lighting. Fig. 1 shows an Osram lamp in a holder on the strip, and Fig. 2 shows the underside of the holder before sealing, showing the connection and the method of securing the cable. The makers state that when the lamp-holder is connected and sealed it is absolutely water-tight, and that the insulation does not even drop when it is immersed in water. The holders take the ordinary B.C. lamp caps, and are suitable for either Osram or ordinary carbon lamp. As is seen in Fig. 2, the cable is secured to the holder independently of the terminals. The strip is kept in stock in lengths of 50 holders, spaced 12 ins. apart, with the lamps in parallel across the cables; and a special cable is also supplied which permits of the arrangement of the lamps in groups of either two or four in series, each group in parallel across the cable—a convenient arrangement with low voltage metal filament lamps. Any other arrangements are, however, made to order.

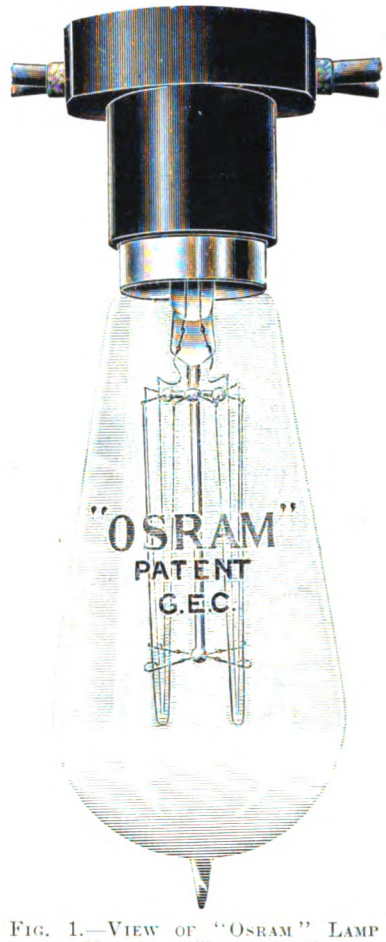

FIG. 1.—VIEW OF "OSRAM" LAMP IN HOLDER. (THE SAME HOLDER IS SUITABLE FOR CARBON LAMPS.)

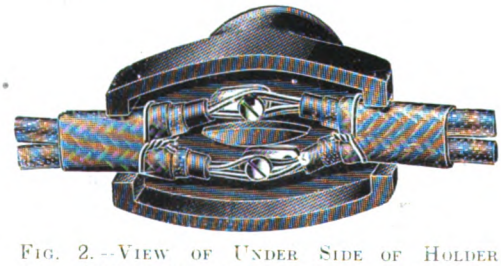

FIG. 2.—VIEW OF UNDER SIDE OF HOLDER (BEFORE SEALING), SHOWING CONNECTIONS AND METHOD OF SECURING THE CABLE.

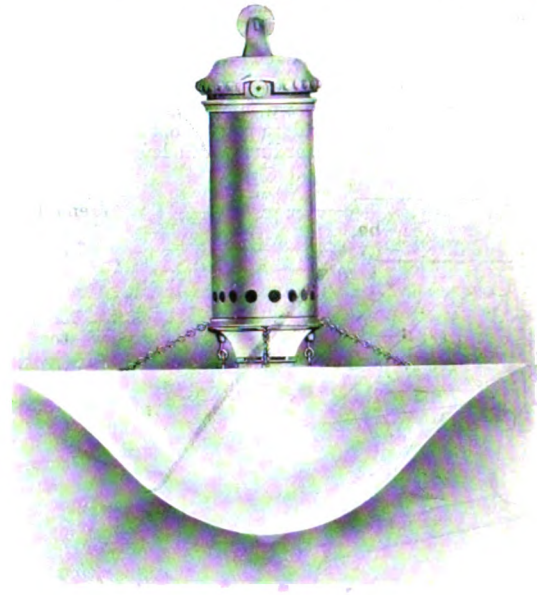
MINIATURE LAMPS.—A neat little catalogue of Howard candelabra and other minature lamps has been issued by Messrs. Neville, Williams & Co. A large number of candelabra lamps of various shapes, with candle-powers of from 2 to 16 are listed. Decorative lamps for series running, and metal and "metalised" filament battery lamps, for which consumptions of 1 and 1·5 watts per candle are claimed respectively, are included in the list. Some errors occur in the tables of current consumption of these lamps, but we have called the firm's attention to them, and they will be corrected in future issues. Surgical and telephone lamps of various shapes and sizes are listed and illustrated. A special multiple metalised filament lamp is supplied for automobiles and yachts, which is said to be much stronger mechanically than the tungsten lamp. This has four or eight straight filaments in parallel arranged as shown in the drawing, and is manufactured for pressures of from 4 to 12 volts, and candle-powers of 16 to 32. The consumption is given at 1·5 watts per candle. Two patterns of porcelain sockets for attaching lamps to "flex" for decorative purposes are also described.

HOWARD MULTIPLE FILAMENT LAMP FOR AUTOMOBILES.

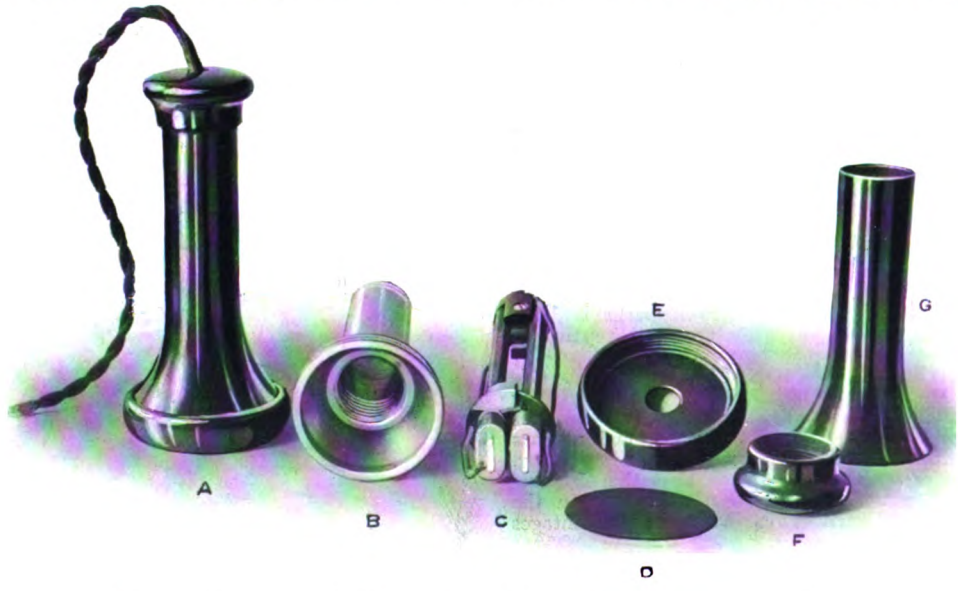
LOCKING LAMP-HOLDER.—A lamp-holder designed to prevent the withdrawal of lamps by unauthorised persons, made by the General Electric Co., is illustrated below. This is useful for large institutions or for cases in which the supply undertaker supplies lighting on a contract basis instead of by meter. The locking device works on the plunger of the holder, and is operated by means of an insulated key. The holder has already been found of special use in street lighting and other outdoor work where metal filament lamps are used, and it is deemed necessary to have an additional precaution against theft. The company's standard lamp-holder, with cord grip, and also their S1001, S1004, and S1006 patterns, with $\frac{3}{8}$ in., $\frac{1}{2}$ in., and $\frac{5}{8}$ in. thread, can be supplied, fitted with this locking device, at a small extra cost. A shade carrier specially made for these lamp-holders is also illustrated above.

LOCKING LAMPHOLDER. "ILEENE" SHADE CARRIER.

"JANDUS" ARC LAMPS.—A pamphlet from Drake & Gorham, Ltd., gives full particulars of the "Jandus" regenerative enclosed flame arc lamp, which was fully described in ELECTRICAL ENGINEERING, Vol. III., p. 299. This lamp is stated to burn for 70 hours with one pair of carbons, and with an efficiency of 0·22 watts per candle. Another new pamphlet from the same firm describes the various other patterns of arc lamps manufactured by the Jandus Arc Lamp & Electric Co., Ltd., which include single and double enclosed arcs, "midget" lamps, lamps for photographic purposes, and inverted lamps with opal glass reflectors, and clear glass cylinders. One of the latter is illustrated above.



TELEPHONE APPARATUS.—The British Insulated & Helsby Cables Co. have sent us a set of pamphlets on telephone apparatus, which are a model of excellent printing and illustrating. We reproduce one of the illustrations below, which depicts various parts of the Post Office pattern double-pole Bell receiver. The complete receiver *A* is seen on the left. *C* shows the permanent magnets and coils attached to a threaded metal collar, which screws into a metal sheath *B*; this holds them rigidly, and also adds additional strength to the receiver case. It is covered by the ebonite sheath *G*. The diaphragm *D* is placed at the end of the metal sheath *B*, and is clamped by the ebonite ear cap *E*, which screws on to *B*, and at the other end the cap *F* is screwed on, and this protects the terminals. The weight of the receiver is 13 ozs., a weight which ensures decided action on the switch-hook. A useful feature in the list is that the spare parts in the receiver are listed with prices, and are given code numbers. A breast-plate transmitter is also listed, which only weighs 4½ ozs. with its cord and band. A number of



BRITISH INSULATED & HELSBY POST OFFICE PATTERN TELEPHONE RECEIVER.

Digitized by Google

switchboards in various sizes are included in the set of catalogues, and there are very fine illustrations of the backs of some of these with the panels removed.

THERMO-COUPLES, PYROMETERS, AND TESTING INSTRUMENTS.—Messrs. Siemens Brothers & Co., Ltd., have just issued a supplement to their catalogue No. 502. This gives full information and prices of protecting tubes for thermo-electric pyrometers. The patterns include "Marquardt," quartz, and iron tubes, and a table, showing the type most suited to various kinds of high-temperature work, is given. Another pamphlet gives particulars of several patterns of pyrometers, including water, resistance, thermo-electric and optical pyrometers, and the necessary auxiliary apparatus. A third pamphlet describes several new types of electrical testing instruments, selected from the large catalogue previously mentioned in these columns.

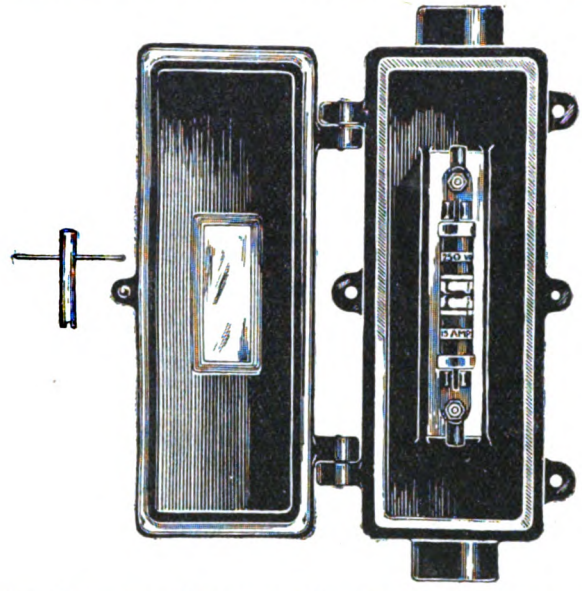
THE WITTON GRIP CONDUIT FITTINGS.—The Armorduct Manufacturing Co. have sent us a booklet containing a Faraday House report relating to their Witton Grip Conduit Fittings, and have also sent us a list of recent installations where this system has been employed.

ADVERTISING NOVELTIES.—Messrs. D. Harper & Co., of 258, 260, 262 Holloway Road, London, have sent us a catalogue of calendars, date cases, pocket books, diaries, &c., and draw attention to the desirability of making use of such methods of advertising in connection with the Manchester Electrical Exhibition.

PHOTOGRAPHIC ARC LAMPS.—A pamphlet is to hand from the Electrical Co., Ltd., in which are described various patterns of arc lamps for use in studios, and in engineers' and architects' drawing offices, for blue printing. Enclosed type lamps, with and without reflectors, and open type lamps with parabolic reflectors, are described. Tables showing the exposure required with the different lamps under varying conditions are given. Starters, adjusters, and carbons are also included in this pamphlet.

SEAMLESS METAL TUBING.—A catalogue received from W. Geipel & Co., describes their "Benedict-Nickel" seamless tubing. This tubing is made by a patent hot-rolling process, with white metal, and has the appearance of bright nickel. It is said to have a tensile strength of 50 per cent. higher than brass, and a very high resistance to bursting strain. The tubing is recommended for condenser tubes, plumbing work, railings, and many other purposes. It is said to be free from corrosion, and the electrolytic action met with in alloys. Tables giving weights, costs, and dimensions of the standard sections are given in the catalogue.

WATERTIGHT FUSE-BOX.—Simplex Conduits, Limited, have designed a new pattern of watertight house-service fuse-box, as shown in the accompanying illustration. It is of the usual form, but the addition of a lip on the cover and a circular india-rubber band allows of a watertight joint being made between the cover and the box itself. The most novel departure in connection with this is the arrangement for fastening, which



is done by means of a screwed key, by which the necessary pressure on the rubber band is obtained. The box is suitable for use with conduit up to 1 in. in diameter, either socket or screwed, and a small window is provided at the front for inspection purposes. Simplex standard enclosed fuses are used with this box. The price comes out at only a few pence more than that of the usual form of non-watertight box.

LOCAL NOTES

ABERDEEN: *Electricity Accounts.*—The annual report of Mr. J. A. Bell, City Electrical Engineer, for the year ended July 31st, states that 264 new consumers were connected during that period. Although no large works have been coupled up, the addition to the motor load is 316 h.p. Negotiations are practically completed with the Admiralty for a supply for wireless telegraphy at Stoneywood. On January 1st the department took over the Deeside and District Electricity Supply Co.'s undertaking, and since that time the supply for the Cults district has been continued from the steam station at Cults. The mains department has been exceptionally busy during the year, the conversion of the copper strip culverts to cables laid on the solid system having been completed in Union Street, Castle Street, and portions of Bridge Street, Market Street, Union Terrace, and King Street. Owing to the fall in the price of copper, these alterations have been carried out at a cost of £5,761, which has been taken from the reserve fund, the estimate being £7,917. The laying of extra high tension cables to Cults, it is expected, will be completed by the end of this month. The total number of units sold during the year for all purposes was 5,104,036, an increase of 309,529 over the preceding year. The output for private lighting was 69,395 units, and for power 181,352, in excess of last year. The cost of fuel rose to £8,376, an increase of £3,033, of which £2,270 is attributable to the increased price of coal.

Electricity Estimates.—The estimated revenue from the electricity department for the current year is £45,689, which is £2,000 in excess of the estimates for last year.

ASHTON: *Hospital Lighting.*—Although the new workhouse hospital has been wired for electric lighting, the Board of Guardians seem very chary of coming to a decision as to completing the installation. The Ashton Corporation, having borne the expense of laying a cable up to the workhouse walls, has made an offer to supply a minimum of 40,000 units per annum at 2d. per unit, but it is anticipated that the maximum demand will approximate 65,000 units. It is calculated that upon a minimum supply of 40,000 units there would be a difference of £107 in favour of gas, but the comparison, of course, does not end here. One member of the Guardians at the last meeting endeavoured to bring the matter to a head, but discussion of it has again been postponed.

AUSTRALIA: *New South Wales Tramway Finances.*—The report of the Chief Commissioner of Railways for the year ended June 30th shows that the length of tramways now open is 132¾ miles. The total capital expenditure during the year was £3,732,991, the revenue was £1,011,934, an increase of £103,293 over the previous year.

BARROW-IN-FURNESS: *Electricity Accounts.*—The report and accounts of the Corporation Electricity Department for the year ended March 31st, 1908, have been issued. The number of 8-c.p. lamps (or equivalent) now connected are 69,749 compared with 64,213 last year. Similarly, the number of motors has increased from 124, with an aggregate horse-power of 804, to 137, with an aggregate horse-power of 864. The number of consumers is now 724, against 668. The number of units sold was 1,047,776, against 948,747, an increase of 10·4 per cent. This is the largest increase in output since the acquisition of the tramway supply, and although it is principally due to the large motors connected towards the end of the last financial year, it is satisfactory to note that there has been an increase in the output for lighting in spite of the fact that a large number of consumers have reduced their consumption (in some cases as much as 40 per cent.) by the use of metal filament lamps. The accounts show that the capital expenditure on March 31st was £110,872. The total revenue was £12,428, compared with £11,798 for the previous year, and the total costs £6,440, compared with £5,360. The gross profit was therefore £5,988, against £6,437. After meeting interest on loans and sinking fund there is a deficit of £791, compared with a profit of £33 last year. The combined maximum demand from both traction and general supply was 892 kw., and the combined load factor 13·41 per cent., against 13·45 per cent. last year. The average price obtained for private supply was 3·25d., the figure for last year being 3·52d., and for public supply and traction 2·8d. against 2·9d. The works costs amounted to 1·094d., and the total costs to 1·474d. per unit. The figures for the previous year were 0·987d. and 1·356d. per unit respectively. The deficit of £971 is attributed to an increase of 25 per cent. in the price of coal, and an increase of £375 in capital charges upon plant, which is only partially employed.

BELFAST: *I.M.E.A. Expenses Surcharged.*—At the weekly meeting of the Tramways and Electrical Committee on Monday

Digitized by Google

the assistant accountant reported that the Local Government Board auditor had made several surcharges, those affecting the Committee being the subscriptions to the Municipal Electrical Association, and the expenses of delegates attending their conferences. The Finance Committee had appealed against those surcharges.

BIRMINGHAM: *Tram Track Experiments.*—The Birmingham Corporation have been experimenting with the new brake, which has been invented by Mr. A. W. Maley, late Assistant Engineer to the Leeds Corporation Tramways. This brake, which was described fully in ELECTRICAL ENGINEERING, Vol. II., p. 851, is a combination of the mechanical track and magnetic brakes. One reason that has induced the Birmingham Tramways Committee to experiment with new brakes is the accident upon the Warstone Lane route a short while ago. The experiments with the new brake were made upon the Garrison Lane gradient, which, although not the steepest in the city, has a fall of about 1 in 15. The Assistant Manager of the tramways, Mr. C. M. Hill, had charge of the car. One of the experiments was to allow the car to travel down the hill at over twenty miles an hour, but he was able to pull it up within fifty yards by means of the new brake. Rain was falling, and the track was wet and greasy, but no sand was used to assist the brakes. In another trial the car dashed down the hill at an estimated speed of about thirty miles an hour, and it was brought to an absolute standstill within eighty yards about halfway down the hill. The final experiment was to allow the car to run backwards, but it was safely brought to a stop. The results of the trials are to be reported to the Tramway Committee, and it is considered probable that the Maley brake will be adopted.

BOLTON: *Tramway Extension.*—Residents in the outlying village of Darcy Lever are petitioning the Corporation for a tramcar service in place of the motor-'bus which now serves the neighbourhood. The Tramways Committee fear the laying of lines to Darcy Lever would prove unremunerative.

BRADFORD: *Tramway Accounts.*—The annual report and statement of accounts of the Tramways Department to March 31st, 1908, have been issued. The total revenue from all sources is £243,148, an increase of £5,637 over the previous year. The car mileage was 5,331,007, an increase of 163,746. The number of passengers carried was 47,839,569, compared with 46,728,977. The total expenditure, excluding interest and sinking fund, was £167,994, and the gross profit of £75,154 is a net increase of £2,630. After meeting interest, repayment of mortgage loans, sinking fund, there is a balance of £17,238, which has been carried to the reserve and renewals accounts, which now stands at £52,229, after meeting this year's renewals. The profit last year was £145,364. Comment is made in the report upon the cost of electricity, and it is stated that if the Bradford Tramways Department could purchase electricity as cheaply as the neighbouring cities of Leeds and Sheffield, the power account would be about £15,000 less.

BRENTFORD: *Condition of Tramway Track.*—The District Council, at its first meeting after the summer vacation, again had under consideration the question of the state of the tramway track of the London United Tramways Co. A letter was submitted from Sir J. Clifton Robinson *apropos* of Col. Yorke's report on the recent Board of Trade inspection of the section of the tramways in the Brentford district, emphasising the assurance of the company's intention to carry out their obligations with all possible dispatch. The District Council agreed to a request from the Hampton Council to appoint representatives to a conference with regard to the state of the track.

BRIGHOUSE: *Electricity Supply.*—We mentioned last week that the Local Government Board had refused a loan in connection with a bulk supply from the Yorkshire Electric Power Co. We now give a few further particulars. The Corporation supply was started in 1898, being a continuous-current two-wire system at a voltage of 110. The development has, however, been on a very small scale, and the undertaking has proved an unprofitable one to the Corporation. In 1906 certain tramways were authorised by the West Riding Tramways Act under the provisions of which certain lines are to be constructed in Brighouse, and a supply therefore is to be taken from the Corporation. In view of this requirement, and with a desire to develop the existing supply for power as well as for lighting, the Brighouse Corporation entered into negotiations with the Yorkshire Electric Power Company for a bulk supply, and an agreement has been entered into. The Corporation proposes to alter their present system to three-wire 240-volt supply, and the general and tramway supply will be given from the sub-station situate in the centre of the town, the Power Company's supply being brought into the sub-station as three-phase current at 10,000 volts, and converted by means of rotary converters to direct current. The period of agreement is 14 years, and current is to be supplied on a sliding scale at £6 per kilowatt of maximum demand per annum, plus ¼d. per unit, with a guarantee that the maximum price shall not exceed 1·25 pence per unit. On this scale there is no doubt that the Corporation should be able to offer a power supply at very tempting rates, and in view of the very considerable importance industrially of Brighouse this is much to be desired. The sub-station will be provided by the Corporation, and the converting machinery by the Power Company, the distributing mains in Brighouse being the Corporation's. Messrs. Lacey, Sillar & Leigh are the consulting engineers to the Corporation. The step taken by Brighouse in shutting down their existing generating works is one for which there are several precedents, and it is a proceeding which will undoubtedly be followed by many other municipalities in districts where power companies are supplying. There are still a number of small municipal generating stations where the costs of production are so high that a cheap power supply cannot be offered to the ratepayers. Some of these are even now running at a loss, and unless very considerable further capital expenditure is made the only alternative open to them is to take a bulk supply.

BURNLEY: *Tramways.*—The Tramway Committee have considered recommendations by the promoters of the Blackburn, Whalley, and Padiham Light Railway asking for the approval of the Burnley Corporation of draft clauses to be inserted in an order to revive their powers. The draft clauses provided: (*a*) that Padiham Council might within six months from expiration of Corporation's lease of tramways in Padiham district give notice requiring the Light Railway Co. to sell to them that portion of company's undertaking within their district. The second clause related to working agreements with other councils or corporations. A letter was also read from the Padiham Council asking whether the Corporation would entertain a proposal to extend their present tramway from the terminus at Padiham to the top of Padiham, and, if so, whether the Corporation would receive a deputation from the Council on the subject. It was agreed to support the proposals of the light railway promoters, but the Corporation could not see their way to extend the tramway beyond the existing terminus at Padiham.

Watt Meters on Tramcars.—A proposal by the Tramways Committee to fix wattmeters on the tramcars in order to test the quantity of power used per car, has been referred back, after a long discussion.

BURSLEM: *Electricity Extensions.*—A deputation has been appointed to wait upon the Local Government Board, to urge the necessity of granting the Council powers to borrow £12,000 for the purpose of the electric lighting undertaking.

Noisy Tramcars.—A resolution has been carried by the Council requesting the Potteries Tramway Co. to effect an immediate improvement in the tramcars running in the town. It is stated that the jolting of the cars causes pictures to fall from the walls of houses along the route, and that the noise of the cars causes temporary cessation of work in schools.

CAMBORNE: *Mining Exhibition.*—A mining exhibition has been held here during the week, the whole of the arc lamps for the interior and exterior lighting of which have been supplied by the Union Electric Co., the lamps being of the "Excello" and "Koh-i-noor" types. The company has also a stand in the centre of the exhibition, upon which is a large motor-driven air compressor, and a direct-coupled triple-cylinder plunger pump, 3 ins. diameter, and 6 ins. stroke, delivering 735 gallons of water per hour. Owing, however, to want of space, and the short duration of the exhibition, this pump is not at work, but it will be transferred to the Manchester Exhibition, and there be actually at work as part of the company's exhibit. Other apparatus on the stand include a direct-coupled, electrically-driven centrifugal pump, alternating and direct-current motors, motor starters, measuring instruments, circuit breakers, safety fuses, &c.

DARWEN: *Electricity Charges.*—The Darwen Town Council have this week agreed to fix the following charges from October 1st to consumers of electricity for motors for the day-load only:—The first 500 units per quarter, 2d. per unit; the second 500 units per quarter, 1½d. per unit; above, 1d. per unit.

DOVER: *Electricity Extensions.*—The Engineer has reported that there are some 60 probable consumers in the St. Margarets district, representing 920 30 to 35 watt lamps. He also reports that there are several other probable consumers, representing some 200 lights, making a probable total of 1,120 lamps. Upon the basis of 1,500 lamps, he estimates that an expenditure of £3,000 will have to be incurred to supply the district.

DUNDEE: *Tramway Fares.*—The Tramway Manager has been instructed to prepare a report upon (1) a universal penny fare within the burgh boundary, starting at certain recognised points, and (2) a universal penny fare to passengers who may join the cars between any of these recognised starting points.

Tramway Accounts.—The annual report of the Tramway Committee for the past year shows that the gross receipts were £60,572, and the working expenses £39,879. Renewals absorb £4,000, and after allowing for interest, sinking fund, and depreciation, there is a surplus of £40, which is carried to reserve. The number of passengers carried have increased by 621,225, and the receipts by £2,900.

EASTBOURNE: *Electric Omnibuses.*—A suggestion that a service of electric omnibuses should be instituted has been rejected by the Watch Committee on the ground that the needs of the borough are sufficiently met by the existing service of municipal petrol omnibuses.

EAST STEYNING: *Electrical Charges.*—The question of the charges by the Brighton Corporation for electric supply is still

Digitized by Google

a subject for discussion between the respective Town Clerks. The matter has arisen through the decision of the Brighton Corporation a short time ago to abandon the maximum demand system of charging.

FARNHAM: *Electric Lighting.*—The Council is still unable to come to terms with the local electric light company with regard to the erection of overhead wires. It appears that the company has not been able to comply with a previous resolution of the Council with regard to placing the standards, wherever possible, at the backs of houses, in the plan which they have submitted. A resolution to the effect that the plan be rejected for this reason resulted in five votes for it and five against it, but the chairman gave his casting vote in favour of the resolution. Eventually a resolution was passed by six votes to three, referring the matter to the Public Works Committee, and asking them to specify in what way the plan does not comply with the conditions laid down by the Council.

FARNWORTH: *Electricity Accounts.*—There has been a loss of £322 on the past year's working of the electricity undertaking. The units generated number 973,086, of which 339,281 are for lighting and power for private consumption, 416,775 for traction and car shed, 55,930 for street lighting. The works cost per unit is 0·96, and the average price has been 1·16d. per unit.

FELIXSTOWE: *Proposed Purchase of Electricity Works.*—The Lighting Committee have presented a report dealing with the purchase of the works of the Suffolk Electricity Supply Co. The company have offered to accept £8,000, and the committee, after interviewing the Consulting Engineer, recommended that the only course open to the Council is to buy out the company on or before June 30th, 1909, and in the meantime to erect a steam generating plant. The company will be required to remove the four-cylinder gas engine and the producer set at their works, which has been the chief cause of the nuisances, and the buildings would afterwards be used as a sub-station. The Suffolk Electricity Supply Co. started as a private company in 1898 without a Provisional Order, but the Council obtained a Provisional Order in 1900. As, however, it was thought unlikely that sanction would be given to carrying on a competitive business, an agreement was entered into with the company, which was finally sealed on May 18th, 1903, for the purchase of their concern at £8,000, exclusive of the overhead mains. This agreement, however, the Board of Trade did not sanction, and it is now recommended that the company's offer of £8,000 be accepted on the conditions that the purchase includes the whole of the undertaking, with the exception of the gas engine and producer plant, that the transfer shall take place on June 30th, 1909, that all extensions in the meantime be made with the sanction of the Council, and that application be made to the Local Government Board and the Board of Trade for sanction to the proposal. After a good deal of discussion at the last meeting of the Council it was decided to bring the report up again at a special meeting on the 16th inst.

HASTINGS: *Trolley Omnibuses.*—A proposal that the Hastings Tramways Co. shall introduce a system of trolley omnibuses for the narrow streets of the town is to receive consideration.

Electricity Charges.—At the last meeting of the Corporation, Councillor Cox moved a resolution that the price of electrical energy to private consumers should be increased by 1d. per unit. After criticising the undertaking at some length, he stated that the amount now charged for energy was insufficient to cover the working costs After a long discussion the motion was defeated by 20 votes to 8.

HERNE BAY: *Provisional Order.*—The Council is to apply for an electric lighting Provisional Order.

LEEDS: *Tramway Receipts.*—During the twenty-two weeks of the present financial year, the total receipts upon the Corporation tramways have amounted to £148,571, an increase of £4,687 over the receipts for the corresponding period of last year.

LIVERPOOL: *Tramway Receipts.*—For the 35 weeks from January 1st to August 29th, the receipts of the tramways department amounted to £372,853, compared with £380,049 in the corresponding period of last year. The passengers carried have also decreased, the figures being 80,908,191 against 82,384,421. The chairman of the Finance and Traffic Sub-Committee has stated that the falling off in traffic has been general upon all the routes, and can only be attributed to the lamentable condition of trade.

LONDON: *Battersea: Tramways.*—The Borough Council has consented to the doubling and reconstruction of the tramway from Lavender Hill to Chelsea Bridge, the London County Council having agreed to pay £6,500 to the Council for releasing them from the obligation to pave and maintain any part of the roadway outside the track.

Islington: London and District Electricity Supply Bill.—A resolution has been passed by the Liberal and Radical Association recording that they view with profound alarm the London and District Electricity Supply Bill, as it will confer immense powers over a vast area, which could only result in the creation of a gigantic monopoly

Kensington: Conference Expenses Surcharged.—The Town Clerk is communicating with the Metropolitan Councils relative to the action of the District Auditor in taking exception to certain expenditure incurred by officials of the Kensington Council in attending technical conferences, explaining that whilst the Local Government Board had allowed the expenditure in pursuance of the Local Authorities (Expenses) Act, 1887, the Board had intimated that they will not undertake to sanction similar expenditure in the future. The Kensington Council considers that it is highly desirable that the Metropolitan Borough Councils should have the power to incur reasonable expenditure in respect of the attendance of members and officials at conferences having a bearing upon their duties, and a communication has been addressed to the London County Council asking them to insert in their next General Powers Bill a clause giving this power to the Borough Councils of the Metropolis. Co-operation is asked in the matter.

Shoreditch: Electricity Accounts.—The Electric Lighting Committee report that there is a gross profit upon the undertaking for the year ended March 31st, 1908, of £19,548, but after meeting capital charges there is a deficit of £236. It is pointed out, however, that the accounts are prepared on a slightly different basis to previous years. In accordance with a suggestion by the district auditor, the accrued proportions of interest and repayment, wages, &c., have been taken into account, and the additional amount thus cast upon the accounts for 1907-8 is £3,025; thus, but for this alteration, there would have been a surplus of £2,789. In addition, the committee state that the price of coal has been 21 per cent. higher than in previous years, whilst the income has increased by 8·52 per cent. The total expenses, including loan charges, have only increased by 3·57 per cent. The destructor accounts show a deficiency of £2,401 upon electricity revenue account.

MANCHESTER: *Trolley Omnibuses.*—It is understood that the deputation of the Manchester Tramways Committee which visited Germany to inquire into the working of the trolley omnibuses there, will advise the adoption of the system in certain suburbs of the city. The full report of the deputation, however, is now being prepared. The *Manchester Guardian* states that an official statement of the total expenses per car mile of a trackless tramline in one of the Rhine districts puts the management, legal, and clerical expenses at 0·561 pence; salaries, wages, and uniforms, 2·303 pence; power, 0·948 pence; renewal of rubber tyres (one pair of wheels), 0·658; other maintenance and repairs, 0·252; material, oil, light, tools, &c., 0·271; fire insurance, employers' liability assurance, contribution to road maintenance, sick and benefit funds, &c., 0·387; total cost, 5·38 pence. The working expense per car mile in Manchester last year was 7·07 pence, and thus a saving of nearly 2d. per car mile in this report appears possible under the trackless system. The cost of the power is largely in favour of the trackless system. The cost of power per car mile in Manchester is 2·02 pence; and while the cost of road maintenance will continue to be pretty much the same from year to year under the trackless system, it is pointed out that complete renewals of lines will, from time to time, be required in the case of the ordinary tramlines.

OLDBURY: *Transfer of Electric Lighting Provisional Order.*—The Electric Lighting Provisional Order obtained by the Council in 1900 has now been transferred to the Birmingham & Midland Tramways Co., the company paying the costs incurred by the Council in obtaining the order in addition to interest. The sum to be paid amounts to £536.

ONTARIO: *Electric Supply.*—It is stated that legal action is to be taken to restrain the Ontario Government from proceeding with the construction of the electric transmission line from Niagara. It is urged that as the Government has some £3,500,000 invested in the Canadian Electrical Investments Co. and the Toronto Electric Light Co., it cannot properly enter into competition with these private concerns.

PARAGUAY: *Telegraphs.*—A British Consular report states that during the year 1907 telegraphic communication has been established between Asuncion and Villa Encarnación. This line consists of 1,945 kiloms. (1,208 miles) of wire, at a cost of about 32,344 dol. (gold) (£6,469). A cable between the same town and Posadas, to which allusion has already been made, is shortly to be laid, and will thus connect Paraguay and Argentina by one single line. Telegraphic communication between the town of Villa Encarnación and Bella Vista on the Brazilian frontier is also in course of construction, and will, when completed, unite these two countries as well. A wire from the village of Yhú to the River Paraná, opposite the Yguazú Falls, is also contemplated.

PERTH (W.A.): *Tramway Receipts.*—The gross receipts of the Perth Electric Tramways Co., from January 1st to August 28th, amounted to £48,170, a decrease of £995 on the receipts for the corresponding period of 1907.

REDDITCH: *Electric Lighting Accounts.*—The report of the Electricity Supply Committee for the past year shows a loss of £509. It has been explained that the demand for energy for power purposes has decreased mainly on account of the removal of a large industrial concern to Birmingham, and exceptionally bad trade at other works. These losses and the increased cost of fuel, it is computed, represent a loss of over £800.

ROCHDALE: *Tramway Extensions.*—An agreement has been come to between the Corporation and the Whitworth District Council regarding the running of tramways in Whitworth. The lines, which will have a length of about three miles, will be constructed by the Rochdale Corporation, who will defray the cost, the Whitworth District Council applying for the Provisional Order.

SCOTLAND: *Telegraph System.*—The Post Office telegraph authorities are at present removing the telegraph poles and wires from the banks of the Union Canal, Glasgow, in consequence of the construction of the underground telegraph cable. A new arrangement has also been introduced into West Lothian and Stirlingshire districts. The poles have been transferred from the canal to the public highway, the telephone wires being above the telegraph wires. Between Edinburgh and Linlithgow the new underground cable is now in operation.

STOCKPORT: *Electricity Profits.*—The annual accounts of the Corporation for the year show that there has been a profit of £10,369 upon the tramways and £3,276 upon the electricity department.

SUNDERLAND: *Position of Electricity Undertaking.*—Alderman John Turnbull intends to bring forward a motion urging a complete independent valuation of the electricity works and the production of the detailed cost of power to each private consumer. The Alderman maintains that the electrical undertaking is in an unsound financial position.

WIGAN: *Electricity Charges.*—An offer by Messrs. Sharrock and Gaskell for a supply of electricity to their collieries at ½d. per unit has been accepted by the Electricity Committee. At the last meeting of the Corporation exception was taken to the acceptance of this offer on the grounds that it was unremunerative. An amendment that the matter be referred back to the Electricity Committee for further consideration was, however, rejected.

WOKING: *Telephonic Communication.*—Hitherto considerable delays have been experienced in telephonic communication between London and Woking, in consequence of the calls having to be made through Guildford, and some resentment has been felt at the anomalous position that whereas Woking is in the 3d. radius, the calls to London have been charged at 6d., because they have had to go *via* Guildford, which is in the 6d. area. Mr. F. J. Marnham, the member for the Chertsey Division of Surrey, which includes Woking, has taken the matter up with the Postmaster-General, and a petition signed by practically every subscriber to the telephone system has been presented. A communication has now been received from Mr. A. M. Ogilvie, on behalf of the Postmaster-General, stating that a direct line between Woking and London will be erected very shortly. It will not be possible, however, to reduce the fee until additional wires can be brought into use.

YORK: *Electricity Accounts.*—During July, 85,744 units were generated and 69,368 sold. The works costs for the month were 1·31d. per unit, against 1·06d. per unit for July last year, whilst the total costs, including less rates, &c., were 1·83d. per unit against 1·56d. per unit for the corresponding period of 1907.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ACCRINGTON.—The Local Government Board has sanctioned the borrowing of £7,500 for the purpose of the electricity undertaking.

CHELTENHAM.—A recommendation by the Electricity Committee for the expenditure of £700 upon new generating plant has been adopted. The new plant includes a condenser and motor-generator.

CLACTON.—The consulting engineer to the Corporation recommends the installation of a suction-gas plant at an estimated cost of £750, with a view to the more efficient and economical working of the electricity undertaking. It is also recommended that a travelling crane and meters be purchased at a cost of £265.

COLCHESTER.—A new high-tension cable is to be made from Barrack Street to Hythe Quay at a cost of £750.

DOVER.—Application is to be made to the Local Government Board for sanction to a loan of £3,000 for electricity extensions.

EGYPT.—Tenders are invited by the Minister of the Interior for the installation of an electrical works in the town of Zagazig. Tenders must be received at Cairo by October 29th, and a guarantee equal to 10 per cent. of the amount of the tender will be required.

HEANOR.—The Council has under consideration the question of erecting electricity works.

JOHANNESBURG.—Tenders will shortly be invited for 1,000 kw. steam turbo-generating set, which must be erected by December 15th.

PENDLEBURY.—We understand that Messrs. Andrews, Knolls & Sons, colliery proprietors, contemplate introducing electrical machinery at their various collieries at the Pendleton and Pendlebury districts, near Manchester.

PONTYPRIDD.—Tenders are invited for the supply and delivery of small house service paper-insulated cables, and small vulcanised rubber wires. Particulars from the Engineer to the Council, Mr. J. E. Teasdel, fee £1 1s., returnable, and tenders to the Clerk by September 21st.

Miscellaneous

BELGIUM.—The municipal authorities invite tenders for the electric lighting of the municipal "Salle de Fêtes, place de Meir." A deposit of 12,000 francs (£480) is required. Specifications may be seen at the Commercial Intelligence Branch of the Board of Trade.

BLACKBURN.—The Tramways Committee has decided to terminate the present contract for advertising rates on the tramcars. The chairman and vice-chairman of the Tramways Committee are to deal with the question.

GERMANY.—Tenders are invited by September 25th for eleven electric travelling cranes by the Finanzdeputation of the Hamburg Town Council. Specifications may be purchased for 15 marks at Schretanat II., Finanzdeputation, Hamburg, and tenders by the 25th inst.

HALIFAX.—The Town Council has sanctioned the construction of a loop line between Great Albion Street and North Parade, Waterhouse Street, to allow a through communication between Illingsworth and Skircoat Green.

MERSEY RAILWAY CO.—Tenders are invited for stores, including electrical sundries. Specimens may be inspected on the 14th and 15th inst., and tenders are to be sent in by September 18th. Particulars from the Secretary, Worcester House, Walbrook, London, E.C.

NORWAY.—An electric lighting installation is required at the Moss Station, Christiania. Tenders to Distriktsingeniorenskontor, Christiania, by September 19th.

SOUTH AFRICA.—It is stated that a telephone is to be erected between Pietersburg and Pretoria and Johannesburg, a distance of 210 miles, and that a telephone system is to be installed in Beira.

SPAIN.—The *Gaceta de Madrid* of August 26th contains a notice to the effect that D. Salvador Andreu, of Barcelona, has applied to the Direccion General de Obras Publicas, Madrid, for a concession for the construction of an electric tramway from the Plaza de Mosen Verdagner (Vallvidrera), following the Sarria-Vallvidrera road to the Torrente de Raventerola; other offers to compete with this may be made to the above-mentioned "Direccion" within one month from the date of publication of the present notice in the *Gaceta*.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations, and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Addition to premises in Roach Road, Poplar, for International Harvester Co., 80 Finsbury Pavement, E.C.

Public conveniences (£1,000), at Bow (electric light to be installed). Harley Heckford, Borough Surveyor, Town Hall, Poplar.

E.C.—Alterations (£1,000), Temple Church. Architect, Reginald Blomfield, 1 New Court, Temple, E.C.

N.E.—Twenty new warehouses and addition to existing warehouse, Morning Lane, Hackney. Architects, Hodson and Whitehead, 7 Finsbury Square, E.C.

Four houses, Upper Clapton. Architect, G. H. Paine, 62 Moorgate Street, E.C.

Workshop, Hackney. Builder, G. Keetch, 49 De Beauvoir Road, Hackney.

Six houses, Hackney. Builders, W. M. Dabbs & Son, 19a Gaulton Road, Lower Clapton, N.E.

Additions to factory, Homerton. Builder, G. S. Garey, 48a Old Street Hill, Clapton Common, N.E.

S.E.—Additions to Amersham Arms public-house, 388 New Cross Road, S.E. Proprietor, S. P. Janes.

S.W.—Offices for L. and N.W. Railway Co. Builders, H. and E. Lea, Camden Works, Great Church Lane, Hammersmith.

Alteration of premises, Victoria Street, for branch Williams Deacons' Bank. Builders, W. Cubitt & Co., 258 Gray's Inn Road, W.C.

W.—Buildings, Aldford Street, Mayfair. Builders, Foster & Dicksee, Rugby.

Digitized by Google

Alterations, residence, Curzon Street. Builders, Geo. Andrews & Co., 59 Craven Road, Lancaster Gate, W.

Alterations, residence, Grosvenor Street. Builders, Dove Bros., 15 Studd Street, Islington.

Stabling, &c., Reeves Mews. Builders, Maple & Co., Tottenham Court Road, W.

Alterations, Dundee Dye Works, Tottenham Court Road. Builders, Dove Bros., 15 Studd Street, Islington.

New clubhouse for Automobile Club on site of old War Office, Pall Mall. Architect, Purchase, 20 and 22 Maddox Street, W.

PROVINCES.

ABERYSTWYTH.—Hostel (£40,000). H. C. Fryer, Clerk Cardigan County Council.

BARNSTABLE.—Buildings in Charles Street. Builders, Cook and Sons, Bear Street, Barnstable.

BRISTOL.—Sunday schools (£3,000). Plans prepared by Rev. Canon Scales, Basingstoke.

BURSLEM.—Shops (£2,249). Architect, E. T. Watkin, Swan Chambers, Burslem.

CAMBRIDGE.—Extension of post office. H.M. Office of Works, Storey's Gate, S.W.

CARDIFF.—Additions, &c., to laundry (£550). Architect, H. Budgeon, 95 St. Mary Street, Cardiff.

COLNE.—Additions to Ball Grove Tannery. Builders, W. & J. Sagar, Park Road, Barnoldswick.

Two houses. Architects, G. Bower, 60 Market Street, Colne.

DARWEN.—School (£8,200). R. W. Smith-Saville, Surveyor, Town Council.

DUDLEY.—Additions to 116 and 118 Wolverhampton Street, for Davonport's City Brewery, Ltd.

Bakery in North Street for Dudley Co-operative Society.

Additions to schools. J. M. Wynne, Secretary Education Committee.

EALING.—School, Cranmere Avenue. Charles Jones, Borough Surveyor, Town Hall.

EASTBOURNE.—Alterations and additions to residence, Hampden Park. Architect, C. Wood, Whitley Road, Eastbourne.

Four houses, Brassey Avenue. Architects, Mitchell & Ford, 7 Gildredge Road, Eastbourne.

Alterations to "Red Lion" Inn for Southdown and East Grinstead Breweries, Ltd. (W. Bussey, Surveyor.)

Houses, Milton Road. Builders, L. P. Newman, 24 Ocklynge Road, Old Town, Eastbourne.

Houses. Architect, F. G. Cooke, 3 Hyde Gardens, Eastbourne.

Alterations, Sussex Hotel.

Addition to laundry. Architects, Mitchell & Ford, 7 Gildredge Road, Eastbourne.

Shops and flats. Architect, C. L. Morgan, King's Road, Haslemere, Surrey.

EBBW VALE.—Church, seating 500. Architect, G. E. Halliday, 14 High Street, Cardiff.

EXETER.—Extension (£9,000) of Hele's School. Secretary to the Governors.

HEBDEN BRIDGE.—Alterations, secondary school. Secretary to the Governors.

ILKESTON.—School (700 places). Architect not yet appointed. W. Lisset, Town Clerk.

KENDAL.—Fourteen houses. Architect, J. Banks, Kendal.

Infants' school. Architect, S. Shaw, 45 Highgate, Kendal.

LOWESTOFT.—Houses. Architect, W. J. Roberts, 124 London Road, Lowestoft.

Five houses. Architect, A. E. Clarke, Stanford Street, Lowestoft.

Painter's shop in Crown Street for Edward Chambers, Carriage Works, Crown Street, Lowestoft.

LUTON.—Carnegie Library (£10,000). Geo. Sell, Town Clerk.

MALTON (YORKS).—Grammar school. Architect, W. H. Brierley, York.

NEWCASTLE (Staffs.).—Wesleyan Sunday School (£800). Architect, R. T. Longden, 68 Moorland Street, Burslem, Staffs.

NETHERNE.—Isolation hospital and cottages in connection with Surrey County Asylum. Architect, Geo. T. Hine, 35 Parliament Street, Westminster.

NORBURY.—Shops and houses. Builders, Whitehead & Co., Clapham Road, S.W.

NORWICH.—Swimming bath (£2,860). E. A. Collins, Engineer, Town Council.

SOUTHPORT.—School (£11,214). F. W. Teague, Secretary, Education Committee.

SUTTON (Surrey).—Extension of premises for Wootton Bros., drapers. Builder, Wm. Salter, Webber Street, Lambeth.

WILLESDEN.—New railway station at Chapter Road. Architect, Matthew Garhutt, Bishop's Road Station, Paddington.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—The tender of Messrs. W. J. Campbell & Sons for the construction of twelve sets of wooden shutters at the generating station at £40 has been accepted.

BRISTOL.—The following tenders have been accepted :—Superstructure of Shirehampton sub-station, Messrs. T. Lovell and Sons, £419; switchgear at Avonmouth Dock, British Thomson-Houston Co., £177 5s.; two power-distribution boards at Avonmouth Dock, Messrs. Siemens Bros. Dynamo Works, £366.

BRITISH MANNESMANN TUBE CO. (SOUTH WALES).—Messrs. Willans & Robinson have received an order for a surface condensing plant.

BURNLEY.—It has been decided to extend the height of the chimney at the new electricity works by another 30 ft. at a cost of £264. The tender of Messrs. Mullins & Durkin for the boiler-house and chimney now amounts to £3,522.

The following tenders have been accepted :—Five car-bodies at £339 each, Messrs. Hurst, Nelson & Co.; electrical equipment for five cars at £262 10s. per car, British Thomson-Houston Co.; the trucks for the five cars are to be made in the shops of the tramways department at an estimated cost of £110 per car, and the accessories for the cars will be ordered at an estimated cost of £82 per car.

CORNWALL.—In consequence of the cost of wiring, &c., of the Asylum buildings having been estimated at about £3,000, it has been decided to accept the tender of the local gas company for the lighting of the building.

DEWSBURY.—A surface condensing plant is being supplied by Messrs. Willans & Robinson.

DUBLIN.—The following tenders have been received for the electric lighting of Sir Patrick Dunn's Hospital and Nursing Home :—Aston Bros. (accepted), £871; W. Coates & Son, £958; Barrett & Co., £997; Cummins & Co., £1,025; Maguire & Gatchell, £1,043; Egan & Tatlow, £1,172; Eaton & Davidson, £1,347. The tender of Messrs. Ferranti, Ltd., at £185, has been accepted for the supply of feeder panels at the Fleet Street station, and a tender by the same firm at £829 has also been accepted for a sub-station switchboard. The tender of the British Electric Transformer Co. has been accepted for the supply of a transformer plant at £1,698.

EDMUNDSONS ELECTRICITY CORPORATION.—An order has been placed with Messrs. Willans & Robinson for a surface condenser plant.

GUILDFORD.—Tenders have been received from the Guildford Electric Light Company and from the Guildford Gas Company for the lighting of the Upper High Street. The Electric Lighting company offered to do the work at £50 plus maintenance, whilst the Gas Company's estimate was £84 plus maintenance. The Electric Light Company undertake to erect 8 lamps of 15,000 c.p. each, and this offer was accepted subject to twenty tradesmen agreeing to share the cost of the scheme. It is stated that already eighteen signatures have been secured.

JAPAN.—Three sets of surface condensing plant are being shipped to Japan by Messrs. Willans & Robinson.

LONDON: *Battersea.*—Electric mains are to be extended (200 yards) at an estimated cost of £79 6s.

Hackney.—The Electric Lighting Committee has accepted the tender of Greenhill & Markham, 11 Great Sutton Street, E.C., at £346 16s. 8d., for painting and repairing work at the electricity and destructor works. In reference to the coal contract, the committee has reported that recently the Engineer rejected two barges of coal supplied by J. Hudson & Co., under their contract for the supply of 2,000 tons of Broomhill nutty slack coal at 12s. 3d. per ton. Hudson & Co. were then informed that the Council would have to buy against them as provided by the contract, and 110 tons of Cowdenbeath washed peas had to be purchased from Cory & Son, at 10s. 3d. per ton. Of the 2,000 tons of coal contracted for with Hudson & Co., 1,163½ tons have been received at the contract price of 12s. 3d. per ton, which, together with the 110 tons ordered against them from Cory & Son, leaves a balance of 726½ tons.

NELSON.—A tender for the supply of coal to the electricity works for the ensuing half-year from Mr. W. H. Shaw, of Haslingden, has been accepted.

WESTERN AUSTRALIA.—A surface condensing plant has been shipped by Messrs. Willans & Robinson.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—Messrs. Kennedy & Jenkin, the consulting engineers to the Westminster Electric Supply Corporation, have placed an order for five surface condenser plants with Messrs. Willans & Robinson.

COMPANIES' MEETINGS AND REPORTS

ABERDEEN SUBURBAN TRAMWAYS CO.—At the half-yearly meeting last week, the report and accounts, given in our issue for August 27th, were adopted. Mr. G. J. Walker, who presided, said that although the profit earned for the half-year to July 31st was greater than that earned during any corresponding half-year since they started, it was still not up to their desires. The profit for the half-year just ended was £835 10s., against £813 for the corresponding half-year of 1907. Last year, in consequence of the uncertainty with regard to their supply of energy from the Corporation, the directors considered it injudicious to pay a dividend, but since then the Corporation had agreed to refer the question of the price to be paid by the company at the termination of the existing agreement to a Board of Trade arbiter, and the directors were at present engaged in adjusting the exact terms of the agreement in reference to the arbiter. He was in hopes that this matter would be amicably adjusted very soon.

DUMBARTON BURGH & COUNTY TRAMWAYS CO.—At the first ordinary general meeting held in Edinburgh on Friday, the report and accounts given in our last issue were adopted. Major Charles Heaton Ellis, who presided, said that great credit was due to Messrs. J. G. White & Co., the contractors, for the expeditious manner in which the work had been carried out, enabling the company to benefit by the holiday and summer traffic this year. It was intended in a few weeks to make an issue of £80,000 five per cent. debentures, which would enable the company to discharge all its liabilities. The traffic receipts, he said, were continuing very satisfactorily, and he thought they had undoubtedly a valuable property.

DUNDEE, BROUGHTY & DISTRICT TRAMWAYS CO.—The report for the year ended July 31st shows a profit, including the sum brought forward, of £3,324. A final dividend is recommended upon the 6 per cent. preference shares, carrying forward £324. Before arriving at these figures, the directors of the statutory company have set aside £1,200 as depreciation, which fund now amounts to £2,500. The gross receipts from the tramways were £12,609. The meeting is on the 18th inst.

KENT COLLIERIES CO.—The report of the directors for the period of eleven months to May 31st, 1908, has been issued. It is stated that work on No. 3 pit was continued in the autumn of last year, but in view of the length of time that would be taken in remedying the defects in the electric pumping plant which had been supplied for this pit, and the great expense in running the plant owing to its inefficiency and its non-compliance with the guarantee given, it was decided to press forward operations by bringing Nos. 2 and 3 pits into communication. The report continues that between June 30th, 1907, and May 31st last there has been an expenditure in connection with the electrical plant of £1,227. The directors have reported from time to time as to the failure of the electrical plant installed in connection with No. 3 pit, and also as to the attitude taken by the electrical contractors in relation thereto. The Official Referee, before whom the case was heard, found that the electrical contractors had not supplied the machinery that they had contracted to supply, and that the guarantees as to steam consumption had not been complied with. From the legal point of view, the Official Referee measured the damages that he awarded to the company at £1,100, but, acting on the advice of counsel, the directors have decided to appeal against the amount of the award on the ground of its being insufficient, and being based on a mode of measuring damages not applicable to the case. (The action in question was reported at length in ELECTRICAL ENGINEERING, Vol. II., pp. 601, 684, 798, 987.)

LISBON ELECTRIC TRAMWAYS CO.—A meeting of the debenture holders was held in London on Thursday, at which a resolution was passed assenting to an alteration of the indenture securing the debenture holders. The resolution relieves the company of the restriction imposed under the terms of the trust deed of not being able to buy in the debentures of the company, and to re-issue them at any future time should this be to the interests of the company.

MANSFIELD & DISTRICT TRAMWAYS CO.—In issuing the accounts for the year ended December 31st, 1907, the directors state that the receipts so far this year show a substantial increase over the corresponding period of 1907, after meeting debenture interest to December 31st, 1907, and the interim dividend on the 6 per cent. cumulative preference shares to June 30th, 1907, the amount at the credit of revenue account is £2,688. The 6 per cent. cumulative preference shares for the half-year to December 31st, 1907, absorbed £1,800, and the remaining £888 carried forward. As the system was still under construction during part of the year, the directors have not dealt with the question of depreciation in the accounts, but intend to do so in future accounts.

MERSEY RAILWAY COMPANY.—The half yearly meeting was held in London on Wednesday last week, when the report and accounts were adopted. Mr. James Falconer, who presided, stated that there had been an increase during the past six months both in the receipts and in the number of passengers carried. The receipts for the year to June 30th were £102,811, whilst during the last half year of working with steam power, ended December 31st, 1907, the receipts amounted to £29,470 against £51,784 during the six months in review. In the same manner the number of passengers had risen from 3,357,000 to 6,867,000. With regard to the average receipt per passenger this had been reduced from 1·89d. in steam working to 1·67d. by electric working. He thought that these results showed in a very striking way the excellent service provided by the Company. The most hopeful feature of the undertaking was that the working expenses were practically stationary, so that as the receipts improved, the net profits were bound to increase to a much larger extent than would have been the case with steam working.

PUEBLA TRAMWAY, LIGHT & POWER CO.—The accounts for the half-year to December 31st, 1907, show a net profit of £7,463, after providing for bond interest, &c. From this surplus has been deducted certain preliminary expenses, leaving a surplus of £6,755, which it is proposed to carry forward.

SHEFFIELD UNITED GAS LIGHT CO.—At the half-yearly meeting on Monday, the Chairman referred to the fact that in May last the City Council decided to substitute electricity for gas in certain districts in the centre of the town, notwithstanding that the cost would be considerably increased. He maintained that the streets were sufficiently well lighted by gas, and the only reason for the change was apparently a desire to assist the electric light department at the expense of the rates. The Gas Company, being ratepayers, had every right to complain, especially in view of the fact that the electric light department only paid in rates for the year ended March 31st, 1907, £1,613, although their profits were given as £49,833. On the other hand, the Gas Company, whose profit was £89,768, paid no less than £18,251 in rates. Whilst it might be argued that the profits of the electric light department were subject to capital charges, the Gas Company's profits were also subject to the payment of dividends; thus the Gas Company paid more than eleven times as much in rates as the electric light department, although their profits were less than double. Therefore, the electric light department was either paying far less than they ought to, or the Gas Company a great deal too much. Carrying the comparison further, the Chairman stated that the combined water, tramways, and electric light department, with a total capital of over £4,000,000 and a profit in 1907 of £286,769, paid only £21,658 in rates against the £18,251 by the Gas Company, whose capital was only £970,355 and their profits £89,768.

YORKSHIRE ELECTRIC POWER CO.—The directors have pleasure in reporting progress during the half-year ending June 30th, 1908. During the half-year to June 30th the receipts from the sale of energy and for work done for consumers, &c., amounted to £8,698, against £7,293 13s. 5d. for the preceding half-year. The profit on the revenue account for the half-year amounts to £1,249, against £836 for the preceding half-year. After payment of mortgage interest the net revenue account shows a profit on the half-year of £363, as against a loss of £139 2s. 11d. for the half-year ending December 31st, 1907. This increase may be considered satisfactory in view of the general slackness of trade and the still prevailing high price of coal. At June 30th, 1908, agreements had been entered into with consumers for a total of 6,578 kilowatts (8,817 h.p.), being an increase of 1,030 kilowatts (1,380 h.p.) during the six months. Most of these agreements have been made during the latter part of the half-year, and the consumers are not yet connected. Amongst the new agreements is one with Electrical Distribution of Yorkshire, Ltd., for a supply of energy for tramway purposes in Ossett and Soothill Nether. New mains in the direction of Barnsley are being erected, and it is expected that a considerable load will be secured adjacent to the route. On July 9th, 1908, an extraordinary meeting of shareholders was held to sanction an issue of £45,000 of second mortgages on the undertaking of the company, for the purpose of providing the capital necessary to extend the company's operations, and £32,055 have been applied for and allotted. The directors have appointed Mr. Arthur Herbert Meysey-Thompson as a director to fill the vacancy caused through the retirement of Sir Richard Mottram. The meeting will be held at Leeds on the 29th inst.

Wireless Telegraphy in the West Indies and the Pacific.—A wireless telegraphy station has been established at the Swan Islands, Gulf of Honduras, and is in operation every day except Sunday. According to the *New York Herald*, the carrying out of a comprehensive scheme of wireless telegraphy connecting all the important islands in the middle of the Southern Pacific Ocean with Australia—a scheme which has long been contemplated—is now assured.

Accident at Messrs. Dick, Kerr & Co.'s Works.—On Friday last an inquest was held at Preston on the body of J. E. Johnson, an employee in the works of Messrs. Dick, Kerr & Co. According to the witnesses the man was working at a switchboard, and had hold of a switch handle, when he suddenly let go and exclaimed that he had had a shock. After walking a few yards, he fell unconscious. The pressure was only between 250 and 300 volts. A verdict of "Accidental death" was returned, but no explanation of how the man received the shock was forthcoming.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £63 10s. to £64 10s. (last week, £63 to £63 10s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A receiving order has been entered against G. H. Smith, electrical engineer, 15 Ashley Road, Altrincham.

Application was made to the Registrar of the London Bankruptcy Court on Tuesday by Mr. J. H. Callcott, Electrical Engineer, Clayton Works, Little East Place, Kennington, London, for approval to a scheme of arrangement whereby £28 per month should be set aside until a composition of 10s. in the £ has been paid. The statement of liabilities amounted to £1,953 and the assets to £5. The scheme was approved.

DISSOLUTION OF PARTNERSHIP.—J. P. Beckett and J H. Trolley, carrying on business as electrical engineers and contractors as J. P. Beckett & Co., at Victoria Street, Great Grimsby, has been dissolved. Debts by J. P. Beckett.

NEW PATENT ACT.—It is announced that the Stolz Electrophone Co., of Chicago, have decided to remove the foreign department of their works to London, in order to meet the requirements of the new Patent Act.

Street Lighting with Metal Filament Lamps.—A novel method of street lighting is being tried in a town in Michigan, U.S.A. According to the *Electrical World*, the installation consists of 15 spans across the street, with eighteen 60 c.p. 75-watt tungsten lamps in series on each span. The spans are 100 feet apart. The installation is said to be very successful from all points of view.

Electrification of Baden Railways.—The Berlin correspondent of the *Times* writes that according to the *Vossische Zeitung* the Paden Government has decided to introduce electric traction on the sections of the State Railway line between Basel and Zell, and between Schopfheim and Säckingen. The Siemens-Schuckert system will be adopted, and the electric energy will be generated at special stations, which are to be erected on the Rhine. The contract for the conversion of the line has been assigned to the firm of Siemens and Schuckert and to the Berlin Allgemeine Elektrizitätsgesellschaft. The new undertaking will be initiated with ten electric locomotives, each of which is, normally, to develop 1,000 horse-power.

Elastic Suspension for Metallic Filaments.—A recent issue of the *Electrical World* contains a description of a form of elastic suspension for the metallic filament of an incandescent lamp, for which a patent has been granted to Paul Druseidt, of Remscheid, Germany. A glass carrier for the filament spiders is supported at each end by spiral springs, and the leading-in wires are connected to the filament by the intermediary of a spring or similar flexible arrangement. Side supporting springs may also be used. It is stated that these springs have a cushioning effect upon the filaments and greatly lengthen the life of the lamp, particularly as they absorb vibrations and prevent friction and breakage of the filaments in their retaining elements or hooks. For this reason a larger number of retaining hooks than at present employed can be advantageously used.

Destruction of Wooden Poles by Birds.—The United States Bureau of Forestry reports that birds are destroying the telephone and telegraph poles in the South and South-west, particularly in Texas, Arizona, and California. In some places 50 per cent. of all the poles along the right-of-way have been riddled by these innocent offenders, which belong to the woodpecker family. One official reported having seen 25 telephone poles with 200 or 300 holes drilled clear through them. Some of the holes were 3 ins. or 4 ins. in diameter. Another counted the white cedar telephone poles along the right-of-way near Covington, Tenn., which had been affected by woodpeckers found that out of 268 poles, 110, or 41 per cent., had been bored. In some cases destruction of the pole takes only a few months, and the weakened condition makes it dangerous for a lineman to climb the pole. The real object of the birds in drilling the holes is uncertain. One telephone man stated that the humming of the wires was mistaken by the birds for insects excavating beneath the surface of the wood, and that they drilled the poles in quest of these imaginary insects. It is very probable, however, that the holes are excavated for an entirely different purpose. The woodpecker is a provident bird. At the proper season it stores up a supply of acorns and other foods for future consumption. In the summer these holes are often found stored with acorns. Many methods for preventing this damage have been suggested, but probably the most successful is preservation with creosote. A line of creosoted poles, opposite the one near Covington, was examined, and not a single hole was found. When it is considered that creosote will not only prevent the damage caused by the woodpecker, but also protect the pole indefinitely against both insects and decay, its great value as a preservative is apparent.

NEW COMPANIES

BAT METER CO.—This company was registered on August 27th, with a capital of £20,000 in £1 shares (12,000 preference), to carry on the business of manufacturers of and dealers in electric, gas, and water meters, &c. The subscribers are: P. Bertin, 23-5 Northdown Street, N., Civil Engineer; E. L. Biggs, 12 Montpelier Road, Holloway, N; J. E. Denney, 3 Great St. Helens, E.C., Chartered Accountant. Private company. The first directors (to number not less than three, nor more than seven) are G. Heely, 1 Waverley Place, St. John's Wood, N.W.; F. A. Brocq, 16 Boulevard de Vaugirard, Paris; and P. Bertin. Qualification, £100. Remuneration, £50 each per annum. Registered office, 3 Eden Street, Hampstead Road, N.W.

H. HOOPER & CO.—This company was registered on September 2nd, with a capital of £5,000 in £1 shares (3,000 6 per cent. cumulative preference), to acquire the business of an electrical engineer and contractor carried on by H. Hooper at 181 High Street, Lewisham, as "H. Hooper & Co." The subscribers are: J. W. Vincent, Chartered Accountant; J. B. Roberts, 49 Hurlingham Court, S.W. Private company. The number of directors is not to be less than two, nor more than five; the first are J. H. Bulkley and H. Hooper (permanent managing directors). Table "A" mainly applies. Registered office, 181 High Street, Lewisham.

INTER-URBAN ELECTRIC CO. (CANADA).—This company has been granted a concession to work electric railways and telephones and to supply electricity for heat, light, and power purposes in the municipalities of West Toronto and York. The capital is $400,000, divided into $40,000 shares of $10 each.

LETCHWORTH ELECTRIC SAW MILLS.—This company was registered on August 31st, with a capital of £1,000 in £1 shares, to acquire the business of a sawmill proprietor, joiner, and timber merchant, carried on by W. Jackson, at Works Road, Letchworth, as the "Electric Saw Mills." The subscribers are:—W. Jackson, H. Martin, F. Pearson. Private company. The number of directors is not to be less than two nor more than seven; the first are W. Jackson, H. Martin, and F. Pearson. Qualification, £50. Remuneration as fixed by the company. Registered office, Works Road, Letchworth.

MACDONALD, SYER & CO.—This company was registered on August 24th, with a capital of £1,000 in £1 shares, to carry on the business of consulting, civil, electrical, constructional, marine, hydraulic, agricultural, aëroplane, cycle, motor, locomotive, gas, tool, mining, textile, sewage, railway, inventors, and general engineers, &c. The subscribers are:—L. I. Woodley, C. S. Syer, J. W. Fletcher, W. E. L. Syer, S. W. Wilkins, J. G. Addinell, G. H. Addenbrooke. Private company. The number of directors is not to be less than two, nor more than five; the first are C. S. Syer (managing director) and J. W. Fletcher. Qualification, 10 shares. Remuneration as fixed by the company or by agreement. Registered offices, 41 Snow Hill, E.C.

ROSARIO & DISTRICT RAILWAY SYNDICATE.—This company was registered on August 21st, with a capital of £60,000 in £1 shares, with objects chiefly indicated by the title. The subscribers are:— J. H. Wilson, and E. J. Lyon. Private company. The first directors are to number not more than four; the subscribers are to appoint the first. Qualification, 250 shares. Remuneration, £150 per annum for the chairman, and £100 each for the others, with 3 per cent. of the profits available for distribution, divided (chairman to receive one-eighth per cent. of the said profits in addition to his share of the said 3 per cent.). Registered by Goddard & Co., St. Michael's House, St. Michael's Alley, Cornhill, E.C.

VICTORIA GARAGE & ELECTRICAL CO.—This company was registered on September 2nd, with a capital of £1,500 in £1 shares, to acquire the business carried on at St. John Street and Parkside, Coventry, as the Victoria Garage & Electrical Co., and the business carried on at 27 Fleet Street, Coventry, as the Stour Cycle & Motor Depôt. The subscribers are:—E. J. Swift, D. Thompson, A. Turner. Private company. The first directors are E. J. Swift (managing director), D. Thompson, and A. Turner. Registered Office, 68 John Street, Coventry.

New Transmission Lines from Niagara.—According to the *Electrical World*, the Hydro-Electric Power Commission of Ontario has let the contract for the erection of 293 miles of transmission lines. The lines will radiate from Niagara Falls in two directions—westward to St. Thomas, and eastward to Toronto. They are to be completed by December 1st, 1909. The towers, 3,176 in number, are to be 66 ft. high, 7,340 tons of steel being required for their construction. 1,014,209 lbs. of aluminium cable will be used. The contractor undertakes, upon due notice, not only to double the mileage at the contract rate, but also to furnish at the contract prices from 50 to 125 tons additional of aluminium cable for the construction of low-tension lines. This is to provide for any extensions that may be desired from municipalities on the high-tension lines to neighbouring towns and villages.

Digitized by Google

MISCELLANEOUS CITY NOTES

BRITISH INSULATED & HELSBY CABLES.—A dividend on the ordinary shares at the rate of 8 per cent. per annum, less tax, for the half-year ended June 30th is announced.

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. is declared upon the common stock for the quarter to September 30th, being at the rate of 7 per cent. per annum.

MEXICAN LIGHT & POWER CO.—A working arrangement has been come to between the Mexican Light & Power Co. and the Mexico Tramways Co., which will amount practically to an amalgamation. The *Stock Exchange Gazette* states that the Tramways Co. will become the dominating partner in the alliance, shareholders in the Light & Power Co. being guaranteed a minimum dividend of 4 per cent., with rights to further participation when the united earnings of the two undertakings exceed a certain figure.

RIO DE JANEIRO LIGHT, HEAT & POWER CO.—The *Financial News* states that the receipts of the Rio Janeiro Light & Power Co. for the thirty-third week of the year amounted to 693,999f., an increase of 42,664f. as compared with the corresponding period of the previous year. The gross receipts for the current year show an increase of 2,328,817f. The takings of the Rio Janeiro Tramways form about 50 per cent. of the total revenues of the Rio Janeiro Light & Power Co., and these receipts have fallen off considerably since the month of May, owing to the important electrification work, which has paralysed traffic on portions of the road. However, it is expected that towards the end of September some 25 kilometres of the line, situated in the heart of the city, where traffic is thickest, will be completely transformed for working by electricity and ready again for service, which the directors hope will soon make up the losses. Moreover, towards the end of the year 35 kilos. will be ready. Altogether within the next year the tramway system, of which 80 kilos. is now electrified, will have 250 kilos. running with electric power supplied by the company. The company is now working with five units of 8,700 h.p. each, and the sixth unit will be ready in a few days. The takings from this service are developing every day. While in May last the receipts from this part of the undertaking amounted to 242,000f., in June they had increased to 282,000f., and in July the figure reached 352,000f. The directors are quite sanguine that it will gradually reach about 1,000,000f. a month, when the whole plant has been installed, such is the demand for electric power in Rio Janeiro.

SAO PAULO TRAMWAY, LIGHT & POWER CO.—A quarterly dividend of 2¼ per cent. has been declared.

SOUTH METROPOLITAN ELECTRIC LIGHT AND POWER CO.—The register of the debenture stock holders, and transfer register, will be closed from September 17th to 30th inclusive, for the preparation of warrants for interest for the half-year ending September 30th, 1908, payable on October 1st.

The Venner Time Switch.—The Board of Trade have approved of the pattern and construction of the Venner time switch, type B, and of the mode of fixing it described in the specification and instructions sent out with the meter.

Submarine Signalling by Electric Bells.—According to the *Times*, the Submarine Signal Company have in hand the equipment for an electrical submarine bell for installation at Tarrifa. It will be worked by a dynamo in the lighthouse at Tarrifa, with a cable extending a quarter of a mile off the shore into 20 fathoms of water, the action of the hammer being controlled by electric magnets inside the bell casing. Similar electric bells which have been fitted on the Canadian coast have given entire satisfaction. The code of signals for the bell at Tarrifa is awaiting the approval of the Spanish Minister of Marine.

Telegraph Traffic.—At the present moment there are no less than eight cables waiting to be repaired; the latest interruption is that of the cable between Paramaribo and Cayenne, belonging to the French Cable Company.—The Las Palmas-Arecife cable has been down since May last, and those between Djedda and Souakim and Assab and Massowah since July.—The Kwardang-Merado connection was restored on the 8th inst., but the cable between Kotonou and Lagos is not yet working.—The cable between Cadiz and Teneriffe has also not yet been repaired. The scheme of the Spanish Government to lay another cable between these two points seems at present no nearer realisation.—The Colony of British Honduras is negotiating with the Mexican Government with a view of bettering telegraphic communication with the outside world. As yet this Colony is not joined to the Imperial telegraph system, although a cable between that Colony and Jamaica has long been discussed.

MUNICIPAL TRAMWAYS ASSOCIATION

THE programme of the annual meeting of the Municipal Tramways Association, which will be held in Nottingham on Wednesday, Thursday, and Friday, September 23rd, 24th, and 25th, has now been issued.

On Wednesday there will be a meeting of the Executive Committee at the Exchange Hall at 10 a.m., which will be followed by a reception by the Mayor, the Sheriff, and Chairman, and members of the Nottingham Tramways Committee, at 10.15 a.m. The Conference will commence in the Council Chamber of the Exchange Hall at 10.30 a.m., when Mr. J. Aldworth, the General Manager of the Nottingham Corporation Tramways, will deliver his Presidential Address. A Paper will then be read by Mr. H. E. Blain, General Manager of the West Ham Corporation Tramways Department, on "Some Through-Running Problems and Their Solutions." The Association will be entertained at luncheon at the Victoria Station Hotel by the Nottingham Tramways Committee, and at 3 p.m. there will be an inspection of the Trent Bridge car-repairing works and the St. Ann's Well Road generating station. There will be a reception in the Art Museum, Nottingham Castle, at 7.30 p.m., by the Mayor, Sheriff, Chairman and vice-chairman of the Tramways Committee.

The following Papers will be read on Thursday, September 24th :—(1) "The Treatment of Corporation Employees Incapable of Performing Ordinary Duty," by Mr. Alderman H. Linsley (Salford). (2) "The Application of Technical Science to the Construction, Maintenance, and Operation of Tramways," by Messrs. R. G. Cunliffe and J. G. Cunliffe (Manchester Corporation Tramways). (3) "Ticket Check," by Mr. L. Mackinnon (Glasgow Tramways). At 7 p.m. the Association Dinner will be held at the Victoria Station Hotel.

On the morning of Friday, September 25th, there will be a meeting of the Managers' section at 10 a.m., followed by the business meeting of the Association in the Council Chamber of the Exchange Hall at 10.30 a.m.

APPOINTMENTS AND PERSONAL NOTES

Mr. D. Campbell has been appointed Chief Superintendent of Telegraphs at Glasgow.

Mr. J. A. Hoffe, Chief of the Electric Signalling Branch of the Cape Government Railways, who recently retired on pension, has returned to England.

Councillor J. Smith, chairman of the Colne Electricity Committee, has been asked to accept the Mayoralty.

NEW PUBLICATIONS

"Science Abstracts." August. Section A. Physics: Section B. Electrical Engineering. (London: E. & F. N. Spon.) 1s. 6d. each.

"Cranes: Their Construction, Mechanical Equipment, and Working." By Anton Böttcher. Translated and Supplemented with English, American, and Continental Practice by A. Tolhausen. (London: Archibald Constable & Co.) 42s.

Institution of Mining Engineers.—It has been decided to transfer the headquarters of the Institution from Newcastle to London.

Proposed Memorial to Lord Kelvin in Belfast.—In connection with the project to erect a memorial in Belfast to Lord Kelvin, the meeting of the Executive Committee was held in the City Hall, Sir W. Crawford, J.P., being in the chair. Many members of the British Association were present, including Prof. S. Dill, Prof. J. Symington, Right Hon. T. Sinclair, Messrs. J. R. Fisher, R. T. Martin, and John Sinclair Apologies were received for non-attendance from several others interested in the movement, and it was reported that the sum of £1,852 has been received in subscriptions up to date A sub-committee, consisting of the Earl of Shaftesbury, Rev. President Hamilton, Sir Otto Jaffé, Right Hon. T. Sinclair, and Mr. R. T. Martin, was formed to arrange with an eminent sculptor with reference to the proposed statue, and to report to a subsequent meeting of the Executive Committee.

Hertford Light Railways.—The Board of Trade have confirmed an order made by the Light Railways Commissioners authorising the construction of light railways in the Urban District of Watford.

PRESSURE REGULATION ON THREE-WIRE SYSTEMS

AMONG the Patent Specifications published at the Patent Office on Thursday last is one numbered 15,846 of 1907, and granted to W. Fennell and W. P. Perry, relating to methods

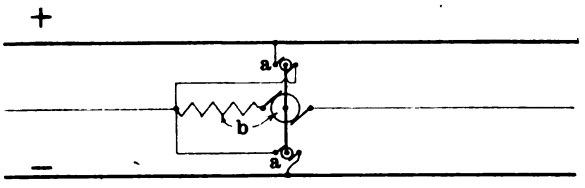

Fig. 1.

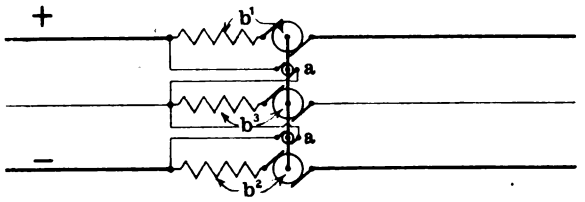

Fig. 2.

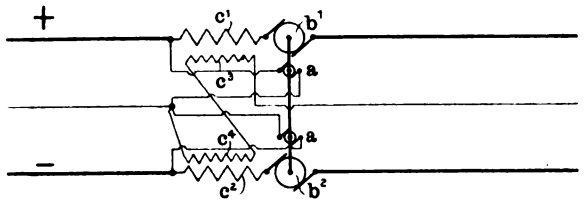

Fig. 3.

of regulating the pressure on three-wire systems. The method ordinarily employed in generating stations is to connect a balancer across the station bus-bars, but even if the fields are cross-connected, trouble is sometimes experienced in dealing with heavy out-of-balance currents, owing to the drop of pressure on the middle wire.

The present patent describes methods of connecting boosters, which are driven by the balancers, to compensate for this drop. The fields of these boosters are either connected in series with the middle wire, or with the outers. In the diagrams above the balancer fields are omitted for the sake of simplicity.

Fig. 1 is the simplest arrangement. In the neutral wire a series-wound booster is connected, mechanically driven by a balancer a, which raises or lowers the voltage of the middle wire bus-bar by an amount equal to the drop in voltage in the middle wire.

Fig. 2 shows a modified arrangement, with boosters, b^1 and b^2 in the outer feeders, as well as a booster b^3 on the neutral wire.

Fig. 3 illustrates another manner of achieving the same object without boosting the neutral wire, applicable when boosters are already applied to the positive and negative feeders. Additional coils, c^3 c^4, are placed on the boosters of the positive and negative wires. These coils are connected in series with the neutral wire; c^1 indicates the ordinary field coils of the booster b^1, and c^2 the field coils of the booster b^2. A fourth alternative is also suggested, in which the field coils c^1 and c^2 are omitted, for cases in which it is not desired to boost specially for drop of pressure in the outers.

It appears probable that these arrangements will compensate for larger out-of-balance currents, and also deal with rapid fluctuations of load more effectively than the ordinary balancer, but it is evident that it introduces an additional complication and expense.

Northampton Polytechnic Institute.—The recent provision of increased accommodation, obtained by the occupation of the British Horological Institute, not having been found sufficient for the growing requirements of this institute, an additional building is now being erected in the courtyard, and it is hoped that the greater part of it will be available immediately after Christmas. The new building will contain a lecture room larger than any of the existing lecture rooms, and also increased class-room accommodation. It also provides for the enlargement of the mechanical engineering workshops and the mechanical laboratory, and includes new power laboratories.—The prospectus of the Institute for the season 1908-9, which has just been issued, contains full particulars of the educational courses which can be taken at the Institute, and the various evening classes held there. There are day and evening courses in engineering (mechanical and electrical), in technical optics and artistic crafts, and in horology. In addition there are evening courses in technical chemistry and domestic economy. The classes of the day courses commence on Monday, October 5th, and those of the evening courses on Monday, September 28th. Enrolments for the latter commence on Monday, 14th inst. Full details of the syllabuses and the equipment are given in the prospectus. In the evening classes the electrical engineering department announces a full sessional course of lectures in wireless telegraphy and telephony, by Dr. J. Erskine Murray, the pioneer course held last May in this subject having proved to be very successful. There are also special advanced lectures on Heavy Electrical Engineering by Mr. H. M. Hobart.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 3rd, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

11,183. **Speed Control of Polyphase Motors for Marine Propulsion.** H. A. MAVOR, W. B. HIRD, and MAVOR & COULSON, LTD. A number of synchronous motors are mounted on a common shaft. The motors have different numbers of poles, but each motor is supplied with current from a separate generator at such a frequency that all rotate at the same speed. For example, four generators, having respectively frequencies of 20, 30, 40, and 60 cycles may be used with four motors mounted on a common shaft, and with 24, 16, 12, and 8 poles respectively. If these generators and motors are connected severally in the above order, all the motors will rotate at 300 r.p.m. This connection will be for normal speed and maximum power. If the 20 and 40-cycle generators are connected to the 24 and 12-pole motors respectively, a speed of 200 r.p.m. at half power will be obtained. By thus variously grouping the machines, speeds both above and below the normal full power speed can be produced. The system is suitable for land or marine propulsion. Three claims, four figures.

15,846. **Pressure Regulation on Three-wire Distribution Systems.** W. FENNELL and W. P. PERRY. The insertion of a booster, mechanically coupled to the balancer, in the neutral wire of a three-wire system, to compensate for the drop in the neutral. A short article on this arrangement, with figures, is given above.

18,165. **Automatic Telephone Exchange.** SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Improvements on that automatic telephone exchange system in which any given subscriber is selected by first setting one or more group selectors, according to the magnitude of the exchange, and then setting the selector which finds the individual subscriber. Each subscriber is provided with a preliminary selector, situated at the exchange, which is brought into operation by the subscriber by the act of lifting the receiver. This selector connects the subscriber with one of the group selectors. For operating the group selectors, the subscriber is provided with a current interrupter which enables him to break the circuit through his telephone instrument, and to earth either or both of the speaking lines. Should a called subscriber be engaged when the individual selector has been operated to make connection with him, a test line from his instrument will be found by the selector to be earthed, whereupon a releasing current will flow to return the selectors to their normal position. The present invention provides for circuits for locking the selectors when these have been operated by the subscriber; and further for disconnecting the speaking lines which have been connected by the selector operated by the calling subscriber, when the called subscriber is engaged. Twelve claims, two figures.

18,548. **Manufacture of the Active Plates of Alkaline Accumulators.** W. FENNELL and W. P. PERRY. The preparation of the active plates of an alkaline cell, having iron, nickel, cobalt, or copper as the active metal. The metal plate is alloyed to a certain depth below the surface, the proportion of the foreign metal gradually decreasing as the depth increases. The foreign

Digitized by Google

metal is then dissolved out, leaving a plate with a surface sufficiently molecularly porous to be formed up into peroxide. The unalloyed metal forms the support for the active portion. The alloying may be performed by heating the metal plate in contact with another metal in a finely powdered condition. Three claims, six figures.

18,582. **Protection of Alternating-Current Distribution Systems.** BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts Ges.*) A method of automatically isolating a section of a distribution system on the occurrence of a fault in that section. Reverse-current relays are connected to both ends of the section, and the contacts of these two relays are connected in series in an auxiliary circuit. The latter circuit comprises a single wire connecting the two relays, two auxiliary relays for operating the main section-isolating switches, and an earth return. When current is flowing in the section, one of the main relays is closed, and the other is open, and, as the contacts are in series, the auxiliary circuit is open. If the current for any reason flows in the opposite direction, both relays operate, one closing and one opening, and thus there is still an open auxiliary circuit. Should a fault occur in the section, current will flow from each end towards the fault, and consequently both relays will close, thereby completing the auxiliary circuit. The auxiliary relays will then operate, and open the section isolating switches. Four claims, five figures.

18,688. **Supports for Metal Filaments.** T. W. LOWDEN. A resilient support consisting of a spiral spring of glass, inserted between the lamp base and the supporting pillar, for the purpose of preventing the transmission of shock or vibration from the lamp body to the filament. Three claims, one figure.

20,867. **Commutation of Single-phase Motors.** ALLGEMEINE ELEKTRICITÄTS GES. In continuous-current interpole machines it is possible to omit half the number of interpoles, or all except two in the case of a simple wave-winding, but this is not practicable owing to the high self-induction of the short-circuited coils when in the zones without interpoles. According to the present invention, a certain number of the interpoles or auxiliary windings of a single-phase commutator motor are omitted, and the unneutralised rotor cross field which then exists in the commutation zone is utilised to induce an E.M.F. in the short-circuited coils to neutralise the short-circuit E.M.F. The auxiliary windings are either short-circuited through a regulating resistance, or are supplied with a potential proportional to the stator potential, and are arranged to be connected only at or about the synchronous speed. Six claims, two figures.

22,405. **Multiple Unit Control System.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). In multiple unit control systems in which the current for the controller circuit is derived from the main power circuit, the variations in the pressure of the system may interfere with the operation of the contactors, and render their action uncertain. According to the present invention, a resistance is inserted in series with the control circuit. A relay automatically short-circuits the resistance when the pressure drops below a certain value, and inserts it again when the pressure rises. Three claims, one figure.

22,481. **Speed Limiting Device for Series Motors.** ALLGEMEINE ELEKTRICITÄTS GES. The starting devices employed in connection with series motors subjected to widely varying loads have had to be designed so as to be available, either for starting the motor at full load, or at very light load; and consequently the resistance employed for starting the motor at low speed on light load had to be short-circuited when the motor was started under full load. In this way no means were provided for preventing the armature from speeding up after it had started. The present invention renders the safety of the motor independent of the operator, and provides for the automatic switching in of the series resistances corresponding to the different loads. The value of the series resistance is regulated by means of an electromagnetically operated switch, which is energised from the armature brushes, its operation being thus directly dependent on the speed of the armature. An auxiliary device for preventing the intermittent working of this controlling switch is provided. Four claims, four figures.

23,418. **Small Transformers for Metal Filament Lamps.** H. W. TURNER. The small "adapter" type of double winding transformer, which was fully described in ELECTRICAL ENGINEERING, Vol. III., p. 698. It is stated that enamelled wire is used for both windings; and the construction of the "turn-down" device is described. Three claims, seven figures.

24,589. **Arc Extinguishing Fuses.** F. POOLEY AND W. R. MACDONALD. Tubular fuses of the usual composition of lead, tin, and antimony, but containing a core of arc extinguishing or smothering mixture consisting of 60 per cent. bone ash, 30 per cent. carbonate of lime, 8 per cent. borax, and 2 per cent. charcoal. Two claims.

24,808. **Multiple Circuit Wave Winding for Single-Phase Commutator Motors.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) It has been usual to employ only one set of brushes of each polarity in alternating-current commutator motors, with multiple-circuit wave windings, as with a fractional winding pitch, and more than two sets of brushes, internal closed circuits consisting of as many coils as there are poles produced. These cause excessive heating and sparking. According to this invention a winding pitch exactly equal to the polar pitch is employed, and by this means short-circuiting of a number of coils together is avoided. The brushes of like polarity are connected together through portions of the compensating windings, which offer a high impedance to circulating currents. Three claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

14,059, GROB. System for electrically lighting and heating vehicles.
16,429, BURBEY & KERSLEY. Rails for tramways.
18,937, RYALL. Cases for thermal electric contact-making devices.
19,085, MARCONI'S WIRELESS TELEGRAPH CO. & MITCHELL. Tremblers for sparking apparatus.
19,174, BURLEIGH. Dynamo electric machines.
20,261, LUTZ. Make and break devices for magneto-ignition in internal-combustion engines.
20,491, HEYMANN. Electrode for secondary batteries.
21,017, SANDERS & DEAN. Apparatus for regulating the ignition in internal-combustion engines.
21,273, VANDERVELL & HOFFMAN. Magneto-electric machines for ignition purposes.
22,283, CÔTE & PIERRON. Electric furnace for the extraction of zinc from its ores.
22,523, MEEK. Magnetic separators.
22,736, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Air brake systems.
24,213, FELTEN & GUILLEAUME LAHMEYERWERKE ACT.-GES. Manufacture of steel.
24,217, CONSTANTINESCU. Single rail railways.
24,690, STIMSON. Burglar alarms.
24,852, SIDWELL. Brakes for tramcars.
26,055, HAGMÜLLER. Magnetic separation of iron particles from chaff.
27,375, GUENET. Tremblers for induction coils.
27,543, GIMINGHAM. Springs for use in filament lamps.
27,556, RÖCHLING & SCHOENAWA. Manufacture of steel.

1908 Patents

33, MAUNDER, THOMPSON, & MITCHELL. Tramway braking apparatus.
1,721, ALLEN. Railway and tramway points and switches.
2,127, MILLS (*Signal and Control Company*). Electrically operated whistles.
2,307, DE BOUILLANNE. Apparatus for sterilising water by ozone.
4,273, COWPER-COLES. Electrolytic manufacture of metallic foil.
4,274, O'KEENAN. Method of compensating friction of brushes in motor meters.
6,721, VEEVERS & BUTTERWORTH. Electric tramway points.
8,800, RACOT, RENAUD, & LANOÉ. Railway signalling apparatus.
9,502, ALLGEMEINE ELEKTRICITÄTS GES. Arc lamps.
10,211, POLLOCK & WERD. Insulators for telegraph wires.
11,511, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Electrical contacts.
12,265, KOCH. Transmitters for signalling systems.
12,678, GAGLIO & VILLANI. Cut-out.
13,088, SIEMENS BROS. & CO. (*Siemens & Halske Akt. Ges.*). Disc meters.
14,579, NICHOLSON. Electrically worked horn.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

8,277, SCHELLER. Production of high frequency oscillations.
9,789, DE SAINTE-CLAIRE. Variable-speed gear for electric automobiles.
14,513, TIMAR & VON DREGER. Motor starter.
14,825, SOC. ANON. MONTBARBON. High tension ignition apparatus.
16,900, TAYOUX, CHAUCHY, & FRAYSSE. Magneto electric machine.
16,986, SOC. ANON. WESTINGHOUSE & BRUN. Direct current electric motors.

Expiring Patents

The following patent expires during the current week, after a life of fourteen years.

17,529 of September 14th, 1894. **Telephonic Apparatus.** F. H. W. HIGGINS. A case of slate or other rigid non-metallic material for a telephone receiver, which will not respond to the vibrations of the diaphragm. Also a diaphragm, built up of two thicknesses of iron cemented together with shellac, and with a radial slit extending from the centre to the circumference. The bobbin of the receiver is wound in two parts in opposite directions. This specification also describes means for ventilating silent telephone closets by covered passages lined with velvet.

SUMMARY

The London premises of Messrs. W. H. Smith & Sons, the large newsagents and booksellers, afford an interesting example of the applications of electric lighting and of the electrical operation of printing machinery. We describe in this issue the lighting and power arrangements of the five large buildings in London, including the new one in Kingsway. The latter has an interesting automatic pumping plant. At the printing works in Fetter Lane there are about sixty motors, most of which drive printing machines. There are various types of starters and regulators in use; the automatic control of some of the larger machines is of particular interest. The lighting of the new building is entirely by tantalum lamps, of which also many are used in the old buildings. (Page 419.)

A new form of apparatus for obtaining the magnetisation curves of samples of iron by the ballistic galvanometer method has been designed by Prof. Gisbert Kapp. The two samples are connected by two short yoke-pieces with conically-bored holes to receive the ends of the sample rods. The errors due to the reluctance of the yoke and the joints are thus reduced to a minimum. (Page 420.)

An experiment in electric cooking is now being made at one of the Fleming's Restaurants in Oxford Street, and a careful record is being kept of the consumption of the various grills, hot-plates, and egg-poachers. We are able to give the figures for the first week's working, which are very favourable. Great satisfaction has been expressed with the results from all points of view. Current for the apparatus is obtained at power rates from the Marylebone Borough Council's mains. An improved form of grill is an interesting feature of the installation. (Page 421.)

In his report to the Victorian Railway Commissioners on the electrification of the suburban railways of Melbourne, Mr. Merz recommends a preliminary electrical equipment of some 29 route miles of track, which is considerably more than was originally proposed. An increase of 71 per cent. in the train-mileage, with an increase of only 23 per cent. in the ton-mileage, is expected. The system recommended is an 800-volt protected third-rail continuous-current system, with converter sub-stations supplied with three-phase alternating current from a steam turbine power station at Yarraville with a capacity of 35,000 electrical horse-power. (Page 422.)

Hitherto the water power in New Zealand has been the vested property of the State. A Bill is to be introduced in the New Zealand Parliament this session which will permit water power to be employed for private enterprise under certain restrictions. A correspondent reviews the situation, and emphasises the

Digitized by Google

opening for British electrical engineering firms. (Page 423.)

SOME particulars are given of the proposal of the Ontario Government to furnish electric power from Niagara Falls to the municipalities of that province within a radius of 150 miles. (Page 424.)

A DETERMINED attack on electric tramways was made by Mr. F. DOUGLAS FOX in a Paper read at the British Association meeting in Dublin. It was based on an analysis of 71 municipal tramways accounts, and its object was to show that there is a wide field for the electric trolley omnibus system with which he is connected. He gave the average total costs, including capital charges, of 71 municipal tramways as 9·96d. per car-mile, and the average revenue 10·52d. per car-mile. For the petrol 'bus the figure for total costs, including capital charges, was given as 11·7d. per car-mile; for the "Electrobus," 10·25d.; and for the trackless trolley car from 7d. to 9d. In the discussion very little attention was paid to these calculations, and no municipal tramway engineer or manager spoke. Mr. SHEARDOWN (Dublin United Tramways, Ltd.) suggested that the cost of the overhead line construction for tramways might conceivably be much reduced by using short brackets close to the poles and by developing the flexibility of the trolley arm. (Page 425.)

A PAPER by Messrs. J. BROWN and M. F. FITZGERALD described some experiments on rotating discs, to investigate whether certain approximate formulæ given in works on steam turbines were sufficiently accurate for practical purposes. The authors found that these formulæ cannot be trusted in every case for actual design. (Page 430.)

SIR JAMES DEWAR, F.R.S., has measured the amount of helium evolved from radium, and has obtained a figure agreeing very closely with Rutherford's theoretical value. Other Papers on electrical science and allied subjects read before the British Association were on the inductance of two parallel wires carrying alternating currents at high frequency, by Dr. J. W. NICHOLSON; on the measurement of large inductances containing iron, by Sir OLIVER LODGE and Mr. BENJAMIN DAVIES; "The Extension of Optical Ideas to General Electromagnetic Fields," by Dr. E. T. WHITTAKER, the Irish Astronomer Royal. A discussion on the inactive gases of the atmosphere was started by Sir WILLIAM RAMSAY, F.R.S. Mr. H. J. S. SAND described a process of rapid electro-analytical separation of metals. The much-debated subject of secondary radiation was further discussed. PROF. RUTHERFORD described determinations of the light on a scintillating zinc sulphide screen; suggestions were made as to the boiling point of radium emanation; measurements by Mr. H. H. POOLE of the rate of evolution of heat by pitchblende were recorded; and Mr. T. ROYDS described further experiments he had made on the constitution of the electric spark. Mr. L. C. BERNACCHI, who was with the *Discovery* Expedition, presented a report which contained his determination of the probable position of the South Pole. A report on the Falmouth Observatory readings was presented by the Committee. A Paper by Dr. GLAZEBROOK on the pentane photometric standard of the National Physical Laboratory entered into the question of the correction for the humidity of the air, and suggested that the standard humidity should be changed. Mr. COWPER-COLES contributed a Paper on the manufacture of metallic reflectors. (Pages 430–433.)

PARTICULARS are given of the recent strike upon the Sydney tramways, which was caused by the dismissal of a conductor. The strike, which only lasted three days, was brought to a close by the refusal of the railway employees to join the tramway men. A similar strike took place upon the Auckland (N.Z.) electric tramway system for a similar cause, but here the matter went to arbitration, which resulted in the reinstatement of the dismissed conductor. (Page 433.)

A PAPER dealing with the comparative value of electric and steam traction on main-line railways, was presented by M. PAVLITZKY to the Fourth Russian Electrotechnical Congress. The author considers that the ultimate limit to the economical capacity of a railway is prescribed by the power and other qualities of the locomotive, and that a general comparison between the peculiarities of steam and electric locomotives defines the character and extent of the improvements which are attainable by the substitution of electric for steam traction. The superiority of the electric locomotive over the steam locomotive as regards power and efficiency is dealt with at length in the Paper, and the conclusion is arrived at that a much smaller capital expenditure in locomotives is needed for a given traffic capacity on a new line when electric traction is adopted. The author finally points out that, where main lines are congested and worked beyond their economical capacity, electric traction promises improvement, financial as well as technical, sufficient to justify the capital expenditure. (Page 435.)

UNDER "Electrometallurgy and Electrochemistry" we give a brief report of the discussion upon the Ionic theory, opened by Prof. ARMSTRONG, and continued by Sir OLIVER LODGE and Sir WILLIAM RAMSAY, at the meeting of the British Association at Dublin. Two Papers were read at the same meeting on the rapid electro-deposition of metals for analytical purposes. An abstract of an article on the electro-deposition of nickel contains some valuable information with regard to the conditions necessary to obtain a reguline adherent and tough deposit of nickel. (Page 435.)

THE report of the Pacific Cable Board for the year to March 31st, 1908, shows a deficiency on the year's working of £77,544 18s., which has to be met by the several Governments associated in the enterprise. There has been a falling off in the gross traffic receipts of £2,852, whilst the expenditure has increased by £4,082. (Page 436.)

THE National Society of Telephone Employés has issued a statement to the effect that nearly a thousand of the National Telephone Co.'s employés have been dismissed during the past six months owing to a limitation in the new constructional work which the company has carried out, and that a discharge of from 5,000 to 6,000 men is anticipated between now and 1911. The Society has also stated that the company is refusing orders for telephones by the hundred, which, however, is contradicted by Mr. Franklin, the President of the National Telephone Co. We have endeavoured, without success, to ascertain from the National Society of Telephone Employés the number of men of each trade and from each district that have been discharged, but from information which we have received from them, it appears that a large proportion are occupied with overhead construction, for the Society is unable to suggest any other reason for the men not finding re-employment by the Post Office. The Post Office, however, assert that the number of dismissals is not more than usual at the end of construction work, the employment on which is always of an irregular nature, and that the Department is finding employment now for the temporary men who have been discharged. (Pages 437 and 446.)

AMONG the specifications published by the Patent Office on Thursday last is one by H. GROB for a train-lighting system, in which two storage batteries are employed; one of these is being charged while the other is assisting in exciting the dynamo and lighting the lamps. Different methods of obtaining the higher charging pressure are described. A specification by E. A. GIMINGHAM relates to the manufacture of quartz or glass tension springs for supporting metals filaments, and another by SIEMENS BROTHERS & Co. describes a

Digitized by Google

new form of platinum contact, for which only a small amount of platinum is necessary. A method of sterilising water by ozone is the subject of a patent by A. DE BOUILLANNE, and C. J. O'KEENAN has one for a device whereby the perturbations due to brush-friction in motor-meters are said to be eliminated. THE GRÖNDAL KJELLIN CO., LTD., have applied for the amendment of a specification relating to electric furnaces. A patent granted to THE PHONOPHORE CO., LTD., and E. W. SMITH for telephone calling apparatus and a switch-hook in connection with it expires during the current week. (Page 439.)

A SCHEME of competitive street lighting is now being carried out between the Bradford Electricity and Gas Departments.—After meeting all liabilities and a contribution to the rates, there is a balance of £978 upon the Chesterfield tramways undertaking for the year to March 31st, 1908.—A resolution has been carried by the Dublin Corporation, requesting the accountant to inquire into and report upon the general financial position of the electrical undertaking, regard being had to Mr. Hammond's original estimates, and to the salaries of all the employees.—The compensation claims in connection with the Pye Nest tramway accident at Halifax amount to £11,000 towards which the insurance Company will contribute £1,000.—The Hythe Town Council has refused to allow the National Electric Construction Co. to change the system of traction upon the tramways between Folkestone, Sandgate, and Hythe to overhead instead of the surface contact.—Upon the Kirkcaldy electricity undertaking there was a profit of £137 last year, and a net balance of £123 upon the tramways undertaking.—The Sheffield Corporation has voted the sum of £10,000 from the tramway funds for various relief works.—The Midland Electric Corporation for Power Distribution has notified the Wednesbury Council that it will not supply electricity in the district any further. There was threatened competition by the Council, who are erecting a separate generating station. —A recommendation by Mr. G. Wilkinson, the Electrical Engineer to the Harrogate Council, that a charge of 2s. 9d. per quarter per 30-watt lamp be made in the case of tenements, has been passed by the Council, but the Town Clerk has declared the proposed system of changing to be illegal. (Page 441.)

TENDERS may be looked for shortly in connection with Mr. Merz's scheme of converting the steam railways of Victoria to electric traction.—Local Government Board inquiries have been held at Burslem (£12,000), Bury (£72,000), Darwen (£4,300), and Wimbledon in connection with electricity extensions. The Neath Town Council is applying for a loan of £18,000 for electrical purposes. (Page 443.)

THE accounts of the United Electric Car Co., for the year to June 30th, show a profit of £12,187, including £5,095 brought forward from last year. After paying the preference dividends a balance of £6,187 is carried forward.—There is a net profit of £36,198 shown by the accounts of the Direct West India Cable Co. for the year ended June 30th.—The directors of the Newcastle and District Electric Co. have decided not to pay an interim dividend for the half-year just ended. A dividend of 4 per cent. per annum is announced upon the ordinary shares of the Bromley (Kent) Electric Light and Power Co. (Page 445.)

SOME curious papers have been read before the British Association, but that emanating from Mr. F. DOUGLAS FOX on "General Urban and Inter-Urban Transportation and Railless Electric Traction," stands almost by itself in its combination of features. It is nothing new that a Paper may have something of an advertising character about it, but the feature of Mr. Fox's advertisement for the goods of his company is a general vagueness as to their detail, cost, and working results, which would be remarkable in a prospectus. Figures he gives, in great abundance, but they are figures from the statistics of tramways—figures selected and treated with the object of showing that, on the whole, British tramways are commercial failures or socialistic devices for carrying the working-man at the partial cost of the ratepayers. This "crabbing" of the electric tramway was entirely gratuitous and superfluous for the purpose of describing "Railless Electric Traction." We have nothing to say against the electric trolley omnibus, *per se*, it is an interesting cross between the tramway car and the motor 'bus which may have a certain field of usefulness, but the very slow progress made by the system—eleven lines in seven years, according to Mr. Fox—suggests that its field is a rather circumscribed one. The question at issue as between the electric tramway and the electric railless system is, at bottom, a very simple one, viz.:—under what conditions does it pay to provide the most perfect road surface attainable for the purpose of reducing the working expenses of public service vehicles? A tramway is nothing more than an improved road surface, about eight inches wide for each track. The answer is very well known, and has been known in substance ever since horsed tramways came into competition with horsed omnibuses. The saving in working expenses is mainly under two heads: power expenditure and maintenance of vehicles. Against these have to be put the maintenance and renewals of the rails. If the balance leaves a sum sufficient to pay the capital charges on the track construction, the tramway is justified. The determining factor is the service to be provided for, and given a correct set of figures for the costs of construction and working in any particular case, it is not difficult to show that, for some particular frequency of service, the tramway will be the more economical undertaking. But there is a further point which Mr. Fox ignores, though he remarks upon the figures which illustrate it as "an anomaly." A tramway has a greater earning power, upon a similar route, than an omnibus service. The greater seating capacity of the tramcar enables it to take the passengers offering in the "rush hours" which the omnibus must leave behind, or must run extra car miles to carry. Tramway men know, by experience, that in most districts a route earns more money at 9d. or 10d. per car mile than at 1s. per car mile. The same thing would be true with a 'bus service, no doubt, but as the working expenses are higher, the 'bus cannot give so frequent a service as the tramcar remuneratively.

We have not analysed Mr. Fox's voluminous array of figures in detail, but certain inaccuracies in them, where we happen to have the correct figures at hand, inspire no great confidence in the bulk. For example, he states that the London tramway accounts show a deficiency of £25,000. No year is mentioned, but Mr. Fox will find that no payments from the rates have ever been necessary to balance the London tramway accounts, and that the "deficiencies" which have been talked about in various quarters are purely "paper" deficiencies. Again, he states that the average fare per passenger in London is not published. The last report published gives this figure as 1·04d. on the horse, and 1·06d. on

Digitized by Google

the electric lines. And the population of Maidstone is twice or thrice stated as 13,000, whereas it happens to be over 33,000. Another slight error that indicates that Mr. Fox's statistical conclusions may not be absolutely reliable is that he has included Belfast and Bexley in the sixteen Corporations having separate tramway stations for tramways and lighting, whereas both lines are supplied from combined stations. Passing on from inaccuracies of detail to broader questions, it is to be noted that Mr. Fox does not mention how he has treated the rates paid upon the tramway tracks. These are, in the ordinary course, reckoned as part of the working expenses, and we presume that Mr. Fox has included them, but they are, in effect, a special tax levied upon the tramway passengers, and upon no other users of the highway, so that, in discussing the finances of municipal tramways at least, credit must be given for these payments. Secondly, a large part of the expenditure on permanent way repairs is made in respect to the paving, which is not used or worn by the tramway traffic, and this is another contribution to the public funds from the tramway traffic, not levied upon other users of the highway, to be taken into account in any comprehensive analysis. Thus it is not true to say that the public travels partly at the expense of the ratepayer, but rather that the tramway passenger is specially taxed for the benefit of the ratepayer, and the benefit of other road-users. We are well aware that tramways, municipally and company owned, in this country are not so remunerative as they should be, considering the benefits they confer upon the public, but this is partly because the profits are misdirected, and not visible as such, although they exist. We shall welcome the electric trolley omnibus here, but we predict that its profitable field of action is through sparsely populated suburban and interurban districts, and that it will in many cases be only the pioneer of the electric tramway. We regret that its advocacy has been disfigured by Mr. Fox's very special pleading, which is likely to be utilised by the anti-tramway interests always with us.

MR. MERZ'S report to the Victorian Railway Commissioners on the electrification of the Melbourne suburban railways shows commendable confidence in the improved traffic results to be expected from the change. Mr. Merz's inside knowledge of the working of the electrified lines in the Newcastle district has, no doubt, assisted him in his forecast. The Melbourne lines are evidently working near the limits of their capacity with steam traction, and a large expenditure in new rolling stock, and doubtless in station and other accommodation, is immediately needed if steam is retained. In these circumstances it is not surprising that Mr. Merz recommends electrification. In the details of the scheme, so far as published, there is no great deviation from general "third rail" practice, excepting that the pressure of 800 volts is recommended, which is a considerable innovation in the direction advocated by Mr. HOBART and certain American engineers. The increase of pressure permits of material savings in the distribution system on the D. C. side, without going beyond reasonably safe stresses on the insulators and motor windings. The recommendations to generate all the power at a single station might have been anticipated from Mr. Merz, but the supply of 121 route miles from one station is a fairly bold proposal. Given this and third-rail distribution of direct current, sub-stations with rotary converters are necessarily part of the system. Mr. Merz no doubt considered the alternative of single-phase working with due care before deciding on the scheme recommended, and as his report appears to deal exclusively with the suburban lines, it may be supposed that the future possible electrification of the main lines, and the desirability of having a uniform system, has not been taken into account. Probably electrification of the main lines is a contingency too remote to justify any considerable sacrifice in the work which is immediately urgent. Details of the technical part of the report with maps of the lines would be very interesting, and we hope they will be made public in due course.

THE enthusiast who believes in the future of electric cooking will read with interest the short article which we publish this week on an application of it on an industrial scale in a London restaurant. It redounds to the credit of the Managing Director of Fleming's Restaurants and the Electrical Engineer to the Marylebone Borough Council that this experiment has been initiated, not merely as an advertisement, but as a true investigation as to the possible advantages and economies that may be arrived at with this means of cooking. So far, the results have been most encouraging, and further experience as to the durability of the apparatus, and the cost and the time lost in maintenance and repairs, will be awaited with interest. Hitherto, the most serious defect in the greater part of electric cooking apparatus, after its high first cost, has been the difficulty of executing what should be small repairs and renewals, and we trust that this matter is being given due attention by the manufacturers. It will be seen that one of the innovations described effectively removes the slur cast on electricity—and still applicable to gas cooking—that it was extremely difficult to grill a chop or steak perfectly by this means, and that the so-called toast would be more correctly described as roasted or stewed bread. The new grills for this purpose actually grill without burning, and they toast by heat which is radiated from a red surface, instead of being imparted by conduction from a dull one. The thoroughly practical nature of the experiment is indicated by the figures of energy consumption obtained from separate meters connected to the various appliances.

The New Garage of the Electric Landaulet Co.—A new garage for electric automobiles has been opened recently by the Electric Landaulet Co., Ltd., to supplement their large garage at Chelsea. There is accommodation in the new garage for about 25 electric cars, and a special shed is reserved for petrol cars. It is very conveniently situated in Salisbury Mews, opposite the Great Central Hotel, Marylebone. Power is taken from the mains of the Marylebone Borough Council, and as the supply is continuous current, the cells are charged direct without the intervention of any converting plant. The difficulty of the high voltage is surmounted as follows:—The three-core concentric service cable, with 480 volts across the outers, is brought in to the main board, and the supply is there divided into two 240-volt circuits. Each of these circuits consists of five pairs of panels, each pair consisting of two 120-volt panels connected in series. There is a meter, a demand indicator, a double-pole fuse, and a double-pole switch for each of these 240-volt circuits. Each panel contains an ammeter, fuse, and series resistance. As there are twenty panels altogether, 20 cars can be charged simultaneously, but as it is often necessary to charge one only, a few spare batteries are always connected up, and one of these can be charged with the single car. If a car is needed in a hurry, one of these spare batteries is substituted for the spent battery, and a hand-trolley is provided for this purpose.

ELECTRIC LIGHT AND POWER AT THE PREMISES OF MESSRS. W. H. SMITH & SONS

THE London premises of Messrs. W. H. Smith & Sons, the large stationers and booksellers, comprise no less than five large buildings and many small branch shops, and there is, besides, the binding-works at Letchworth. In the present article we intend to describe the lighting and power arrangements at the four London buildings, in particular at the new building at Kingsway, which is devoted to the stationery and advertising departments, and at the printing works in Fetter Lane. In order to avoid confusion, it will be best to deal with each building separately.

Kingsway Building.

Lighting Arrangements.—The Kingsway building is quite new, and is devoted to the stationery and advertising departments. Current is obtained from the service mains at a pressure of 2 × 100 volts three wire and the lighting is carried out almost entirely with tantalum lamps, of which there are about 500, some 100-volt and some 50-volt lamps. The wiring is done in wood casing in the ground and upper floors; particular care has been taken to harmonise this casing with the general decoration of the rooms in the case of the ground floor, which is used as a shop. In the basement the wiring is in exposed iron conduit. The service cables are brought in to a switchboard with separate lighting and power panels, and the cables from this board to the distributing boards, lift, and other motors, &c., are carried in iron troughing suspended by iron brackets from the ceiling. This troughing, which is self-fastening, was supplied by Messrs. Gibbons Bros., Ltd., of Dudley. The method by which the sections of troughing are joined together can be seen from Fig. 1. The distributing boards on the various floors are worthy of notice. These have the usual hinged glass fronts, but the box itself is also hinged to the supporting board on the wall. This renders the back connections easily accessible, as there is a space between the box and the board for the coiled-up ends of the cables. Besides the fuses there is a switch on each pole of each circuit; the whole set of switches in the box are mechanically connected, and are operated by a handle outside the box. These boxes were supplied by the Edison & Swan United Electric Light Co., Ltd. There is an "intercommunication" telephone system with 25 stations. This latter and also the whole of the lighting work was installed by Messrs. Tyler & Freeman.

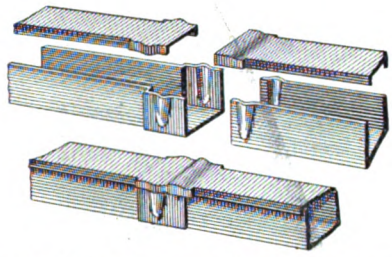

Fig. 1.—Self-Fastening Cable Trouching.

Power.—The application of electric power is represented by two lifts, one passenger and one goods lift, an electric winch for hoisting fodder to the upper floors and the three-floor stables adjacent to the Kingsway building, and the pumping plant which is described in a separate section below. Both the lifts are Pen-

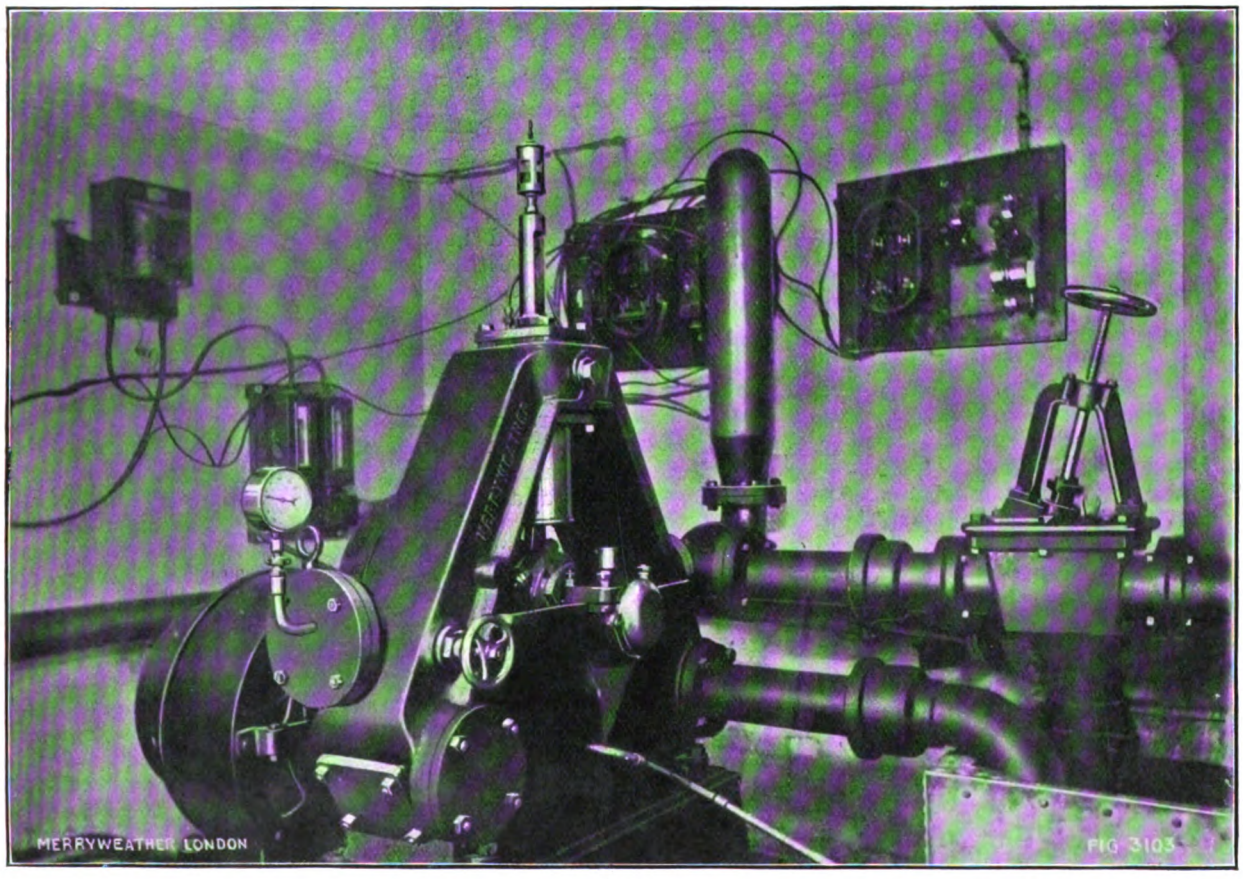

Fig. 2.—Merryweather Pump, Motor, Automatic Switchgear, Supply Tank, and Fire Main.

Digitized by Google

rose lifts, the goods lift being provided with switch-button control. The winch is driven by a Rhodes motor.

Water Supply.—The building is nine floors high, and the tanks for the general water supply are situated in special rooms on the roof about 110 ft. from the ground. As the street pressure would only suffice to give a supply to the fifth floor, a system of automatic pumping has been installed by Messrs. Merryweather & Sons for the water service to the floors above and for the fire service. It was required that the apparatus should ensure a constant supply of water for domestic purposes and for the heating apparatus without the use of steam or other machinery requiring labour for its working and control, and it was also necessary that powerful jets for fire extinction should be available on every floor and on the roof. The system includes a powerful "Hatfield" pump driven by an electric motor, arranged to draw water from a tank in the basement supplied through an equilibrium valve, and delivering into a fire main carried to a 500-gallon tank in the roof. A branch is also fitted to supply another tank of the same capacity for domestic services and the hot water system for heating the building. Hydrants, hose, &c., are placed on each floor, and, in the event of a fire, any hydrant opened would be first supplied from the roof tank. Over this tank is a smaller tank containing a float connected to a switch, and as soon as the water level falls in this smaller tank the main current is switched on automatically, and the pump starts running to maintain the supply. The pump cannot supply the tank except through a relief valve set to open under a pressure more than sufficient to throw a jet over the roof, water from the fire main being prevented from entering the bottom of the tank by a reflux valve. While any hydrant is in use the pump continues working, and as soon as all hydrants are shut off, the pressure in the main continues to rise until the top relief valve opens, fills up the tanks, and the current is switched off by the action of the float before referred to. The supply to the domestic tank is controlled automatically in the same manner, with the exception that the switch does not come into action until the water level has fallen to within 12 in. of the bottom. Then the pump starts and runs until the tank is filled up again. This arrangement prevents the continual stopping and starting of the pump which would otherwise occur all day long.

A general view of this pumping installation is given in Fig. 2. The motor, which drives the pump through reduction gearing, can be seen on the left of the photograph. The meters are also on the left, and the two relay switches for the fire and domestic service tanks respectively are visible at the back. It will be noticed that the photograph was taken before the wiring was permanently fixed. This plant has been examined and approved of by fire and other authorities, and illustrates a way in which the high buildings which are springing up in all our large cities may be protected from fire without calling for expensive alterations in the water supply arrangements.

Printing Works: Fetter Lane.

Lighting Arrangements.—Current for lighting and power is obtained from the mains of the Charing Cross, West End & City Electric Supply Co., at 2 × 200 volts, three wire. There are two service cables from different sections of the distributing network, and a change-over switch is on the main switchboard. The board is divided up into power and lighting panels, and the back of the board is easily accessible. The cables to both power and lighting circuits are in iron tubing. There are in all about 500 lamps, most of which are carbon filament. Mann, Egerton & Co., Ltd., of Norwich, were the contractors for this installation, and also for the power installations described below.

Power.—All motors, with the exception of those below 3 h.p., are connected across the outers of the 400-volt supply system. Some two or three years ago all the machines in these works were driven from shafting by gas-engines, but now all are driven electrically, and, with a few exceptions, the shafting has been removed. There are about sixty motors in all; these range from 7 to 1 h.p. in capacity. Most of these drive printing machines, but there are a large number of cutting, folding, and stitching machines. Many of the machines are driven from shafting suspended from the ceiling or run along the floor under platforms; for instance, three cutting machines are driven by a single 5 h.p. motor. All these machines are provided with heavy flywheels. The large lithographic printing machines are belt-driven by separate motors; the motors in some cases are suspended from the ceiling of the floor below, the belting being carried through the floor. In the setting room there are six linotype machines in two groups of three; each group is driven by a single 1-h.p. motor. Various methods of starting and controlling the motors are in use.

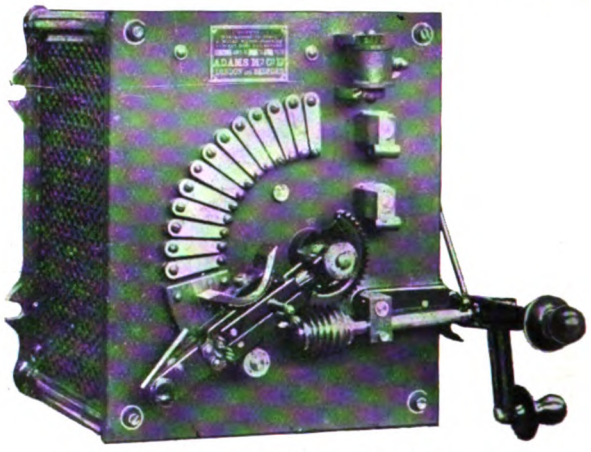

FIG. 3.—STARTER WITH WORM AND WHEEL GEAR.

The simplest of these is that in which a hand starter, as illustrated in Fig. 3, is used. This is an ordinary starter with no means for regulating the speed, but the method of preventing an operator from switching over too quickly is interesting. A handle (which is outside the cover) operates the worm and wheel gear; the worm does not normally engage the wheel, but is made to do so by depressing the lever shown in the illustration. This leaves the switch-arm free to fly back when the no-voltage release operates. Some of the machines require a certain amount of speed regulation, and these are fitted with special compound controllers. These control the speed between normal speed and 50 per cent. of normal speed by inserting resistance in the armature circuit, and between normal speed and 25 per cent. above normal by inserting resistance in the shunt field circuit. To enable the switch-arm to be left in any position, and at the same time to fly back to the off-position on the operation of the no-voltage release, the following device is fitted:—The armature of the no-voltage release holds a pin up into a notch at the base of the switch-arm; for every position of the arm there is a notch, and so long as the armature is held down, the arm is fixed. Should the armature be released, however, the pin leaves the notch, and the arm flies back. The field resistance contacts are reached by the switch-arm only after all the series resistance is cut out, and it is impossible to start the motor with a weak field as when a separate field regulator is used.

A large number of the printing machines are provided with automatic control apparatus. This con-

Digitized by Google

sists of an automatic self-starter, a solenoid main switch, and a tumbler switch on the machine itself. For motors of less than 3 h.p. the solenoid main switch is not required, however. The working of this automatic control is as follows:—The tumbler switch on

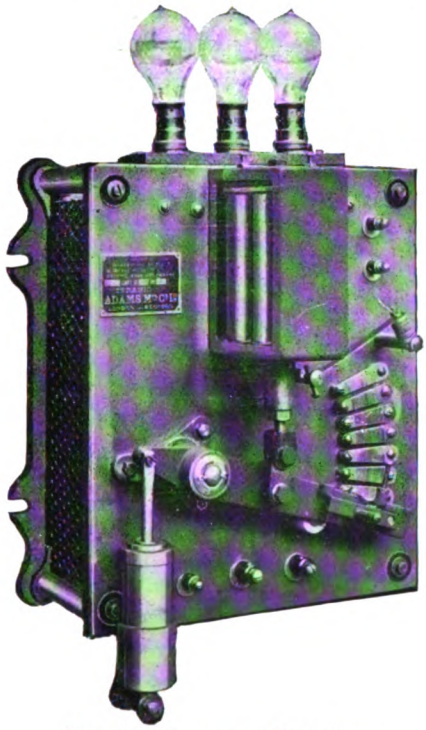

Fig. 4.—Automatic Starter.

the machine is turned on; this closes the circuit through the solenoids of the main switch and the starter. For damping the movement of the starter arm, as can be seen from Fig. 4, an oil dash-pot is provided. When the arm has risen so far that all the resistance is cut out, one of the lamps shown in Fig. 4 is automatically inserted in series with the solenoid, so as to cut down the current to the value necessary to hold up the plunger, and thus prevent undue heating of the solenoid. On turning off the tumbler switch to stop the machine, the main solenoid switch, which is illus-

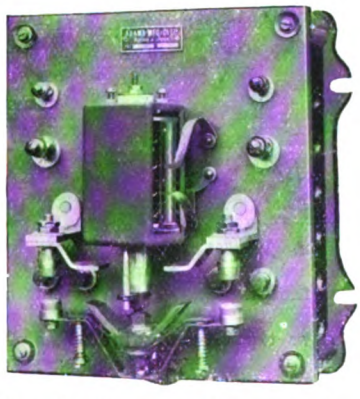

Fig. 5.—Solenoid Main Switch.

trated in Fig. 5, is released. This, as can be seen, is provided with a carbon break and magnetic blow-out. When first starting the machines, and while "inching," the main circuit must of necessity be made and broken several times in succession. A modification of this system of control has been fitted to one of the machines, and has proved so successful that the other machines will soon also be fitted. As the starting and stopping is effected by means of an ordinary tumbler switch on the machine, if the main fuse blows, or for any reason the main switch is opened, the machine stops, but would start again on closing the main circuit, as the operator would probably forget to throw over the tumbler switch, and thus break the control circuit. Mr. Oliver Holt, the electrical engineer in charge at these works, remedied this, however, by substituting for the tumbler switch a small switch with a no-voltage release, the coil of which is in series with the motor shunt field circuit as usual. A small button at the side of the switch-box permits of this coil being short-circuited, which allows the switch to open and break the control circuit, thus stopping the machine. This modified control switch has been in operation for more than a year, and has given every satisfaction.

Besides the above-mentioned printing and other machines there are two lifts worked by a single 5-h.p. motor. As these lifts were originally driven by a fast and loose pulley arrangement from the power shafting, it was found most convenient to retain the former arrangement and run the shafting for the two lifts with a single motor. This motor is provided with an automatic control system similar to that in use for the printing machines. In order that the lift man may know that the motor is up to speed before he starts the lift by shifting the belts, two lamps are put on every floor. One of these lamps is in series with the solenoid of the main switch, and the other is in series with the starter solenoid, but is put in circuit only when the starter arm is on the full voltage position as explained above. All the starters and regulators which have been mentioned are of the Adams Manufacturing Co.'s make.

Goldsmith Street Building.

This building is the home of what is known as the Requisite Department, and contains 23 motors with an aggregate power of somewhat over 90 h.p. These motors drive folding, cutting, and small printing machines, all of which were formerly driven by one gas-engine. The lighting arrangements of this building were carried out by Messrs. Tyler & Freeman, and include an installation of about two hundred 200-volt carbon-filament lamps. A Smith & Stevens 12-h.p. goods lift is installed here.

Works Department.

The Works Department is situated in a large building in Water Lane, Strand. In the carpenter's shop here there are various tools, belt-driven from separate motors. A variable-speed circular saw is driven by a 7-h.p. motor with shunt field regulator. Most of the machines have "Brookhirst" starters with a worm and wheel gear resembling that of the Adams Manufacturing Co. described in a previous section. These starters are provided with emergency stops, by pressing which the no-voltage release coil is shorted and the machine stopped. All are totally enclosed in iron cases with glass fronts, the handle and emergency stop only being accessible. There is nothing remarkable about the lighting arrangements in this building. About 200 lamps are installed, mostly carbon filament. In this department there is a Smith & Stevens slow-speed goods lift worked by a 2-h.p. motor. A chaff-cutter in the stables is also electrically driven, a totally enclosed 6-h.p. motor being employed for this purpose.

Library Department.

The building in which the library books are stored, and which is adjacent to the Water Lane building, has been recently re-wired, and about 280 tantalum lamps are used here. The lighting of the passages between the bookshelves is carried out with pendant lamps and cord operated trigger switches adjacent to the ceiling roses. On each floor is a master switch. For raising the books to the upper floors a Waygood lift is pro-

Digitized by Google

vided. On the top floor is a 3-h.p. electric winch for loading and unloading goods.

News Department.

The News Department is situated in the original building in the Strand. The lighting of the ground floor is by nine small enclosed arc lamps supplied by the Westminster Engineering Co. The upper floors are illuminated with tantalum lamps, of which about 350 are employed. To bring up the parcels from the basement to the ground floor there is a 3-h.p. elevator, constructed in the form of an endless canvas belt with cross-battens of wood. There is also a Waygood push-button lift for books, and a large Fryer goods lift.

In the preparation of this article we have to acknowledge the courtesy and assistance of Messrs. W. H. Smith & Sons and their staff, and also of Messrs. O'Gorman and Cozens Hardy, the consulting electrical engineers.

NEW APPARATUS FOR THE MAGNETIC TESTING OF IRON

A NEW form of apparatus for obtaining the magnetisation curves and the magnetic constants of samples of iron and steel is described by Prof. Gisbert Kapp, in a recent issue of the *Elektrotechnische Zeitschrift*.

All those types of magnetic testing apparatus in which the sample of iron is introduced in the form of a rod or bar, suffer

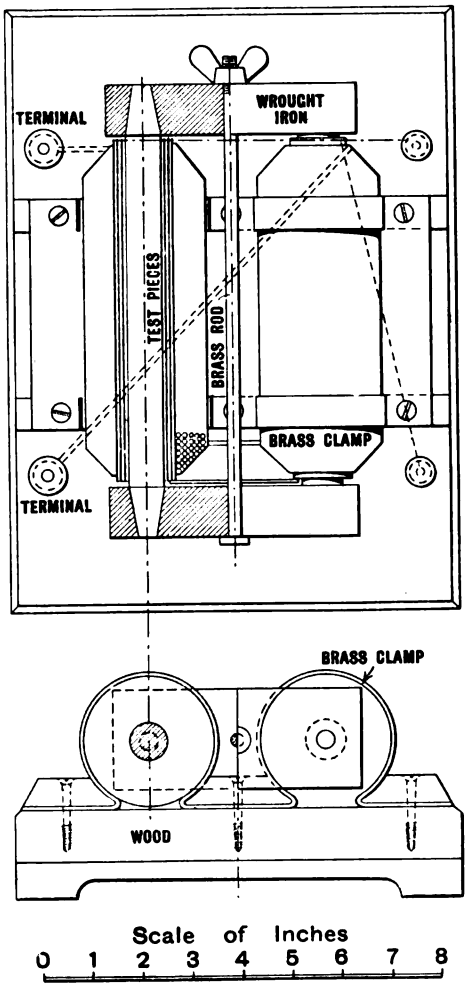

FIG. 1.—APPARATUS DESIGNED BY PROF. KAPP FOR THE MAGNETIC TESTING OF SAMPLES OF IRON.

from two important sources of error: the first lies in the fact that there is generally a bad magnetic joint between the rod and the yoke, and the second in the fact that the ampere turns necessary for the yoke cannot be allowed for exactly. With the classical apparatus of Dr. Hopkinson, these errors may be considerable. In that pattern, two rods are arranged axially, and butt together in the middle; the magnetic resistance of this joint, as also of that at the openings in the yoke through which the rods are introduced, is very uncertain in value, and not always so small as to be negligible. The yoke itself also is long, and a certain number of ampere-turns are required to force the flux through it. In order to reduce the importance of these errors, some workers in this field have constructed apparatus in which the two rods of iron to be tested are arranged side by side, and connected by short yokes of comparatively large section at both extremities. The apparatus, designed by Prof. Kapp, and illustrated in Fig. 1, is of this pattern.

The two yoke pieces are separate, and are provided with conical holes to take the ends of the test pieces. In order to get good magnetic joints between the yokes and the rods, the two yokes are drawn together by means of the central screw, as shown in the drawing. It has been found quite unnecessary to tighten the screw, however. On each rod is a wound bobbin consisting of two coils: an exciting coil of thick wire, and a testing coil of fine wire. The testing is carried out in the usual way, with the aid of a ballistic galvanometer or a Grassot's fluxometer. A small correction is necessary on account of the air-space between

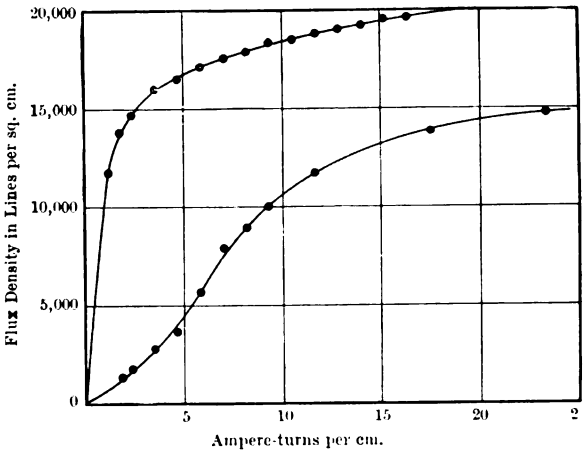

FIG. 2.—MAGNETISATION CURVES TAKEN WITH PROF. KAPP'S APPARATUS.

the rod and the testing coil. In the apparatus described, the flux in this ring space amounts to $45 \times C$, where C represents the exciting current. The number of ampere-turns required for the yoke pieces works out at 1/3000 of the value of the total flux, as shown by the galvanometer. If this latter is represented by Φ_1 and the actual flux in the rod by Φ; then:—

$$\Phi = \Phi_1 - 45\ C,$$

and the flux-density in the sample will be:—

$$B = \frac{\Phi}{\text{section of rod}}$$

The ampere-turns acting, as the total number of turns is 840, will be equal to—

$$(840 \times C) - \frac{\Phi_1}{3{,}000}$$

and the ampere-turns per centimetre or per inch can then be obtained by dividing by the total length of the rods. In Fig. 2 are given two magnetisation curves taken by means of this apparatus on two samples of wrought iron.

As can be seen, the points lie well on the curves. Slight variations are to be expected when the flux-density is below 5,000 lines per sq. cm., as the influence of previous magnetisations on the yoke is then felt. However, the most important part of the curve is that corresponding to densities over 10,000 lines per sq. cm.

New Danish Duties on Electrical Goods.—The new Danish Tariff Law, which is to come into operation on January 1st next, has been translated by order of the British Parliament. The following table shows the duties on electrical goods under the existing tariff and the new tariff:—Electric machines and parts (dynamos and electromotors): Existing tariff, 10 per cent. ad valorem; new tariff, 7½ per cent. ad valorem. Engine packing and insulating materials: Existing tariff, 10 per cent. ad valorem; new tariff, 5s 7½d. per cwt. Wire for electrical purposes and cables, and all kinds of wire having paper, textile, or other material spun round, woven in, or twisted round it: Existing tariff, 2s. 4½d. per cwt.; new tariff, 7½ per cent. ad valorem.

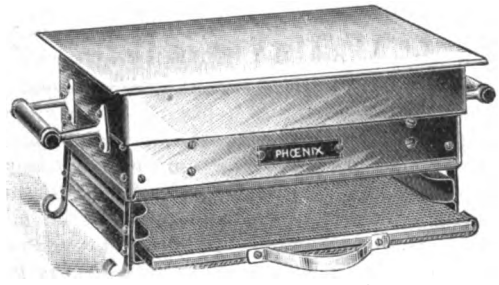
ELECTRIC COOKING AT A LONDON RESTAURANT

AN experiment of some considerable interest to electrical engineers is now being carried on at one of the Oxford Street branches of James Fleming's Restaurants, Ltd. In one window of the premises at 68 Oxford Street there is a display of electric cooking, and all the chops, steaks, poached eggs, &c., for this restaurant are cooked by electricity. As Mr. Fleming, the managing director, has informed us, this experiment is being made, in the first place, to determine the practicability of electric cooking on a large scale as regards convenience, economy, cleanliness, and success from the epicurean's point of view: the display is quite a secondary matter.

Power is taken from the mains of the Marylebone Borough Council, the electricity department of which has not only done the necessary wiring free of charge, but has lent meters for registering separately the consumption of each piece of apparatus.

The apparatus at present in use consists of an oven, a large grill measuring 15 in. by 10 in., and consuming 1,800 watts when hot, an egg-poacher, 6¼ in. diam., consuming 600 watts when hot, a toaster, and a 6¼ in. hot-plate. All these were supplied by the Phœnix Electric Heating Co., Ltd. The most interesting piece of apparatus is the large grill, which is illustrated below, and is constructed as follows:—Under the nickel-plated cover is a pad of asbestos wool some two inches thick, beneath which is a metal reflector. A grid of spirally-wound resistance-wire is supported from



NEW PATTERN OF ELECTRIC GRILL.

the latter on small porcelain buttons, and the heat is reflected down on to the chop or steak placed on a grid below. The wire is red-hot under normal conditions, and keeps remarkably clean in use, as, contrary to the usual grill-room grill, the heat is directed on the meat from above, and the fat drips downwards, and not on to the fire or its equivalent. In order to economise at "light loads," the resistance wire is divided into two sections, either or both of which can be switched on. The grid for carrying the chops or steaks, as can be seen from the illustration, can be put in at various levels. The whole stands in a tray for catching the surplus fat. The first form of grill used was that in which the chop was laid on a heated corrugated iron grid, but this type had several disadvantages, the most important of which was that a film of fat remained on the grill, and continued to burn during the operation of cooking. In the new pattern, with the heating grid above the chop, this trouble is eliminated, and the food is well and cleanly cooked. The toaster resembles the grill in general design. The bread is thus not in contact with the heating element as is the case with gas-heated toasters and some electric ones, and another important point is that the toaster is open all round, which, although allowing heat to escape, and, therefore, to the prejudice of efficiency, prevents the bread from being "stewed," and the toast is real toast.

A five-gallon copper boiler will also be used for keeping water at the boiling point. This consumes 1,000 watts, and will only be employed for keeping the water at its boiling temperature, and not actually for boiling it. Mr. Fleming has sent us the following report on the results for the eight days commencing Wednesday, September 2nd, and ending Thursday, 10th, inclusive, with the exception of Sunday, September 6th. During that time the plant was in use almost continuously from 12 noon till 9 p.m. daily. The average daily consumption of the oven which has been in use only for keeping the plates hot, was 8¾ units, of the egg-poacher 5⅛ units, of the grill for chops and steaks 13½ units, and of the small grill for toasting bread and the boiling plate use for poaching eggs, &c. (which are both connected to the one meter), 11¾ units. The total consumption was 313 units, making an average daily consumption of 39⅛ units, which, at 1⅛ pence per unit, makes a daily cost of 3s. 8d. for current, or about 9d. per day, or 1d. per hour for each grill, boiling plate, and oven in use. For the egg-poacher, small grill, or boiling plate, the cost, however, is only about ¾d. per hour. For the large grill, which is capable of cooking twelve chops or steaks at one time, the cost per hour is slightly over 1½d. This grill in the eight days referred to was made to cook 678 chops and steaks at a cost for current of 3/16 of 1d. per chop or steak.

The average cost of 1⅛d. per unit is derived as follows:—The Marylebone power rates are 2d. per unit for the first 125 hours per quarter of the maximum demand, and 1d. for the remaining units, and under the conditions of the present case this works out at about 1⅛d. per unit. It must be remembered that in the case under consideration one of the chief advantages of electric cooking—namely, that cooking can be done at a moment's notice, without the necessity of maintaining a fire—does not come into the question, as cooking is being done nearly continuously from noon to 9 p.m.

As is well known, grilling on a gas stove is nearly always unsatisfactory, owing to the inevitable taint from the gas. On the other hand, Mr. Fleming informs us that electrically cooked chops and steaks have been pronounced by some epicures to be even better than those cooked on a coal or coke fire. No trouble has been experienced with the apparatus, and it is worthy of notice that, in spite of the fact that no ventilating hoods have been provided, there is no unduly strong odour of cooking.

The Marylebone Electricity Department has also installed a small equipment at the "Green Man," Euston Road, some apparatus will be shortly put on trial at one of Slater's branches, and negotiations with several other dining rooms are in progress.

Electrification of the Baden Railways.—In last week's issue we inserted a note to the effect that the Baden State Railway authorities had decided to introduce electric traction on the main line sections, Basle-Schopfheim-Zell and Schopfheim-Säckingen. We have obtained the following further particulars from the *Elektrotechnischer Anzeiger*. A water-power station is to be erected at Augst-Wyhlen, on the Rhein, and from there the power will be transmitted in the form of three-phase alternating current to Basle. At Basle transformation to single-phase at 10,000 volts, 15 cycles will take place. The Siemens-Schuckert Werke have obtained the contract for the sub-station, the feeder system and the overhead equipment of the section Basle-Schopfheim, and ten 1,000-h.p. locomotives. The overhead equipment of the section Schopfheim-Säckingen will be supplied by the Allgemeine Elektricitäts Ges. Brown, Boveri & Co. will supply two further locomotives, and the transmission line from the power station to Basle will be erected by the Felten-Guilleaume-Lahmeyerwerke.

THE ELECTRIFICATION OF THE VICTORIAN RAILWAYS

IN our issue of August 27th last we gave some particulars of the proposed electrification of the suburban railways of Melbourne, and mentioned that the report of the consulting electrical engineer, Mr. Merz, to the Victorian Railway Commissioners would soon be ready. An official summary of this report has now been issued, and was published in the last issue of the *Railway Gazette*.

The report deals with two main questions: First, is electrification financially justifiable? and secondly, which is the most suitable system in the case under consideration?

After referring to the exceptional importance of the suburban business in the case of Melbourne as compared with other great cities, the principal features of electric working generally, and the advantages which it offers both to the travelling public and to the management, are dealt with at length. It is shown that electrification allows for a more frequent service throughout the day, and the running of trains at regular intervals, as well as greater punctuality and safety in working. Fires from locomotive sparks, and smoke, steam, and dust, would be practically abolished, while the lighting and heating of the carriages would be much improved. In addition to this, journeys would be shortened by 15 to 30 per cent. Following on this are elaborate technical investigations and calculations both as to the first cost and the working cost of the Melbourne system with electric traction as compared with steam, and a list is then given of the improvements in the time-table which can be brought about. As showing the improved services which electric traction offers, the journey from Flinders Street to Sandringham takes 38½ minutes with steam, and would take 31 with electric traction; to Williamstown, 37 minutes with steam, 31 with electric; to Camberwell, 21 minutes with steam, 17 with electric; and other journeys in proportion. Instead of 70 trains a day to Essendon, there would be 88 with electric; instead of 40 to Williamstown, there would be 75 with electric; instead of 28 to Sandringham, there would be 73 with electric; and other routes with corresponding improvements.

The main conclusion is that on account of the great advantages to the public, and the improvement in financial results to be expected from electrification, the installation of electric traction on the suburban railways is desirable on grounds of finance and of public convenience, and it should be carried out in the following stages:

I. The Port Melbourne, St. Kilda, Sandringham, and Broad Meadows branches. Route length, 29 miles.

II. Stage I., and, in addition, the Camberwell and Williamstown branches. Route length, 65 miles.

III. The complete scheme including, in addition to Stage II., the Sunshine, Coburg, Preston, Heidelberg, Dandenong, and Mordialloc branches. Route length, 124 miles.

Mr. Merz considers it would not be convenient to try and convert more than the lines in Stage I. at first, nor financially advisable to convert less than the lines in Stage I.

The following is the summary of conclusions appended to the report:—

CAPITAL OUTLAY.

(1) The total capital outlay for the conversion of the whole suburban system will be £2.227,050. It is recommended that a portion only of the system be converted at present.

(2) In considering these figures, the expenditure necessary if steam traction be retained must also be taken into account. This expenditure, on rolling stock only, amounts to £408,358.

COST OF ELECTRIC WORKING.

(3) The expenses per train-mile with electric traction would be 11·0d., as against 18·9d. with steam. With the former, however, there would be a greater train-mileage.

(4) The total operating expenses with electric traction for the whole suburban service would be £27,267 per annum less than with steam.

FINANCIAL RESULT.

(5) The total annual expenditure for the whole service, including 4 per cent. on the new capital outlay, would be £44,791 more than with steam; against this must be put the additional revenue due to the improved service.

(6) The surplus, after paying interest on new capital for the complete scheme, would, with electric traction, be £40,251 greater than was obtained in 1906 with steam.

IMPROVED SERVICE.

(7) If electric traction be adopted, an improved schedule speed and frequency of service becomes possible with the existing tracks and termini.

(8) An increase of 20 per cent. over the present schedule speed and an increase of 71 per cent. in the train-mileage, are financially justifiable, and are covered by the expenses referred to above.

ROLLING STOCK.

(9) The adoption, instead of locomotives, of the "multiple-unit" system of train operation is recommended, giving this increase of 71 per cent. in the train-mileage, with an increase of only 23 per cent. in the ton-mileage.

(10) Cross-compartment coaches should be adopted, and the existing bogie stock be altered and used for the electric service.

(11) The total stock required would be 496 coaches with electric working, as compared with 546 coaches and 110 locomotives with steam, the reduction in the number of coaches being due to the higher schedule speed.

ELECTRICAL SYSTEM.

(12) A direct current 800 volt system would be the cheapest and best system for this particular case.

(13) The direct current should be distributed to the trains from sub-stations by means of a protected conductor rail.

(14) The sub-stations should be supplied with three-phase high-tension current from the power station by means of underground cables in the central areas, and by overhead lines in the less populous districts.

POWER STATION.

(15) The energy required should be generated in a central power station situated at Yarraville, designed to handle the load of 35,000 electrical horse-power.

(16) This power station should be designed to burn either black or brown coal, and the power plant consist of water tube boilers and steam turbines.

(17) The Spencer Street and Elsternwick Stations should be shut down, and the St. Kilda tramway and the existing lighting system be supplied in bulk from Yarraville.

(18) The Yarraville Power Station should be also used for the lighting of the railway stations and the driving of the Newport and North Melbourne workshops.

Digitized by Google

Initial Scheme.

(19) If electric traction be decided on, the scheme proceeded with in the first instance should consist of the Port Melbourne and St. Kilda and the Brighton and Essendon branches, involving, with power plant, an initial expenditure of £801,880.

(20) After paying interest on this sum, the surplus from these lines would, with electric traction, be £21,358 greater than was obtained in 1906 with steam traction.

(21) If steam be retained on these lines, £141,019 will have to be spent on rolling stock for them alone.

(22) The conversion of these lines should be so arranged that the electric zone might be extended to the other suburban lines at a future date, with a minimum of alteration and expense.

Other Operating Changes.

(23) Such questions as systems of train despatching, automatic signalling, new block sections, special provisions for race traffic, &c., would be best deferred until part, at least, of the system is being worked electrically.

PROSPECTIVE ELECTRIC POWER DEVELOPMENT IN NEW ZEALAND

(From a Correspondent)

WE have been accustomed in the past to underestimate the importance of New Zealand. It has had, it is true, the struggles of a young colony, but of late years its progress has been by leaps and bounds. Wealth and population have alike increased, and the total value of exports and imports last year attained a value of about £32,000,000. Moreover, this prosperity is based on a comparatively small area of development. The interior of the land has never been thoroughly prospected for mineral wealth, and there are vast tracts of land that have not yet been explored by the white man. As a matter of fact, we have before us at the present day a dominion in the making, and in practically the same position as was Canada before its wonderful grain-raising resources were opened up.

One very important feature which affects the development of New Zealand is the fact that it is a most Socialistic State. All royalties in the working of coal, gold, flax, and other natural products of the north and south islands are vested in the Government, and particular attention should be directed to the fact that the water supplies of the dominion have hitherto been conserved as a national asset. This is a factor which deserves very careful attention, and the main object of this article is to show that the water power of the colony, of which, on an estimate of experts, there is no less than four million horse-power available, constitutes the key to the future.

It should first of all be pointed out that there is a very strong pro-British feeling in the colony. This is shown in the general tenour of political speeches and newspaper articles of every shade of legislative opinion, and is carried out in a very practical manner in the business relations existing between us and our colony. This is indicated by the almost complete monopoly which we possess of the imports into the dominion, six-sevenths of the whole import trade being in the hands of England and her colonies, notwithstanding the fact that foreign countries have direct representation in the country by means of Consuls who are largely trade representatives, whereas England still conducts its official representation on the obsolete lines which have so often been protested against. This preference for the Old Country is very fortunate for us, inasmuch as foreign countries have already realised that in the water power of New Zealand lies one of the greatest opportunities of the twentieth century. The dominion Government has already been approached by an Italian syndicate on the question, while American experts have presented reports on the water facilities of New Zealand to their associations. Where Italy and America are alive it is only to be expected that the pushful German is also on the move to obtain possession. The only question seems to be whether England will stand aside until the best of the prizes have gone.

The position, briefly stated, is this. The new colonies of New Zealand have not at present reached sufficient strength and maturity to develop their own resources successfully unless assisted by outside capital. To "harness" the waterfalls of the country, and to provide suitable industrial outlets for the electrical energy so produced, would require an estimated amount of £10,000,000 sterling, and the obtaining of a loan for this sum is far too heavy a burden to be borne by the Government. The other alternative is to lease the water powers of the country to private capitalists, but at present the legislation of the colony is not able to permit this. Lately, however, a great move forward has taken place. At the opening of the New Zealand Parliament on June 29th of the present year the Premier's speech referred, almost in its opening phrases, to the rich national endowment of water power, and stated:—

"The expediency has been impressed on my advisers of permitting portions of the water power to be employed for private enterprise under strict and proper safeguards in the public interest. Proposals to this end will be shortly laid before you in the form of enabling legislation."

It is extremely probable that some measure to this effect will shortly be passed, inasmuch as support is being given to the proposal by newspapers of every shade of political opinion. The way in which the wisdom of discussion is endorsed by the Press may be shown by the following sentences from a leader in the New Zealand *Daily Telegraph*:—

It has been announced in Parliament by a responsible Minister, speaking from figures and under instruction provided by Government experts, that utilisation of our water power for one purpose alone, that of the manufacture of nitrates from the atmosphere, would enable the Dominion to do an annual trade exceeding in value the whole of our wool output. It is hardly necessary to allow for exaggeration here. What German capital and German enterprise are doing in Sweden and Norway at this moment is quite sufficient to show that New Zealand, given the necessary capital for harnessing our water power, could control prices in the world's market for nitrates."

The water power of New Zealand, if turned into electrical energy, will regenerate the country. To take a single instance, the wool industry is to the dominion what the coal and shipping trades are to us. It constitutes more than half its total exports, but the natural outcome of the wool industry is hampered in a desperate manner because coal is practically inaccessible for manufacturing purposes. The woollen articles used there have to stand the cost of freight over to England as raw material, and freight back again as manufactured goods. Moreover, a fluctuating duty has to be paid on these imports, having an average value of about 30 per cent. *ad valorem*, this being required under the present conditions to prevent competition with home-manufactured wool.

With electrical power at hand, New Zealand could,

Digitized by Google

by manufacturing on the spot, become the Bradford of the East, and speedily build up a big shipping trade to the Far East in woollens. Although New Zealand coal is amongst the best steam coals in the world, it must be remembered that the carboniferous district is principally located in the south island, and that the cost of carriage is not unimportant, so that there would be a considerable saving by utilising water power together with electrical transmission and distribution. The difficulty of obtaining coal in the northern parts of New Zealand is amply illustrated by the fact that it is the practice of ships from our own country to take a cargo out to Sydney in South Australia, ship a cargo of coal as ballast from Sydney to New Zealand, a distance of 1,500 to 1,600 miles, and then to bring back a general cargo from New Zealand to Sydney. Moreover, the cost of the distribution of electric power would be far less than here, as overhead lines could be used, and the difficulties would be less.

A few sentences will indicate what the application of electric power distribution might do for New Zealand. The production of nitrates and the development of woollen manufactures have already been mentioned. There is an immense saw mill industry, scattered over a wide area, and lending itself most admirably to the facilities for cheap power afforded by electrical transmission. On the east coast there is a deposit of "iron sand" about 180 miles long, aggregating millions of tons, containing a large ferric percentage which experiments have proved capable of producing iron equal to the best Swedish. This industry is at present untouched, owing to the inadequacy of present methods of smelting the ore, and if electricity can be rendered available, there is no doubt that a second Middlesbrough will be the result. There is already a large demand in New Zealand for agricultural implements which could thus be manufactured on the spot. The railways require cheap electrical power in place of dear coal.

All, or nearly all, the railways are State-owned, the small lengths of private lines, some two or three hundred miles, being steadily acquired by the State as opportunity serves. The harbours and practically all the public works belong to the new Zealand Government or to local authorities. All these undertakings could use electric power with advantage. Neither the Government nor the local authorities can afford to lay down a supply of electricity themselves, so that in this one item alone there is a tremendous field for private enterprise.

Power is also required for the large frozen meat industry, while the butter and cheese trade of New Zealand must inevitably develop on the Danish system in which large depôts will be founded in which the milk will be converted into butter by means of electrically operated centrifuges. The coal mines themselves will be operated electrically, following the example of Germany and England, while the tramway systems of New Zealand, which are a profitable market for electrical power, are at present only in their infancy.

GOVERNMENT COMPETITION WITH CANADIAN POWER COMPANIES

WITH regard to the proposition of the Provincial Government of Ontario to furnish electric power from Niagara Falls to the municipalities of that province, within a radius of 150 miles, the American Consul at Hamilton writes to the following effect in a report upon this subject :—

The Government Commission, composed of two members of the Cabinet of the Ontario Government, has charge of this matter, and has given it careful study and attention. The Commission has in its service expert electrical engineers, who have spent a year or more in estimating the possible cost to the municipalities as their share for the construction of the power line from Niagara Falls to the several points of delivery. This cost is to be shared *pro rata* between the municipalities entering into the scheme. It is proposed to furnish the electric energy to the municipalities at the price for which the Government contracts it from the supplying company at the Falls, to which is to be added the necessary expenses for maintaining the line and keeping it in working order. An extra charge is to be added for the construction of the line, which will continue to be a fixed charge for thirty years. At the end of that period the transmission line becomes the joint property of the municipalities, who will thereafter pay all necessary costs for upkeep and management, as well as for the electric power furnished, the Government retiring from further control in the matter. Although no definite figures of cost have been given, the expectation of the Government Commission is that it will be so low that the expense to manufacturers will be less than that of steam power, there being no coal supply in Ontario.

Hamilton is the first important point at which power would be furnished by the Government, and the lowest estimate per horse-power, delivered here, is $17·80 per annum. The cost would increase to other municipalities in proportion to distance from the source of supply and the expense of construction and upkeep of the transmission line. The Government contract proposes to bind the municipalities for a period of thirty years not to contract with any private company or corporation for a supply of electric power. In the city of Hamilton there is a company which began in a small way many years ago to furnish electricity derived from its steam plants for street lighting and for the street railway system. Less than ten years ago this company utilised the water power at Decew Falls, 34 miles from Hamilton, constructing a power house, machinery, buildings, and a pole line to this city for the transmission of electrical energy. Contracts were made with the manufacturing establishments to furnish them power at a price far below the cost of steam power, and now there are very few factories, and those only small affairs, that are not run by electricity. Natural gas, with which this city is supplied, furnishes a cheap power to small users.

The city of Hamilton is now proposing to instal electric power to operate the waterworks system and the sewage disposal plants instead of steam, and to that end a by-law was passed by the City Council on July 17th authorising a contract to be made with the local company for power at the rate of $16 per horse-power-year. An effort was made by the advocates of the Government power system to contract with the Government, but as the Government could not yet make even an approximate offer at what price electric energy would be furnished, the City Council accepted the proposition of the local company. As the contract for street lighting will shortly expire, this question was also settled by by-law. The city has been paying $80 a year per lamp for all-night service during the entire year for 460 lamps. Under the new contract the city will be supplied with light at $47.50 per lamp of 2,000 candle-power, and the number of lamps will be largely increased.

These contracts are made binding for periods of five years, the city having the power of renewal at the end of each five years for twenty years by giving the company due notice. The city can abrogate the contract at the end of any five years, while the company may be held for the full period. In the contracts the city has provided for ample protection to the private users of incandescent lighting and to the manufacturers, so that the company cannot take advantage of them and raise their rates. It is probable that the City Council could not have made such favourable contracts had it not been for the prospective construction of the Government transmission line from Niagara Falls.

Hamilton is substantially a manufacturing city, having now nearly 300 large manufacturing establishments, largely built up during the past eight years as the result of cheap power. They are mainly controlled by American capital, induced to locate here by reason of cheap power, and are managed by American experts. About $35,000,000 capital is employed, furnishing labour to over 10,000 men and women in the factories. The bonded debt of the local power company is held by capitalists in the United States. The City Council and the company are negotiating for a rebuilding and equipping of the street-car lines, increasing the mileage, and the purchase of new cars. To enable the company to undertake the cost at this time the city has agreed to guarantee the bonds of the company to the amount of $500,000. The contract is that the company shall provide 50 new cars of up-to-date construction, one-half of that number to be double trucks.

Meat Curing by Electricity.—The Acting British Consul-General at Chicago (Mr. T. Erskine) reports that a process of curing meat by electricity has been perfected which has proved successful enough to induce the formation of a company to put it on the market. The building of a model plant to demonstrate the new process was recently begun in Cleveland. The promoters of the process say that it does not change the method of soaking, but hastens the penetration of the meat by salt; bacon, for example, which under the old process takes twenty days to cure, can, it is claimed, be cured by the new method in two or three days. In addition to saving much time, the process is said to be extremely sanitary.

THE BRITISH ASSOCIATION MEETING

An Attack on Electric Tramways

IN our last issue we reported the first Papers and discussions at the meeting of the British Association for the Advancement of Science, held in Dublin from September 2nd to September 9th. Of the remaining Papers, one only was of direct interest to the electrical engineer—namely, an essay on "General Urban and Inter-Urban Transportation and Railless Electric Traction," by Mr. F. Douglas Fox, who is connected with the company now endeavouring to introduce into this country a system of electric trolley traction in which electric motor omnibuses running on roads take current from an overhead trolley wire. The Paper, of which we give an abstract below, advanced arguments to prove that this system was more economical than other forms of mechanical traction, but did not go deeply into the engineering side of the subject, nor did it explain why this system, which has been before the public for many years, has only been adopted in a few isolated instances. The Paper, in fact, consisted in the main of a general analysis of municipal electric tramway accounts, upon which the author based a determined attack on electric tramway traction in general, and municipal tramways in particular.

MR. F. DOUGLAS FOX commenced his Paper with a general survey of the present methods of mechanical traction.

The cost of construction of electric tramways, he said, has been steadily mounting up, and even in its most economical form the cost of the permanent way exceeds that of some railways. The mechanical omnibus, he contended, can be installed for less than half the cost of a tramway; its working expenses are somewhat higher; but, the author argued, when interest on capital is combined with working expenses and both together are reduced to cost per car-mile, there is not much margin between the tramway and the petrol 'bus. If, however, the mechanical omnibus were no more than on a commercial parity with the tramway, it would, if there were still a clear field and no favour, be preferable on account of the lower capital expenditure.

Mr. Fox continued: This country has, however, committed itself heavily to the tramway system, having embarked capital in it to the extent of about 35 millions of municipal indebtedness, 10 millions of companies' obligations, and 20 millions of preference and ordinary stock. In other words, the cream of urban traffic has already gone to the tramway. The motor-omnibus cannot now displace its rival, but must look for its field with some exceptions either to the smaller towns or to suburban extensions of city tramways, or to foreign countries. Since the denser and more remunerative traffic is already dealt with, the motor omnibus should, in order to succeed in Great Britain, be able to pay with a lower revenue than the average of the tramways.

As to the technical features, on the one hand, a railway is an unnatural adjunct to a city street. On its own right of way it is unexceptionable, but in the midst of a public thoroughfare it interferes with a dense, heterogeneous traffic, during construction, operation, and repair. On the other hand, the tramcar as at present designed is superior to the motor omnibus in comfort and capacity. The latter can handle an enormous traffic, it can travel quite as fast as is consistent with safety, and in point of comfort has been recently greatly improved. It is, however, limited as to its capacity from respect for the road surface, to one-third the weight permissible on the tramway.

Capital has up to the present time only been embarked in the mechanical omnibus to any large extent in that form where the petrol or steam motor is used. In London alone some 3½ millions of capital have been invested, which, at the market quotations, would appear to have a present value of about one million. There can be little doubt that the motor omnibus was bound to come, but it seems to have come too quickly. There is no restriction to public carriers on highways such as there is to railway companies, and mutually destructive and competitive undertakings in the form of omnibus lines can be carried on to any extent. When capital poured into motor omnibus companies, the existing horse omnibus companies were driven into adopting them also, to the prejudice of their commercial standing. The 3½ millions of capital above mentioned do not include that of many companies which have disappeared.

In the 71 of the 75 corporation-owned tramways, statistics of which are given in the Paper, the working expenses vary from about 4½d. to 8½d. per car-mile. The capital charges of interest, sinking fund, and depreciation vary from 2d. to 5½d. per car-mile. The averages of these data are 6·34d. and 3·62d. respectively. These two figures added represent an average minimum remunerative revenue of 9·96d. The actual average revenue obtained is 10·52d. per car-mile. Thus the average net profit barely exceeds ½d. per car-mile.

In the petrol omnibus the working expenses and depreciation together are estimated at 10·86d. per car-mile. Adding to this interest and sinking fund at 6 per cent. of the invested capital, the minimum remunerative revenue is estimated at 11·7d. per car-mile, and this is based on a somewhat sanguine view of the costs of maintenance. The variation is great, and under certain conditions the figure might be well over 1s. per car-mile. In the tramway list considered, there are only 10 out of the 71 cases in which the traffic receipts reach 11·7d. per car-mile. On the other hand, directly an omnibus line is able to earn a profit at all, each ½d. per car-mile, when reduced to percentage on its much smaller capital, means three times as much profit as it does on the tramway.

The electric omnibus with accumulators (popularly known in London as the "Electrobus") is estimated as capable of meeting its expenses and depreciation at 9·5d. per car-mile, and adding to this a 6 per cent. allowance for interest and sinking fund, the minimum remunerative revenue becomes 10·25d. per car-mile. In the tramway list there are 35 of the 71 in which the traffic receipts reach this figure.

The electric omnibus with overhead wires, the trackless trolley system, is estimated as a possible paying concern with a revenue of from 7d. to 9d., according to class of construction. In the tramway list there are 65 which have a revenue of over 7d. and 50 of over 9d. per car-mile.

As an example of the wide field of public highways which await occupation by improved methods of mechanical transportation, the author said that in India alone, there are 150,000 miles of good roads, upon which both passenger and goods traffic could be handled upon a prodigious scale.

To estimate the working expenses and fixed charges of petrol omnibuses, Mr. Fox made use of the estimates given in a Paper read by Mr. W. G. Hardy before the Society of Road Traction Engineers in December of last year, and published in the January number of the *Tramway World*. This estimate is admittedly based on experience with a comparatively small number of mechanically propelled vehicles.

The details of Mr. Hardy's estimate are as follows:—

MOTOR-OMNIBUS ESTIMATE.

Number of cars in stock	20	
Number of cars in service	13	
Total capital expenditure	£25.000	
Car-mileage per annum	425,880	
Receipts per car-mile	12	pence
Total Receipts	£21,294	
Working expenses per car-mile	9·449d.	
Depreciation per car-mile	1·407d.	
Working expenses and depreciation per car-mile	10·856	pence
Total operating expenses	£16,772 3s. 4d.	
Depreciation, 15 per cent.	£2,497 10s. 4d.	

The details of the operating expenses reduced to car-mileage are as follows:—

Petrol, carbide, grease, and oil	1·600	pence
Rubber tyres	2·000	,,
Drivers and conductors	1·801	,,
Ticket checks	0·163	,,
Attendance on 'buses	0·528	,,
Attendance at garage	0·132	,,
Repairs to chassis (including engines)	0·602	,,
,, ,, ,, Materials	1·000	,,
,, ,, ,, Bodies	0·113	,,
,, ,, ,, Buildings and tools	0·088	,,
Lighting and power	0·059	,,
Sundries	0·161	,,
Rents, rates, taxes, and insurance	0·564	,,
Salaries and Management	0·638	,,
Total	9·449	pence
The depreciation taken at 15 per cent. per annum works out at per car-mile	1·407	pence

Digitized by Google

The minimum cost of working of a fleet of this size is therefore, according to Mr. Hardy, 10·856d. per car-mile, leaving, out of a revenue of 1s. per car-mile, 1·144d., or on 425,880 car-miles a profit of about £2,000 per annum, or 8 per cent. on the capital.

The following estimate of the costs on a tramway of equal capacity, and with a length of track, frequency of service, and average speed corresponding with a traffic density such as would yield receipts as high as 1s. per car-mile is next given. Instead of Mr. Hardy's speed limit of 7½ miles an hour, however, which the author considers is too high for such conditions of general traffic where a revenue of 1s. per car-mile could be earned, a headway of five minutes has been taken, and an average speed as near to 7 miles per hour as will correspond with 13 cars and a length of route of 3·75 miles, double track. The capital expenditure per mile and the working expenses per car-mile have been taken at the average of the 71 corporation-owned tramways already referred to. The depreciation has been taken at £400 per annum per mile of single track.

COMPARATIVE TRAMWAY ESTIMATE.

Number of cars in stock	20
Number of cars in service	13
Length of track (double line)	3·75 miles
Capital expenditure	£88,000
Time interval between cars	5 min.
Average speed	6·93 m.p.h.
Receipts per car-mile	12d.
Working expenses per car-mile	6·34d.
Depreciation	1·69d.
Total receipts	£21,294
Working expenses plus depreciation	£14,250
Gross profit	£7,044
= 8 per cent. on the capital.	

Thus, the Paper continued, the commercial results of the motor omnibus line and the tramway work out at an equal rate of profit on the investment, the amount of capital in the case of the motor omnibus line being less than one-third of that of the tramway. As regards the estimated receipts taken in both cases at 1s. per car-mile, this is quite a possible revenue in London streets, but by no means an ordinary one in comparison with general tramway statistics. Out of the 71 cases considered, there are only 6 in which the receipts reach this figure. It has been assumed, moreover, in the comparison that the business done by the motor omnibus is equal to that done by the tramcar, although the latter is of much greater capacity. This is an anomaly which is supported by fact in London, but cannot be regarded as of universal application. Although comparative estimates of such diverse systems of transportation are difficult to make, the preceding comparison at least shows that the petrol omnibus has not as yet proved itself a more economical method of transportation than the tramway. The Paper then dealt with the "Electrobus" :

The "Electrobus," which has now been running for the best part of a year in London, is probably a more formidable rival than the petrol 'bus, not only to the horse omnibus but also to the tramway. The results of six months' running were examined by Sir Douglas Fox and Partners, in conjunction with Mr. T. Graham Gribble. Certain points of importance which have all previously been the subject of much controversy were in this examination fully established :—

1. That the vehicle, which (when fully loaded, with its complement of passengers) weighs 7½ tons, can do 40 miles without any distress of the batteries.

2. That the current consumption upon London streets, after allowing for all losses, does not exceed that of the average tramcar.

3. That the wear and tear of the chassis, including motor, is moderate as compared with that of the petrol 'bus.

4. That steep gradients, such as that of Ludgate Hill, are easily overcome with a full load on, and with no apparent distress of the battery.

The batteries were the property of and were maintained by two well-known accumulator companies on a mileage contract of 2d., and the representatives of these companies stated that they were very satisfied with their contracts. One of these gentlemen also stated that at this figure a life of six months was sufficient to pay for the batteries, some of which had already run that time and were still in good condition. The operation of the line, up to the time when the tests were made, had been more or less experimental, but sufficient data were available for making an estimate of the cost of operating a service of 100 'buses under similar conditions of duty. A business of considerable magnitude is obviously necessary in order to cover the cost of superintendence and skilled labour at the charging station, but, assuming a garage of 100 'buses, with a total performance of 2,400,000 car-miles per annum, there appears from the probable net cost of the batteries, and their apparent life, to be good grounds for regarding the mileage contract of 2d. as well within the powers of the battery company to continue indefinitely.

The general conclusion of the studies and tests made was that such a fleet of 100 electric omnibuses could be operated at an expenditure of 9½d. per car-mile, including maintenance and depreciation. The capital expenditure may be assumed at £125,000, upon which 6 per cent. for interest and sinking fund would come to 0·75d. per car-mile, thus making the minimum remunerative revenue for such an installation 10·25d. per car-mile.

With regard to current consumption, as against the loss in charging and discharging batteries should be set the favourable feature of the possibility of charging at night time when the demand on the central station is at its lightest, and consequently current has been offered to the Electrobus Company by a municipal central station at a very low figure. The many attractive features of the electric omnibus as compared with the petrol omnibus must dispose everyone interested in urban transportation to wish for it all the support, moral and financial, necessary for its development and perfection.

The principal improvement still to be looked for is the extension of the capacity of the battery without additional weight, and to the performance of a full day's work with one charge. It can now do 40 miles regularly with one charge. The Electrobus has performed the journey from London to Brighton, of 50 miles, without any distress.

However much the electric omnibus, driven from accumulators, may yet be improved, the cost of the batteries added to that of the rubber tyres, will in all probability limit its use to those circumstances where a fairly good revenue is to be obtained. The possibility is still a remote one of battery power being reduced in cost, and of some cheap substitute for rubber being found as together to reduce these items of working expense to a level with the cost of operating cars upon rails.

After this introduction the author gave the following account of one of the electric trolley omnibus routes on the Continent.

On the Continent of Europe, numerous installations of electric road traction are in operation for the transportation of both goods and passengers, in which the driving current is obtained from aerial conductors, and taken by a swivelling contact boom, having sufficient lateral freedom to enable the car to deviate in either direction sufficiently to pass other vehicles. These installations date from the year 1901, and each year sees not only fresh lines opened, but also installations of greater importance are being undertaken. Seven of these lines are in operation in Germany, one in France, and three in Italy. The Italian Government is said to have in contemplation the utilisation of the public highways for this mode of transportation upon an extended scale.

One of the latest of the projects, now well on the way to completion, is that of Mülhausen in Alsace. The city, of 100,000 inhabitants, is already supplied with a tramway system, but it was found necessary to connect the suburbs with these tramways and also with one another. It was also desired to obtain better access to the Public Gardens during the summer months. The traffic was, however, estimated to be too light to render a tramway profitable. The line to the Public Gardens has gradients as steep as 1 in 12; the zone line is comparatively flat. The estimates were to include a fixed charge of 4 per cent. interest upon capital. The Corporation appointed a commission to report first as to whether any means of communication could be made remunerative, and secondly, as to what means to adopt.

The complete scheme was to be for 6¾ miles of route, on which 550,000 car-miles were to be made per annum. The commission reported on three alternative proposals :—

1. For a very cheaply constructed tramway, for which plans and specifications were prepared by their own engineer.

2. For a service of motor omnibuses operated by benzine engines, for which several tenders were made by manufacturers of these vehicles.

3. For a "railless traction" line of electric omnibuses with aerial conductors.

The conclusions of the committee were, that the last proposal was the only method having prospects of commercial success, and the installation was therefore contracted for, and is now under partial operation.

The digest of the estimates is as follows :—

	Tramway.	Benzine Omnibuses.	Electric Trolley Omnibuses.
Total cost	£62,530	£23,581	£25,050
Do. per mile of route ...	£9,260	£3,500	£3,700
Expenses per car-mile including repairs, renewals, depreciation, and 4 per cent. interest... ...	7·730d.	9·45d.	5·13d.

Digitized by Google

The benzine omnibuses and the electric vehicles were of about the same capacity; the tramcars would have given considerably more accommodation.

The prices of labour for both construction and operation are lower in Germany than in England. The tariff is correspondingly low.

The Mülhausen line is interesting, not only from being the longest yet undertaken upon this system, but also from the severity of the gradients. The corporation decided that the Public Gardens line should precede the zone route, and that the brake tests should be such that the braking of either axle independently should be sufficient to hold the car on the steepest gradient, and also to bring it to a standstill in the shortest possible time. Also, that these tests should be carried out in winter. The road is of macadam saturated with tar by a new German process, which attains a smoothness almost equal to that of asphalte, and much resembles "tarmac."

The car is steered and driven on the front axle, the wheels of which are rubber tyred, the rear axle having steel tyres; both axles are supplied with mechanical brakes, and the front axle with an electric brake. The car accelerates and maintains speed on the gradient of 1 in 12 without any trouble; the single forward brake gear is sufficient for holding the car, but the braking of the tyred wheels on the rear axle has required modification. During a recent visit paid to this installation by Mr. Bertram Douglas Fox, chief electrical assistant to the author's firm, the car was put through all the tests required by the authorities, and the performances were satisfactory. This section of the line is now opened for traffic. On some of the lines in Germany, goods transportation is being carried on upon the same lines as a passenger business without any inconvenience, the former being handled by trains of cars hauled by a double-ender electric locomotive, the cars being provided with a coupling and steering device which compels them to follow the exact course taken by the locomotive.

At the figures of working expense estimated by the Mülhausen committee, the author contends that such a system could pay its way in this country with the smallest revenue earned by any tramway in England, even allowing for the higher rate of wages here than in Germany.

This was the only electric trolley omnibus system described in the Paper, and no actual costs were given of lines actually running.

The author next proceeded, by an analysis of the accounts of the 71 municipal tramways already referred to, "to show the degree to which this great system of urban transportation has overstepped the limits of commercial soundness," and "by the selection of typical cases to show the principles which should govern the design of a transportation system from a commercial point of view." We give this part of the Paper below in a slightly abbreviated form :—

1. *The Rentability of the Tramway System.*

The capital expenditure on the 71 installations has been		£27,213,674
The gross income in 1907 was		6,361,860
The operating expenses		3,833,370
Leaving net income		2,528,160
The deductions made were :—		
Interest	801,906	
Sinking fund	641,074	
Income tax	39,012	
Depreciation	528,733	
Sundries	176,753	
		2,187,478
Net surplus		+ 340,682

The gross surplus was contributed by 36 towns, which was disposed of as follows :—

Carried forward	56,854
Reserve	52,932
Reduction of rates	335,194
	£444,980

Deficits were shown by 20 towns, the remainder coming out even.

In the following table the deductions from income, &c., are reduced to percentages of income and of capital expenditure :—

	Percentage	
	Net Income.	Capital Expenditure.
Interest	31·90	2·945
Sinking Fund	25·55	2·355
Income Tax	1·55	0·143
Depreciation	20·60	1·945
Sundries	7·00	0·650
Total	86·60	8·038

The surplus from the 36 towns was disposed of as follows :—

	Percentage	
	Net Income.	Capital Expenditure.
Carried forward	2·25	0·209
Reserve	2·10	0·95
Reduction of rates	13·27	1·230

The entire surplus available from the aggregate of the undertakings is thus seen to be about 1½ per cent. on the cost of construction. On 30 of the tramways, representing over 500 miles of single track, no allowance for depreciation is made. If this is reckoned at £400 per mile, or £200,000 per annum, the surplus would be reduced to about 0·75 per cent. on the capital expenditure. The total amount set aside for depreciation by those towns which make any appropriation under this heading averages £336 per mile of single track. If the whole of the 2,071 miles included in the list were provided for at £400 per mile, there would be a deficit in place of a surplus.

A surplus of a bare 1½ per cent. on such a system of tramways as that of Great Britain cannot be claimed as a lucrative result. It may be contended that the system as a whole would have been equally unremunerative if it had been built up and run by private companies. Without discussing so wide a question, it is plain that this form of municipal exploitation is greatly on the increase and enters into the programme of politicians of socialistic tendency. More than twenty years ago the suggestion of free urban transportation was put forward in the Colonies. The London County Council is engaged in a collossal municipalisation scheme, in which the experiment of a maximum capital expenditure is combined with a minimum passenger fare, and at the present rate of progress, it cannot be many years before the general public will be compelled to take something more than an academic interest in it.

Occasionally some journalist raises a warning note, but the whole subject arouses as little concern in the persons most concerned as does the National Debt. Whether municipal indebtedness is to be reduced or not does not trouble the average ratepayer. The working classes need cheap travel. Whether the means adopted will relieve or increase the rates affects them far less than the question of the facilities themselves, and the working classes elect the town council. It is only when the increase of rates reaches the point of driving the manufacturer, possibly their own employer, to a cheaper district, that it begins to touch their personal interests. If corporations want to borrow and the working classes support them, the Board of Trade will sanction the loan, even when the rates are already as high as can be tolerated.

At a town council meeting a short while since, when the tramway project was under discussion, the chairman said, with a fine satire, that its commercial prospects were a "Limerick," to which the ratepayers must apply the last line. The authorisation was, however, applied for and duly granted.

As to the present outlook, it may be asked whether there is any probability of the tramway system clearing off its debt. If we take the system in its entirety we can see no possible chance. From the Board of Trade returns lately issued we see that the loan capital has risen in the last 30 years from 4 to 64 millions. Amortisation has, of course, gone on, but the borrowers keep on borrowing more than they pay off. If, on the other hand, we take the seven largest and best paying tramways, in which it would appear as if construction had approached its limit, we find that at the present rate of amortisation the debt would be cleared in about 26 years, and these tramways would then have about a million pounds of surplus at their disposal. They could either apply it to reduce the average passenger fare of a 1d. to ½d., or they could reduce rates by an amount equal to about 5s. per head of population served. Probably, however, long before then, they will have decided to replace the overhead system by an electrical conduit or in some other way will have enlarged instead of reduced their loan capital.

2. *Rentability as Compared with Size.*—Although as a rule big tramways pay and small ones do not, there are remarkable exceptions of both kinds. Fourteen cities of populations varying

Digitized by Google

from 100,000 to 232,000 either show a deficit or no surplus. The aggregate amount of deficit being £7,225.

On the other hand, the smallest town boasting an electric tramway—Maidstone, with 13,000 inhabitants—shows a surplus. Ayr, a town of 33,000, pays fixed charges, puts aside a depreciation fund, and carries over a surplus of £1,000.

The following table illustrates this point:—

Population.	Number of Tramways.	Number providing depreciation fund.	Number showing surplus.	Number showing deficit.	Number with even balance.
up to 20,000	2	0	1	1	0
20 to 40,000	7	4	4	3	0
40 to 60,000	9	3	0	8	1
60 to 80,000	6	3	2	1	3
80 to 100,000	4	2	2	0	2
100 to 150,000	12	3	3	2	7
150 to 200,000	8	5	3	1	4
200 to 300,000	6	5	6	0	0
300 to 500,000	5	5	5	0	0
500 to 1,000,000	3	2	3	0	0

It will be noticed that prosperity is at its lowest ebb in the case of tramways serving from 40 to 60,000 and only becomes invariable in the case of those serving over 200,000. In tramways serving 40 to 60,000 there is a sudden increase of proportion of double track mileage. It would seem, therefore, that at this point of population tramway construction has been too heavily saddled with the cost of double track. It is not to be inferred that all the tramways which show no depreciation fund, or even which show a deficit, are permanent failures from a commercial standpoint. Some of them are of recent date, and may have a good future before them. On the other hand, it would appear from the foregoing table that about half the tramways provide no depreciation fund, and about one-quarter come out with a deficit.

3. *Capital Expenditure per Mile.*—The total capital expenditure, in the 55 tramways having combined generating stations, ranges from £10,630 to £37,210 per mile of route, and from £7,516 to £20,728 per mile of single track, the two extreme cases being Halifax and West Ham respectively.

In the 16 towns having separate generating stations for lighting and tramway purposes, the cost ranges from £17,750 to £46,300 per mile of route and from £10,888 to £23,514 per mile of single track, the two extreme cases being Preston and Portsmouth respectively.

The cause of this great variation is mainly in the cost of permanent way and widenings, and expenses incidental to obtaining authorisation. The rolling stock, overhead equipment and generating stations are fairly uniform in cost. With regard to permanent way, however, in the first place there is generally a horse-car track to be bought up, and a new track laid down, which involves numerous and often heavy incidental expenses. Some towns are overburdened with length of permanent way needed to reach the population, others with peculiarly heavy cost of the permanent way itself. At Halifax, for instance, 37 miles of route were needed to serve 178,000 population, or about twice the average proportion; the cost per mile of track is comparatively low, the average number of rides quite normal, and the receipts per car-mile exceptionally high, but the undertaking appears to be handicapped by its length. At Wigan, the ratio of length to population is four times the average, and the cost of track per mile nearly twice the average; in such circumstances the immense deficit of over £16,600 is not to be wondered at.

Comparing the capital expenditure of British with that of American and Continental tramways we find that the British undertakings are as much burdened by excessive first cost as is the railway system. An estimate is given in Mr. Ashe's book which he regards as a fair average of the cost of an American tramway, and which works out at about £6,300 per mile of route, or about one-third that of the average, and not much more than one-half the lowest figure in British tramways. The estimate made by the town council of Mülhausen, Germany, previously referred to, for a tramway was also between one-half and one-third of the average of British tramways. In America, a lower first cost is combined with a higher tariff. The question of first cost should obviously be studied in connection with the possible tariff, as to which more is said later.

4. *Route-Length Factor.*—This factor is the length in miles of route per 1,000 of population. Its normal length depends upon the extent to which the population is scattered or condensed, and whether the routes are parallel or radial. The factors given in the table are only approximate averages for British tramways, in an element of design which is necessarily extremely variable. They apply only to the more usual form of towns and their suburbs, but not to inter-urban lines or towns with detached suburbs. In these cases the factor is higher. As a general rule, the factor is in inverse proportion to the size of the town, because, as the population increases, it becomes denser, principally on account of the increased value of land.

In the tramways considered, this factor ranges from 0·033 to 0·4. Only one case having over 0·2 mile per 1,000 is remunerative. On the other hand, the low ratios are not either as a rule remunerative. Lincoln, for instance, with 52,500 people and a factor of 0·033, comes out with a deficit. The riding habit factor is only 27, thus the tramway can only by a flower of speech be said to "serve" its population.

The average of the 55 towns in the first list is 0·107, and in the second list 0·098 mile of route for 1,000 population.

APPROXIMATE ROUTE-LENGTH FACTORS FOR URBAN TRAMWAYS IN ENGLAND.

Population.	Route Factor.	Population.	Route Factor.
20,000 ...	0·180 to 0·220	120,000 ...	0·113 to 0·139
40,000 ...	0·162 to 0·198	140,000 ...	0·105 to 0·129
60,000 ...	0·147 to 0·179	160,000 ...	0·099 to 0·121
80,000 ...	0·134 to 0·170	180,000 ...	0·094 to 0·115
100,000 ...	0·123 to 0·150	200,000 ...	0·090 to 0·110

As a mere memoriser, and subject to amendment according to circumstances, the factor may be taken as ranging from 0·2 in the smallest to 0·1 in the largest town.

In America the riding habit being much greater, the towns are also better served.

5. *Density of Traffic or Riding Habit.*—Very approximately, the density of the traffic, expressed in average journeys per head of population per annum, varies with the size of the city. When the route mileage is proportioned to the population, the variation of riding habit becomes still more closely proportional to the size of the city than in the statistics. In the 71 cases cited, the riding habit varies from 27 at Lincoln, a town of 55,000, to 213 at Glasgow with 1,000,000. Lincoln, however, has only 0·033 per mile per 1,000 people, and as they do not live in sky-scraper buildings they cannot be said to be served.

Maidstone again, already referred to, with a population of only 13,000 people carries it 91 times per annum, forming a very favourable exception in high density of travel with small population. Kirkcaldy, Southport, and Wigan are also remarkable cases of the same kind.

It may be thought a hazardous thing to give any rule for estimating the density of travel in a city where results vary as greatly as they do. It is, however, less hazardous to form some kind of rule based upon study of statistics, than to make a mere guess, as is too often done. The following table is only intended as a rough approximation, subject to more accurate estimation from the study of the particular case, and provided the system is of dimensions, and so laid out, as to be truly described as "serving" the population:—

Population.	Riding Habit.	Population.	Riding Habit.
20,000 ...	50	120,000 ...	89
40,000 ...	65	140,000 ...	93
60,000 ...	74	160,000 ...	95
80,000 ...	81	180,000 ...	97½
100,000 ...	86	200,000 ...	100

and for each 100,000 more, add 12½ rides per head per annum.

The curve corresponding with the above figures will, in the main, agree with the statistics of British corporation-owned tramways, and will generally be found rather under than over the actual riding habit.

6. *Income per Car Mile.*—In the cases analysed, the income per car mile ranges from 5·8d. to 13·9d. The average of all is about 10½d. per car mile. Low receipts may be caused by a too frequent time interval between cars, by too low a tariff, by too low a speed, or other ground of unpopularity in the cars themselves.

In America, the income per car mile of 18 electric railways given in a table by Mr. Ashe ranges from 4·61d. to 14·25d. per car mile, the lowest income where no deficit is made being 4·65d.

7. *Working Expenses per Car Mile.*—In the British tramways analysed, the variation is from 4·6d. to 8·59d., the average being 6·25d. High costs are generally found with a high route length factor. Probably the upkeep of track is chiefly responsible, but administration expenses borne by a light business in proportion to size are also contributory. The lowest working expenses are those of Kilmarnock, which is, however, not thereby saved from a deficit. The riding habit factor is here fairly high as compared with the route-length factor, and the tariff is normal. With this size of town, something abnormal is required, either in the riding habit or the tariff to make the undertaking pay.

8. *Interest and Sinking Fund per Car Mile.*—In the British tramways these figures range from 1·93d. to 5·30d., very approxi-

Digitized by Google

mately in direct proportion to the capital expenditure per mile. The average of the whole is about 3·6d. Probably about half this burden is due to permanent way.

9. *Average Fare Charged per Mile.*—This ranges in the British tramways from 0·36d. to 1·0d., and the great variation does not appear to correspond with variation in cost of construction and operation. In the case of electric lighting companies, the cost to the consumer is always made to vary with the cost of production, but in traction companies there are many curious anomalies. The Parliamentary fare on railways is 1d. per mile, and there is no reason why a tramway should be victimised by a tariff of about one-third of that amount. In some cases it is possible to operate a tramway on a much lower tariff than 1d. per mile, which is, of course, then recommendable, as, for instance, at Hull, where, with a tariff of 0·36d. per mile, the Corporation is able to put aside a fairly good depreciation fund, and to carry over a surplus amounting to 4 per cent. of the capital expenditure. Maidstone, on the other hand, the smallest remunerative tramway of the United Kingdom, levies the standard tariff of 1d. per mile, and could not have earned a profit at a lower tariff. It has, however, more than double the normal riding habit factor.

When one comes to the long list of tramways which declare a deficit, and compares it with the fares charged per mile, the results are startling. Probably London, with its deficit of over £25,000 per annum would be the most surprising of any. Unfortunately, in the statistics, London does not give its average passenger fare. There can be no doubt, however, that it is extremely low. Taking the other 19 tramways, which together have a deficit of £48,000 per annum, we find that with three exceptions these tramways levy a fare under 1d. per mile, carrying passengers at rates varying from 57 per cent. under normal fare and upwards. The financial result, supposing these tramways all levied a fare of 1d. per mile instead of their present fare, would represent a surplus of about £70,000 in place of a deficit. It will at once be replied that the travelling public would not submit to a fare of 1d. per mile in these cases. Naturally they would not. When once the passenger has been allowed to travel partly at the expense of the ratepayer, he will not surrender his privilege. It is practically impossible to raise fares when once they have been established at an unremunerative figure. This does not, however, contradict the fact that, combining actual deficit with possible surplus, a sum of over £100,000 per annum is given away to the general travelling public in place of finding its way to the coffers of the undertakings.

If municipalisation of tramways is subject to ordinary business principles, the practice of letting the public travel partly at the expense of the ratepayer is to be condemned as vicious. If, on the other hand, commercial principles are not to be held to govern this form of exploitation, consistency should demand that the full programme of the Socialistic propaganda should fix the goal of municipalisation as that of free urban transportation. There is at present a lack of programme.

10. *Power Consumption, Cost per Car Mile, and Cost per Unit of Power.*—The variations in the statistics are very much greater than would appear natural to the diversity of local conditions. As to power consumption per car mile, this varies from 0·88 unit in the case of Keighley to 2·08 units at Burnley. This variation is more normal than that of the cost, and depends upon the weight of cars, density of traffic, and gradients to be overcome. The maximum gradients in the two above-mentioned towns are 1 in 25 and 1 in 9·8 respectively.

The cost per B.O.T. unit varies from 0·32d. at Leeds to 2·14d. at Lowestoft. The variation depends on the kind of engines used, the cost of fuel, and the output of the plant. The output in the two cases cited above are 13 million and 350,000 units respectively. It should not, however, be taken as a necessary drawback of a small installation that the power cost should be anything like as high as it often is. Even with steam plants, there are cases of comparatively small installations where the cost per unit is under 1d.

The internal combustion engine has been proved to be capable, when judiciously installed, and efficiently managed, of placing the small power station almost on a level as to fuel cost with the large station. Gas engines with suction or producer gas as fuel have under certain conditions been proved extremely economical. Unfortunately, however, there are many cases of very unfavourable results which are all easily to be accounted for either from bad design or management, but which have much interfered with the progress of this form of generator. There certainly ought, however, to be no tramway needing to pay 2d. per unit for power.

With regard to the total cost per car mile for power, this varies from 0·37d. at Glasgow to 3·032d. at Burnley. From various causes, therefore, many of them quite avoidable, it costs eight times as much to drive a car in one place in England than in another. Certainly a surprising fact, even when all allowances are made.

11. *Average Speed per Hour.*—The gain in speed through the introduction of mechanical traction in great thoroughfares is not as much as the passenger imagines.

During the tests made with the London Electrobus, speed curves were obtained of several omnibuses plying on the same route, between Liverpool Street and Victoria. The variations were considerable with the same class of vehicle, but the average of a number of tests was as follows :—

	Average speed between termini. Miles per hour.	Highest average speed between any two cross streets. Miles per hour.
Horse Omnibus	5·30	8·75
Electric Omnibus	6·25	10·00
Petrol Omnibus	6·50	11·00

The police regulations limit the maximum speed to 12 miles per hour. Taking the above averages, a passenger travelling half a mile would save about a minute as between the horse 'bus and the electric, or about a quarter of a minute as between the electric and the petrol 'bus, but the latter saving is mostly a matter of chance.

The statistics of average speed per hour of tramways are misleading. They sometimes mean schedule speed and sometimes the actual average, that is to say, the total car miles per annum divided by the total car hours per annum. Thus the minimum is Northampton, 5·6 miles per hour, which is the true average, while the maximum is 10 miles per hour at Hull. This latter, however, is only the schedule speed, the true average being 7·1 miles per hour. Northampton might, as far as speed is concerned, continue to operate by horse traction.

The London County Council also under "Average speed" appears to give the schedule speed of 8½ miles per hour, whereas it works out at 7 miles per hour.

ANALYSIS OF 55 TRAMWAY INSTALLATIONS HAVING COMBINED GENERATING STATIONS FOR TRACTION AND LIGHTING PURPOSES.

Population served	7,045,285

DISCUSSION.

Mr. P. S. SHEARDOWN (Dublin United Tramways, Ltd.) said that "railless traction" would seem to offer a possibility at cheap capital cost of opening up suburban or country traffic in connection with existing tramway systems. It was remarkable, he said, how little the application of electricity to tramway systems had added to the route mileage throughout the United Kingdom. This was due to the fact that, owing to the heavy capital expenditure, the standard method of construction did not pay except in a fairly densely populated district, where circumstances compelled people to move from one locality to another. In the first part, dealing with the comparison of the operation of the standard form of electric tramways with the petrol and electric accumulator omnibus, the conclusion the author arrived at seemed to be that a case might be made out for the latter form of traction, provided receipts could be guaranteed at 1s. per mile, which it was well known was almost impossible to obtain, except in areas of very dense population. The financial position of the petrol motor-'bus generally seemed to be a disastrous one, and although the author appeared to make out a better case for the electrobus, it must be realised that his estimates were formed on a very small service of these vehicles. The electrobus being undoubtedly more in favour with the general public, it resulted in its taking better receipts per car-mile, but this advantage would disappear as more of them were put on the streets. It must also be remembered that the surface of the London streets was remarkably smooth compared with that of provincial towns and suburban roads. Running on a smooth surface naturally reduced the traction effort required; it also saved wear on tyres and saved the deterioration in the accumulator due to excessive vibration, so that the figures obtained in London with both petrol and electric omnibuses could really only be applied to London, as the conditions elsewhere varied considerably. With regard to the figures given by the author, showing that on the whole the large amount of money sunk in electric tramways had proved to be an unprofitable investment, it must be remembered that most of these figures related to municipal tramways which, it was now generally recognised, were not run with the sole object of making profits, vote-catching being apparently much more what was sought after. Mr. Sheardown expressed his regret that more details had not been given with respect to "railless traction," but undoubtedly, although not yet tried in this country, he said, it would appear to have the elements of advantage for feeling around for further traffic with the smallest possible capital outlay, provided that a supply of electricity could be obtained without building a power station, and that facilities were given for carrying current at high pressure on the poles. In this connection it would appear as if the single-phase traction motor might be suitable for adoption, owing to the much greater facility with which alternating current could be distributed without loss. In ascertaining whether a traffic would be remunerative, it would probably pay for the first few years to put up with a fairly heavy cost for energy per car-mile due to transmission loss, &c., which could be subsequently rectified by investing additional capital when the possibility of the line with regard to traffic had been ascertained. He was of the opinion that a very much cheaper form of overhead construction might be employed than that which was standard in towns at the present time, as if the wire could be carried on short brackets close to the poles by developing the flexibility of the trolley arm, the weight of the poles and the cost of erecting them could be very materially reduced, and bare copper wire was an article which could be always turned into money. The great saving with regard to capital expenditure was that the costly permanent way was not required, for it must be realised that a tramway company not only provided an iron road to take up the wear of its own traffic, but also a substantial road which was kept up at the tramways' expense, but was used and worn out by the ordinary road traffic. The third portion of the author's paper, the speaker continued, was full of interesting statistics, which, owing to the fact that nearly all the possible tramway systems had been electrified, could not be made very much practical use of. Certain remarks made by the author would seem to indicate that an authorised electric tramway system ran practically without competition, but although this apparently often was so, it was not so in practice, as it was always in competition with the natural means of locomotion given to man. On the surface it would always appear that an increased revenue per car-mile could be obtained by running fewer cars, but this meant reducing the interval between the service, with the result that people only going short distances walked instead of waiting for the car. In the same way, if one reduced the distance people were carried for a given sum, no benefit would ensue, as people would walk the distance that had been taken off the original fare, or, in other cases, were offended, and walked the whole distance.

Mr. P. C. COWAN (Engineer, Irish Local Government Board) asked whether the figure of 5·13d. per car-mile, as mentioned in the case of railless traction, included the cost of repair to the road. This, he said, was the turning-point on which this system of railless traction seemed to hinge. What would be the wear on the road with this system as compared with the ordinary road traffic, and who was going to pay for the upkeep of the road? He further mentioned that there was an admirable road from the terminus of the Dublin tramway system at Donnybrook to Bray with a first-class surface on which the enterprising Dublin Tramway Co. might make some interesting experiments.

Mr. RYDER thought the system was very suitable for the development of traffic in many parts of Ireland, but he thought that the first experiment should be made on level roads. He did not quite agree with Mr. Sheardown's remarks that the wear on rubber tyres on the London roads would likely to be less than the wear which would take place on rougher paving; he thought that the continual stopping and starting in the crowded London traffic must be very severe on the tyres.

Professor WIMPRESS said the Paper was most interesting, although the last part was more suitable for the section of the Association dealing with statistics. It was very difficult to obtain practical results in many cases from statistics. In the case of Lincoln mentioned, he thought that the reason of non-success there was the fact that the old part of the town was built on what was practically the side of a hill, and it was very difficult to connect it with the rest of the town.

Mr. LONG also referred to the matter of what was likely to be the additional road wear with the railless form of traction. He said that he had seen some such form of traction working round the London Exhibition, and the havoc it caused to the roads there was deplorable.

Mr. FOX, in reply, stated that he thought the answer to the question that had been raised of the wear to the road was that the weight per axle could be kept low and need not exceed a ton and a quarter per axle. This was possible, due to the fact of the electric motors and gear weighing much less than the machinery required for a petrol or accumulator 'bus. In reply to Mr. Cowan's question whether 5·13d. included the cost of road repair, he said that £100 per mile per annum had been put aside and was included in this figure. With reference to Mr. Long's remarks *re* railless traction in the White City, what he referred to was a Renard train which was running round the Exhibition. This, with regard to weight, was very different to what he contemplated, and moreover it must be remembered that the paths in the Exhibition had been very quickly made, and must only be regarded as temporary.

Steam Turbine Design.

THE following is an abstract of a Paper on "Experiments on Rotating Discs," contributed by Messrs. J. BROWN, F.R.S., and MAURICE F. FITZGERALD :—

The authors begin by referring to the difficulty of the mathematical analysis of the elastic deformation, under centrifugal stress, of rapidly revolving discs, particularly when formed with a central hole, surrounded by a thick boss, gradually reduced outwards to a thin edge by an arbitrary curve, and mention the investigations of Mr. Chree and Mr. F. Purser of the cases of cylinders and ellipsoids. The authors' experiments are described as made for the purpose of finding out whether approximate formulæ, such as have been given for cases in practice in such works as that of Stodola on steam turbines, are sufficiently nearly correct for practical purposes. Two discs, made of red rubber weighing 72 lb. per cubic foot, were tested. The discs were both 12 in. external diameter. One was solid, ½ in. thick at edge, 2 in. at the centre, its surfaces being two flat cones. The other was ⅝ in. thick at edge, in its centre was a hole 1½ in. diameter, surrounded by a boss, with flat ends 2½ in. diameter, and 3 in. thick, the surfaces between the edges of the boss and disc being shaped to hollow hyperbolic curves. The discs were suspended from the end of the shaft of a small motor, placed with its axis vertical, and circles drawn on the faces, previously painted white, while spinning. Photographs being taken of the discs while spinning and when at rest, the strains at different radii were found by comparison of the photographs, and plotted as curves, shown by lantern slides. The results were compared with those of approximate formulæ. In the case of the solid disc the difference between the speeds causing a given strain as calculated and as observed, amounts to about 20 per cent. and may, considering the imperfect elasticity of india-rubber, be considered a fair enough approximation; but in the case of the other disc, though the formula gives a tolerably fair idea of the shape of the curve of strains, its error as to the actual magnitude of the speed causing a given strain is so great, being near 400 per cent., as to lead to the conclusion that the formula could not be trusted for practical purposes.

Physics and Chemistry.

Helium and Radium.— SIR JAMES DEWAR'S Paper on "The Amount of Helium Evolved from Radium," attracted considerable attention. He announced that he had discovered that Crookes' radiometer could be used as a very sensitive pressure gauge. He connected a radiometer with a bulb filled with charcoal, and immersed in liquid air. The great exhaustion

Digitized by Google

thereby produced sufficed to stop the radiometer even when illuminated by an arc lamp. On attaching a tube containing dry perchlorate of potash, and evolving pure oxygen from it, it was found that the radiometer begins to work at one 50-millionth of an atmosphere, equivalent to the vapour pressure of mercury at −23° C. The Macleod gauge only reads down to double that pressure. He applied the new method to determine the amount of helium evolved from 70 milligrammes of radium bromide, and found the amount to be 0·37 cubic millimetres per gramme of radium per diem, which strikingly agrees with Rutherford's theoretical value of 0·3 cubic m.m. He asked Mr. Strutt if he still thought all helium was evolved by diffusion from rocks. The HON. R. J. STRUTT maintained that the earth would not be capable of retaining helium in its atmosphere, and that only an underground source could account for the amount of helium present in the atmosphere. In reply, SIR JAMES DEWAR mentioned that Bryan had shown that gases of the atomic weight of helium are heavy enough to be retained by the earth.

The Inductance of Two Parallel Wires.—The following is a Paper on this subject, contributed by Dr. J. W. NICHOLSON :—When direct and return currents flow in two wires of great length, and the alternation is not rapid, the effective self-induction L per unit length of the system may be calculated readily by simple integration.

If the wires have radii (a, b) and permeabilities (μ, ν), and if c be the distance between their axes,

$$L = 2\log\frac{c^2}{ab} + \frac{1}{2}(\mu + \nu)$$

But this formula is generally of little practical use when the frequency of alternation is several thousands per second. Such frequencies are of constant use in practical work, where pairs of long wire leads are continually employed, whose self-induction must be small. A knowledge of the effective self-induction of such leads is therefore very desirable. The general case presents considerable mathematical difficulty, but the solutions given below appear to include most cases of practical utility.

The mode of proof depends chiefly upon a transformation of a series of Bessel functions of type K_n finite at infinity, to another series similarly related with respect to a new origin. The disturbances caused by one wire in the vector potential due to the other may be summed to a high order of accuracy. From a knowledge of the vector potential, the total current in each wire, and thus the self-induction, may be deduced.

The result for wires not too close together is

$$L = 2\log\frac{c^2}{ab} + \frac{2\mu}{x}\cdot\frac{\mathrm{ber}\,x\,\mathrm{ber}'\,x + \mathrm{bei}\,x\,\mathrm{bei}'\,x}{(\mathrm{ber}'\,x)^2 + (\mathrm{bei}'\,x)^2} + \frac{2\nu}{y}\cdot\frac{\mathrm{ber}\,y\,\mathrm{ber}'\,y + \mathrm{bei}\,y\,\mathrm{bei}'\,y}{(\mathrm{ber}'\,y)^2 + (\mathrm{bei}'\,y)^2},$$

where (μ, ν) are the permeabilities of the wires, (σ, σ') their resistivities.

$$x = 2a\sqrt{\frac{\pi\mu n}{\sigma}},\quad y = 2b\sqrt{\frac{\pi\nu n}{\sigma'}}$$

and ber x, bei x are the functions introduced by Lord Kelvin, and afterwards tabulated. Their main properties are well known to mathematical electricians.

Measurement of Large Inductances containing Iron.—Sir OLIVER LODGE, F.R.S., and Mr. BENJAMIN DAVIES' Paper on this subject was identical with one which has already been published in the *Journal* of the Institution of Electrical Engineers. The following is a brief abstract :—We have had occasion lately to measure large inductances, up to and above 100 henries, with core consisting of subdivided iron in a nearly close circuit, as used for certain telegraphic purposes with very weak currents. Since the inductance may vary rapidly with strength of current, it is necessary in any measurement to imitate the conditions of practice, and to determine the inductance as a function of current under those conditions. To this end we have designed a maximum-amplitude galvanometer, consisting of a well-damped coil moving *dead beat* in a strong magnetic field, and attached to a mirror so that the amplitude of its excursion can be observed. It can subsequently be calibrated by means of a steady current giving the same deflexion. The inductance to be measured is connected up in series with this galvanometer, and with a specially designed alternator of small power and known frequency $p/2\pi$, giving a sinuous or simply harmonic current. A switch allows the inductance to be suddenly replaced by a non-inductive adjustable resistance R′; and when under these conditions the same oscillation is produced in both cases, then the self-induction is equal to that equivalent resistance divided by the frequency constant; or $L = R'/p$. The strength of the current involved in this measurement is known by imitating the deflexion with a known steady current; and the main measurement consists simply in observing the deflexion caused by the sine-alternator, at a measured frequency, either with the inductance, or with the adjustable non-inductive resistance, indiscriminately. It is to be understood that the ohmic resistance of the wire wound on the self-induction is low. If not, a correction must be applied for that, which is easily done, since $\sqrt{(R^2 + p^2L^2)} = R'$.

The following empirical expression is found able to give the self-induction of a nearly closed magnetic circuit excited only by very weak currents, since for such currents it is found to be practically constant.

$$L = \frac{kn^a}{(G+g)^b}$$

where n is the number of turns, G the width of the air-gap in millimetres, and the other quantities are constants to be determined by experiment: though a will naturally be nearly 2. In an actual case of a nearly closed magnetic circuit the following values were found :—

$a = 1{\cdot}99$; $b = 0{\cdot}47$;
$k = 18$ henries; and $g = 0{\cdot}1$ millimetre.

The result of this method of measurement applied to inductance coils of this type shows : (1) that measurements based on a determination of the square root of mean square of current would serve fairly well for low magnetising forces; (2) that the self-inductance of such coils is for weak currents nearly independent of frequency, or say for all frequencies up to about 20 per second, when the magnetising force does not exceed 0·04 c. g. s.; (3) that the self-inductance of a nearly closed magnetic circuit is a definite and dependable function of the width of the air-gap for moderate currents and frequencies.

On the Extension of Optical Ideas to General Electromagnetic Fields.—Dr. E. T. WHITTAKER's Paper with this title showed that the resolution of a beam of light into two components polarised in planes at right angles to each other, leads to an expression of the state of the luminiferous ether in terms of two potential functions, one of which corresponds to each of the polarised beams. It was then shown that the state of the ether can be expressed in terms of these two potential functions, not only in the case in which the disturbance consists simply of luminous or electromagnetic waves, but also in the more complicated cases when electrostatic charges and voltaic currents are present in the field. It thus appears that the ether is a medium with two essential qualities, which are both scalar (like the pressure and temperature of a gas); and the various vectors in terms of which the electromagnetic field is usually specified (*e.g.*, the electric force and magnetic induction), are merely derived from the variation of these two qualities in space and time.

The Inactive Gases of the Atmosphere.—Sir WILLIAM RAMSAY, F.R.S., gave evidence to show that there was no gas lighter than helium in the atmosphere, unless we suppose that that lighter gas can penetrate glass, as helium does, to a slight extent. Professor RUTHERFORD attacked Sir W. Ramsay's method of producing neon by the action of radium emanation upon water. He said that even 1/15th of a c.c. of air would show the neon spectrum. To this Sir W. Ramsay replied that every care had been taken to keep air out of the apparatus. Professor W. N. HARTLEY doubted that lithium was as rare as Sir Wm. Ramsay thought, in comparison with sodium and potassium. Lithium was found in limestones, in dust, in the Bessemer flame, in ordinary pipeclay, tobacco pipes, and a great variety of siliceous minerals, such as the Dublin granites; in Donegal kyanite, which contains 98 per cent. of aluminium silicate; and in asbestos. It was found in dust which fell from the clouds, in volcanic dust, in soot, in flue-dust from chemical works, and in that from copper smelting and refining works. Sir JAMES DEWAR read a communication from Dr. Kamerlingh Onnes on the liquefaction of helium.

The Rapid Electro-analytical Separation of Metals.—Mr. HENRY J. S. SAND gave a demonstration of a process of electro-analysis, in which the principle of very vigorous stirring of the electrolyte has been combined with that of keeping the potential of the cathode under control by means of an auxiliary electrode. It has thus been possible very largely to extend the scope of electro-analytical methods. The following metals have hitherto been studied. First the metals of the silver and copper groups and zinc, *i.e.*, silver, mercury, copper, bismuth, lead, cadmium, and zinc. These metals have all been deposited singly, separated from each other and also separated when all present in the same solution. In the last-named case the quantity of each metal taken varied between 0·10 and 0·15 gramme, and the time for the deposition of each between about ten and fifteen minutes. Secondly, new methods have been elaborated for the determination and separation from each other of antimony and tin. A considerable number of determinations have been carried out in which the metals taken in varying ratios weighed together approximately one gramme. The time for the deposition of the antimony was usually about twenty minutes, that for the tin about eighty minutes. Lastly, the possibility has been examined of securing a purely electro-analytical method for the analysis of an alloy consisting of copper, antimony, lead, and tin, and all the separations required for such an analysis have at the present time been carried out.

Secondary Radiation.—Prof. J. A. MACCLELLAND read a Paper on "Secondary Radiation," dealing with its various types. In the case of the secondary radiation due to β-particles, care must be taken to distinguish between β-particles reflected or "scattered" in the direction of reflection, and truly secondary β-rays liberated by a kind of trigger action upon the atoms of the metal. The latter proceeded impartially in all directions. As regards the secondary radiation of β-particles due to γ-rays,

Digitized by Google

it is found that the number of β-particles liberated per atom of the exposed substance varies as to atomic weight. This law applies, at all events, until the higher atomic weights are reached, when the number increases more rapidly, owing probably to the greater instability of the atoms. The work of Bragg and Hackett makes it probable that γ-rays are not ether pulses, but doublets made up of opposite ions, or opposite electrons. In the matter of γ-rays liberated by γ-rays, and the secondary rays liberated by ultra-violet light, there was still much obscurity.

Prof. E. RUTHERFORD gave credit to Prof. MacClelland for having discovered the relation between atomic weight and secondary radiation. He asked whether Prof. MacClelland would describe a particle as "scattered" when it returned upon its own path, and what criterion he relied upon to distinguish primary from secondary radiation. (Prof. MACCLELLAND: Yes. The criterion is chiefly to velocity.) The Hon. R. J. STRUTT confessed himself as being somewhat bewildered by the complexity of secondary radiation. He could not readily conceive how the velocity of secondary rays could be greater than that of the primary. Prof. MACLENNAN said the ionisation method, which was mostly used in these experiments, was a kind of omnibus method, and did not give very precise indications concerning velocity. The magnetic field should be more extensively used for this purpose. In reply, Prof. MACCLELLAND said he hoped the work indicated by Prof. MacLennan would soon be undertaken. The velocity of secondary radiation was less, not greater, than that of the primary. It was evidently due to some "trigger" action within the atom.

The Scintillations of Zinc Sulphide.—Prof. E. RUTHERFORD read a Paper describing his determination of the luminous efficiency of these scintillations. The α-particles, or helium atoms, which produced the effect in the spinthariscope, did so by dissociating the molecules of the ZnS. The recombination of these probably produced the light. He had compared the light on a zinc sulphide screen with a 2-c.p. lamp, and found the screen to have about 0·01 c.p. Knowing the number of α-particles per second and their speed, their total energy could be calculated. On the other hand, the mechanical equivalent of the light emitted was also calculable from Stephan's law. The calculation was very rough, but it indicated a very high efficiency of the light, as high, perhaps, as 80 per cent. In reply to a question, Prof. Rutherford said the spectrum of the scintillations was continuous, and mostly in the blue.

The Boiling Point of Radium Emanation.—Discussing a Paper by T. Royds on the grating spectrum of the radium emanation, Sir JAMES DEWAR said that the boiling point of the emanation could be arrived at by two different methods. By the periodic system, a boiling point of 244° C. abs. (−26° C.) was indicated. By Trouton's law of molecular latent heat, they obtained the value 250° C. abs., showing a fair agreement. Prof. RUTHERFORD said the boiling point must be much lower, as he found the emanation evaporating right down to the temperature of liquid air. Prof. TROUTON said that might be due to slight differences of temperature in various parts of the apparatus.

Rate of Evolution of Heat by Pitchblende.—Mr. HORACE H. POOLE described a determination of this made in the following manner:—A spherical vacuum jacketed vessel with a narrow neck is filled with powdered and carefully dried pitchblende. The neck is filled with cotton-wool and rendered water-tight with sheet rubber, and the whole is buried in ice. The difference of temperature between the layer of pitchblende in contact with the bottom of the vessel and the ice is measured by a sensitive thermo-couple. After about a fortnight this temperature becomes steady, when the heat leakage across the walls of the vessel is equal to the heat generated by the pitchblende. This leakage depends solely on the vessel and on the difference of temperature between inner and outer walls, which is measured by the thermo-couple. The thermal conductance of the vessel is found by substituting water for the pitchblende and determining its rate of cooling. Hence the heat leakage is known, and, knowing the amount of pitchblende present, the heat evolution per gram is found. The thermo-couple is calibrated by placing one junction in finely broken ice and the other in a mixture of broken ice and water, which can be subjected to a known pressure. The deflection caused by the resulting small change of temperature is noted, and hence sensitiveness of couple is found. Using 560·7 grs. of pitchblende in an atmosphere of nitrogen, the temperature finally steadied at 0·0092° C. As the thermal conductance of vessel is 5·8 calories per hour per degree difference of temperature between inside and outside, this corresponds to a heat leakage of 0·053 calorie per hour. Hence heat evolution per gram of pitchblende is 0·000094 calorie per hour. This is about twice the quantity estimated from the known amount of radium present.

Constitution of the Electric Spark.—Mr. T. ROYDS described "Further Experiments on the Constitution of the Electric Spark." The results obtained by photographing on a rapidly-moving photographic film the spectrum of the ordinary oscillatory spark with small self-induction have already been communicated to the Royal Society. The method has now been applied to study the spark when the self-induction of the circuit is gradually increased. On account of the feebleness of the light in these cases it has been found necessary to remove the prisms, photographing directly the image of the slit, in order to avoid the loss of light due to dispersion by the prism. It is still possible under these conditions to differentiate by their character the streamers in the metallic vapour from those in the air. Condensers, whose capacity amounted to about one-third of a microfarad, were charged from a large Wimshurst machine, and the spark of 8 mms. length passed between metal electrodes. Self-inductances ranging in value up to 0·026 henries could be inserted in the circuit. The velocity of the photographic film was about 100 metres per second.

The commencement of the spark is marked by a sudden and almost instantaneous luminosity of the air, showing on the photographs as a narrow vertical line. The duration of the luminosity is not appreciably affected even when the period of the circuit reaches a value of about 2×10^{-4} secs. This initial air discharge does not start quite simultaneously at all parts of the spark length. It is followed by another type of streamers through the air in which the duration is comparable with the interval between the oscillations; in some cases the oscillation is divided into more than one air streamer. After the initial air discharge has passed, the light from the spark is chiefly due to the metallic vapour which is produced. The moment of vaporisation of the metal is simultaneous with the passage of the initial air discharge. The first streamer in the metallic vapour often reaches to the centre of the spark. The slope of this streamer gives the velocity with which the vapour first produced is moving along the line joining the two electrodes. The luminosity of the metallic vapour afterwards consists of streamers starting from the electrodes. At the instantaneously positive electrode the luminosity of the streamers is of longer duration than at the negative; the streamers are not so numerous nor so distinct. There is not, however, the marked difference in the intensity of the streamers at the instantaneously-positive and negative electrodes which was noticed in a previous Paper on the spark with small self-induction. It is again found, however, that at the commencement of the spark, vapour is produced at both the positive and negative electrodes. Dark spaces at the electrodes separate the oscillations of the circuit and serve to measure the period of the oscillations.

The measurements of the photographs show that the velocity of the metallic vapour first produced is smaller in the spark with self-induction than in the ordinary spark. In the case of mercury, for example, the velocity becomes 620 metres per second; the velocities found in the ordinary spark are 1,150 and 940 metres per second for two different types of spectral lines. This is more probably due to a reduced temperature rather than to the supposition that the quantity of metal vaporised is not sufficient in the former case to produce the difference of pressure required to make the velocity of diffusion attain its maximum value. The introduction of self-induction brings out the "arc" lines of the metal. The evidence now obtained that the arc lines are due to, or accompanied by, a lower temperature confirms Lockyer's supposition which forms the basis of his researches on star temperatures.

When the self-inductance of the spark is increased, it is seen that during a single oscillation several streamers start from the electrodes; they are more distinct with magnesium than with lead, bismuth, or mercury. The streamers are too numerous and close together to make useful the supposition that they are due to harmonic overtones of the fundamental period of the circuit. The streamers are found to recur at definite intervals after the commencement of each oscillation of the spark, though they are not invariably present in every oscillation; generally not more than about ten appear in a single complete oscillation. These intervals are the same in different photographs of the spark under the same conditions, but the individual streamers are not always reproduced in the same oscillation in different photographs.

Position of the South Pole.—Mr. L. C. BERNACCHI presented a contribution on the results of some physical observations taken on the National Antarctic Expedition by the *Discovery*, 1902-1904, in lat. 77° 50′ 45″ S., long. 160° 44′ 30″ E. The magnetic and other physical observations conducted on the shore close to the ship extended over a period of nearly two years. The *Discovery's* "winter quarters" were to the south-east of the south magnetic pole, the mean absolute declination being about 152° E. From the photographic records by the Eschenhagen magnetometers the general character of the regular diurnal variation of declination is clearly shown, the movement being five or six times as large as that at Kew; even during the months when the sun is continuously below the horizon, the diurnal range remains large—at least double that at Greenwich at midsummer. The seasonal change in the type of the diurnal variation is very small. In temperate climates generally the changes of declination during the day are conspicuously larger and more rapid than during the night. At the "winter quarters" there was no such marked difference. The horizontal force at the "winter quarters" was about a third of that at Kew, but the range of the diurnal inequality about 50 per cent. greater than at Kew. The type also varies very little with the seasons, and is totally different to that at temperate stations.

Vector diagrams have been made for the "winter quarters" for the whole year, and for the seasons midwinter (May to July), equinox (March, April, September, October), and midsummer

Digitized by Google

(November-January). The differences between these diagrams and the vector diagrams for Kew and Falmouth are remarkable. There is much less asymmetry than in England, the direction of motion is anti-clockwise, and there is very little difference in type for the different seasons. The most striking peculiarity in the diurnal inequality in all the elements is the large size of the fundamental or 24-hour Fourier "wave" as compared to the harmonics of shorter period. In order to determine the position of the south magnetic pole by means of all the declination observations taken at the "winter quarters," sledge journeys, and at sea, the results have been plotted (by Captain L. W. P. Chetwynd, R.N.) and the direction of the magnetic meridian as indicated by the observations extended towards the magnetic pole. These lines of direction intersect within a space triangular in form. The radius of the circle inscribed in the triangle measures about thirty-eight geographical miles, and the centre of the circle indicates the probable position of the pole, and is in lat. 72° 50′ S., long. 156° 20′ E. All the inclination results were plotted on a chart and lines of equal inclination drawn, from which the probable position of the pole is indicated to be in lat. 72° 52′ S., long. 156° 30′ E. The agreement between this position and that determined by the declination results is remarkable, and may be considered as corroboration of the results.

A report on the magnetic observations at the Falmouth Observatory was presented by the Committee, consisting of Sir W. H. Preece (*Chairman*), Dr. R. T. Glazebrook (*Secretary*), Prof. W. G. Adams, Dr. Chree, Captain Creak, Mr. W. L. Fox, Sir A. W. Rücker, and Prof. Schuster. The mean values of the magnetic elements for the year 1907 were:—Declination, 18° 0′4 W. Horizontal force, 0·18799 C.G.S. Vertical force, 0·43330 C.G.S. Inclination, 66° 32′·7 N. The observatory at Eskdalemuir has only commenced work during the current year, so that comparative results are not yet available, while the disturbances due to electric traction in the neighbourhood of London have a natural tendency to increase.

The Photometric Standard of the National Physical Laboratory.—Dr. R. T. GLAZEBROOK, F.R.S. (Director of the National Physical Laboratory), contributed a Paper upon this standard. It had been shown by Mr. Paterson in 1904 that the relation between the candle power of the 10 c.p. Vernon Harcourt Pentane Standard at the laboratory and the humidity of the air is given by the equation, Candle-power $=10+0{\cdot}066(10-e)$, where e is the amount of moisture present measured in litres per cubic metre of air, so that the standard condition is when 10 litres of moisture are present and the lamp has its nominal value 10 c.p. In Mr. Paterson's experiments the quantity e was measured (in nearly all cases) by an ordinary wet and dry bulb thermometer, and the observations reduced by the usual formula.

At the Reichsanstalt an Assmann ventilating hygrometer is employed for the purpose, and the International Commission on Photometry recommended at Zürich the use of some ventilating hygrometer. This has led to a comparison of the two kinds of hygrometer in the still air of the photometer room, with the result that it has been shown that the ordinary wet and dry bulb instrument gives results some 20 per cent. higher than the Assmann. The standard humidity, then, in the previous experiments, when measured by the Assmann, was 8 litres (not 10) per cubic metre, and Mr. Paterson's formula becomes: Candle-power $=10+0{\cdot}066(8-e)$.

The present Paper discussed the question whether, since a change has to be made, it is desirable to retain the standard humidity at 10 litres, measured by the Assmann, and in consequence to change the light value, at any given humidity, of the National Physical Laboratory standard lamp by about 1·3 per cent., or whether it is preferable to retain the light value and change the standard humidity. The latter alternative is recommended. In this the gas referees concur. The changes which are involved, in consequence, in the value of the ratio of the Pentane candle to the Hefner candle, and to the Bougie decimals are considered, and it is shown that, adopting as the basis of comparison the results arrived at by the Commission at Zürich, and altering the standard value of the Pentane candle to 8 litres humidity, the Pentane candle and the Bougie decimale become practically equal, and each is equal to nine-tenths of the Hefner.

The practical consequences of this were first pointed out to the author in a letter from the Bureau of Standards of America, and he hopes that they will be thought sufficient to lead the International Gas Commission to consider the question of the change at their next session.

Manufacture of Parabolic Reflectors.—Mr. SHERARD COWPER-COLES described his method for the production of true metallic surfaces for parabolic reflectors, in which the mirrors are deposited electrolytically on a carefully ground glass mould. The preparation of this mould is a long and costly operation, but when once prepared the reflecting surface can be reproduced in metal any number of times at a fraction of the cost, thus enabling mirrors of a true parabolic curve to be manufactured at a very cheap rate. The mould is coated with a thin film of silver on the convex side by a chemical process, and mounted in a metallic ring, which makes contact with the silver film, and is then suspended with the convex side downwards on a spindle, placed above an electrolytic cell for depositing copper. The spindle is rotated at 5 to 10 revolutions per minute, whilst the copper is being deposited on the silver coating until a sufficient thickness has been obtained to give the necessary rigidity. The glass mould and copper deposit is then placed in warm water and gradually heated until the expansion of the copper causes it to leave the glass mould. The mirror thus produced has a surface as highly polished as the glass, and of exactly the same curvature. A silver-faced mirror thus produced would tarnish and be scratched too readily for practical purposes, so it has to be faced with some harder untarnishable metal or alloy. The metals usually employed for this purpose are platinum, palladium, or an alloy of silver and cadmium, which are deposited in a bright form. The process was also described in ELECTRICAL ENGINEERING, Vol. III., p. 550, in which some additional information will be found.

Reference is made to other Papers on electrochemical subjects under "Electrometallurgy and Electrochemistry," on p. 435.

TRAMWAY STRIKES IN AUSTRALIA AND NEW ZEALAND

IN the course of an article published on Friday from the *Times* Australian correspondent upon labour troubles in Australia, the following particulars are given of the recent tramway strike in Sydney:—Sydney's tramways are a Government enterprise under the control of the Railway Commissioners. The system is overhead electric; the drivers are mainly married men, the conductors more usually young bachelors, often sons of country farmers who prefer a less arduous life in the city. Both classes had grievances. The drivers complained that they must run their open-fronted cars through all weathers, and that none but the strongest could get through a winter without the doctor's help. The conductors were irritated beyond measure at a system which tested their honesty by sending plain-clothes detectives as ordinary passengers, and comparing in the central office the tickets they obtained with the record of those the conductors ought to have issued—this being supposed to detect cases in which a conductor might dishonestly reissue a used ticket and pocket the fare. Theoretically the system is a fair one, however much prejudice may be created against it by calling it espionage. In practice it has many defects; and not long ago a conductor who had been dismissed for reissuing used tickets was lucky enough to obtain convincing evidence of his honesty, and was reinstated accordingly. This threw grave doubt on the efficacy of the system in actual practice; and when a second conductor (Croucher by name), with an admittedly admirable record for good conduct during many years' employment, was dismissed on a similar charge, on the evidence of two young constables who had quite recently abandoned farm labour to join the police, there was great and sustained indignation throughout the tramway service. Mass meetings demanded Croucher's reinstatement and the abolition of the system. The new Chief Commissioner was sympathetic. He retried Croucher's case, but upheld the dismissal (one cannot but remark in passing that, when the evidence was published in full, it did seem as if Croucher might well have been given the benefit of the doubt). He admitted the weaknesses of the espionage system, inviting suggestions for its reform, promised that no more dismissals should occur meanwhile. But "Croucher" had become the tramwaymen's Shibboleth; his final dismissal was the signal for a strike. Of a sudden Sydney found itself forced into using legs that had almost atrophied. For two days—two fine days—the situation was accepted almost jocularly; and then came the rain. The rain is not over yet—but the strike is. The reason, the *Times'* correspondent states, is that the railway employees refused to join the movement.

A similar difference of opinion took place early in the summer between the employees of the Auckland Electric Tramways Co. and the company itself, a strike being ordered by the Auckland Electric Tramways Industrial Union of Workers. The reason in this case was the dismissal of a conductor, without any reason being assigned. There was an absolute deadlock, both sides refusing to give way. The matter therefore went to the arbitration of a special Conciliation Board, which has now issued its award, entirely in favour of the men. The recommendations of the Board are:—(1) That Conductor Herdson be reinstated in his position. (2) That the general manager shall give a written guarantee that in future any employee being dismissed from the service shall be given a valid reason for his dismissal. (3) That any employee being sent to the head office for an alleged fault shall see all reports made against him, and have the right to call evidence on his behalf. (4) That any inspector proved guilty of making mis-statements of false reports against employees shall be instantly dismissed. (5) Seeing that Mr. Lysaght's (the traffic manager) questionable methods were the real cause of the strike of November, 1906, and that the recent harassing of motormen and conductors by ticket inspectors has been in obedience to his instructions, he shall be removed from direct contact with the men. (6) The Board directs that the foregoing recommendations shall take effect from the first day of September, 1908, and shall continue in force until the 31st day of August, 1910. The result is viewed with some consternation by employers in New Zealand, and may be taken as an indication of the growing power of the Labour Party there.

ELECTRIC VERSUS STEAM TRACTION AND RAILWAY PROGRESS

IN a recent issue of the *Bulletin de l'Institut Electrotechnique Montefiore*, was published an essay presented by M. Pavlitzky to the Fourth Russian Electrotechnical Congress, held at Kieff, dealing very fully with the comparative value of electric and steam traction on main line railways, under modern conditions. M. Pavlitzky postulates that:—"The principal aim of modern railway practice is to diminish the cost of transport per ton mile, and at the same time to increase the carrying capacity. Only electric traction permits the attainment of that aim, thanks to its unlimited power, and to its facile adaptation to the variable conditions, and the increasing necessities of traffic." He follows up this proposition with the remark: "We must note that the discussion of the economics of electric traction should be made independently of the existing organisation and working of existing railways."

Pointing out that the conditions under which it is generally admitted that electric traction is superior to steam traction are those presented by short lines requiring a frequent service and a considerable number of trains, and where running times must be reduced to a minimum, the author proceeds to recount the usual objections to the wider application of electric traction, most of which he considers are fully met by the general admission of railway and electrical engineers that it is purely a commercial question, resolving itself into a justification of the heavy capital expenditure required. This justification requires a complete study of the whole extent and consequences of electrical working as contrasted with those of steam working, and especially the recognition of the most important and essential quality of electric traction, viz., its power of increasing the carrying capacity of a railway, and reducing the cost per ton mile of the traffic on it.

The propositions to be proved may be stated thus:—(1) To show that the characteristics of the electric locomotive meet the requirements of railway managements; and (2) to examine the general and special conditions applying to the movement of heavy trains, which must be satisfied by the electric locomotive.

The modern requirements and tendencies of railway working are best shown by the recent developments in the United States, which possesses more than a third of the total railway mileage of the world, and where the rate of development has been 50 per cent. greater than in Europe, with, as yet, no signs of falling off. But in both Europe and America the tendency is to increase the power of the steam locomotive, with the object of getting from it the greatest possible number of ton miles. To this end the locomotive must be powerful, require little attention, and infrequent repairs or stoppages. These requirements are conflicting, because power depends upon steaming capacity, and increased steaming capacity necessarily entails more labour, more repairs, and more stoppages. Contrasting the different methods by which European and American engineers have sought to give the steam locomotive the power and other qualities needed to deal with the increased intensity of traffic, it is evident to the author that the limit to the capacity of the steam locomotive is already in sight, and that to provide for the necessary continuous development of railway traffic it is essential that the substitution of electric traction should be considered.

The tendency to increase the speed and weight of trains, and to utilise the track and rolling stock to the greatest advantage, shows itself in all branches of railway construction, and it appears that the limits of steam traction are already in view, and are closely approached on some of the important main lines, both in America and Europe. We may add that the financial results of railway operation in the United Kingdom, at least, indicate that existing methods do not satisfactorily meet modern conditions, and that railway managements, when they have found the limits of the advantages of amalgamations and similar nostrums now fashionable, will have to turn their attention to more fundamental improvements. Our author infers that the development of traffic requirements in the directions of higher speed, greater utilisation of the track, heavier paying loads, and cheaper transport will persist, and that as steam traction has reached its limit, it must give way to something superior. The alternative is to suppose that railway transport has reached finality, and that no improvement is possible.

As the ultimate limit to the economical capacity of a railway is prescribed by the power and other qualities of the locomotive, a general comparison between the peculiarities of steam and electric locomotives defines the character and extent of the improvements which are potentially attainable by the substitution of electric for steam traction.

This sentence gives the key of the author's argument, and, as applied to railways upon which the density of traffic is already great, or on which a greater amount of traffic cannot be economically handled by steam without great expense in the doubling or improvement of lines, the argument is difficult to refute.

He shows in considerable detail that while the power of a steam locomotive is limited, in effect, by the steaming capacity of its boiler, and that the limits are already attained, the power of an electric locomotive is only limited by that of the station supplying it, and that instead of providing many different types of locomotives to suit different services, and more or less difficult sections of line, the electric locomotive lends itself to standardisation and to the application of power as and when it is needed by the adaptation of the multiple unit system. The efficiency of the electric locomotive considered as a motor is greater than that of a steam locomotive; it utilises the whole of its weight, or even some of the live-load weight, for adhesion; it can be built with no longer rigid wheel base than that of the train vehicles; the tractive effort distributed over a larger number of wheels, and applied by a steady rotary motion, instead of one subject to the effect of reciprocating masses, is greater per ton of axle load, and applied with less severe stresses upon the track and structures than that due to a steam locomotive; the power used in propelling the locomotive itself is very little in excess of that required by a similar weight of ordinary vehicles, whilst the steam locomotive requires from two to three times the pull per ton of total weight.

Considering these advantages as to the power available and better running qualities, the author suggests that in the construction of new railways, especially in mountainous districts, considerable economy will be possible by the adoption of shorter routes, with more severe gradient and curves than are advisable on a steam line, and that existing railways on which gradients and curves limit the capacity or increase the working expenses unduly, may receive a fresh lease of life by electrification, instead of by the much more costly process of improvement of alignment and profile.

It is admitted that weight for weight the steam locomotive is cheaper than the electric locomotive, but such a basis of comparison is evidently erroneous; power for power the positions are reversed, and when the annual carrying capacity and mileage, the small cost of labour, repairs, and maintenance are taken into account, it is claimed that a much smaller capital expenditure in locomotives is needed for a given traffic capacity on a given line. The author goes so far as to suggest that to provide for a very heavy traffic the whole electrical equipment of a railway may cost less than the provision of steam locomotives, but wisely remarks that it is idle to give general figures when every case must be worked out by itself.

Coming to the crux of the question—capital cost—the author believes that in many cases of new lines the total cost of construction and equipment may be less, or at least not exceed that for steam traction. Towards this he points out that the track may cost less, that expenditure on engine sheds and shops will be less, that less rolling stock will be needed, because it will be better utilised, and that there will be many other details in which economy will be found possible. But there will be many cases in which the first cost will retard electrification, though it will not lead to its ultimate rejection. In the electrification of existing lines the capital expenditure involved is more serious, and whether for new or existing lines the question in every case is whether electric traction will offer advantages which will cover the interest and sinking fund charges upon the first cost. The author has no hesitation in giving an affirmative answer, providing that on an existing line the electrification permits of a required increase of traffic with which steam traction cannot deal. He points to the statistics obtained from, *e.g.*, the Valtellina line, as confirming his optimism in respect to working cost and increased carrying capacity, and to the considerable amount of railway electrification which has occurred, and is still in progress, as showing that responsible authorities agree with him.

The conclusions arrived at are not materially different to those which have influenced the electrification of urban and other passenger railways, where the traffic demands could not be economically met by steam traction; the fresh aspect put forward is that similar considerations call for the electrification of lines carrying heavy traffic and suffering from congestion or otherwise worked up to their economical limit. The method of arriving at this conclusion from a consideration of the fundamental properties and differences of the steam and the electric locomotives is novel, ingenious, and convincing, but, like most arguments of the kind, its application to any particular case resolves itself into a quantitative question—How much expendi-

Digitized by Google

ture, how much increased traffic capacity, how much saving in working expenses? The hardened railway manager will also ask: How much extra traffic shall I get? even if the answers to the other questions are satisfactory, and that may be the hardest question of all to answer in a definite way. The answer available is by analogy, and the records of railway traffic supply a sufficient basis, if properly considered. Increased facilities, reduced rates, greater expedition, induce goods traffic just as surely as they do passenger traffic. Congestion of goods and mineral traffic is frequent on most of our heavy lines; there have been numerous instances during the last few years of railway companies being unable to handle the traffic offered them, and the comparatively poor dividend results reaped from the manufacturing boom of the last three years is largely accounted for by the extraordinary expenditure needed to work systems much beyond their economical capacity. A great deal of capital has been spent in providing relief lines, doubling lines, enlarging sorting yards, as well as in providing locomotives and rolling stock, which would have been better spent in increasing the effective use of the existing lines and material, had the means been at hand. It is in this direction, as our author points out, that electric traction promises improvement, financial as well as technical, sufficient to justify the capital expenditure.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

THERE was not very much in connection with electrochemistry at the meeting of the British Association in Dublin. Professor Armstrong, however, introduced a discussion upon the Ionic Theory. As is his custom, he condemned it and physical chemists in general. He started by saying that the assumption of independent ions in solution had not been experimentally proved, and he did not believe that hydrochloric acid, for example, was dissociated in aqueous solution into H cations and Cl anions, but that in contra-distinction to dissociation there is an association between the water molecules and hydrochloric acid. He would therefore write hydrochloric acid in solution:—

$$H_2O\langle^{Cl}_{H},$$

and he considers that when an E.M.F. acts, be it ever so little, it is sufficient to break down this unstable molecular complex, and then the chlorine will be carried to the one pole and hydrogen to the other. He likewise affirmed that there was no proof and no probability that water itself was to a certain extent dissociated into H and OH ions. The physical chemist argues that there are a certain number of such ions even in pure water. Armstrong says, "get your water pure and it will be an absolute non-conductor." But the hydrolysis of salts is under modern theories attributed to this very dissociation. It cannot, however, be stated that his arguments, although interesting, were very convincing. In any case, the dissociation theory has proved an extremely useful ground for research, and physical chemists have undoubtedly very much enlarged our knowledge of the internal structure of things. The word "ion," however, always arouses the fury of Prof. Armstrong; as he once said, someone remarked, "let there be ions, and there were ions all over the place." We all know that all acids contain hydrogen, and very often in referring to the strength of an acid one refers to the number of hydrogen ions in a solution. But Armstrong says there are no ions, but that all acids are produced by the union of something with water, but as water contains oxygen, therefore the original name for oxygen—which means acid producer—is correct. In the discussion which followed, Sir Oliver Lodge remarked that physicists had no objection to imagining hydration of ions. They also had no particular objection to the formula for hydrochloric acid in solution which had been put upon the board, only they would rather imagine in place of one molecule of water the union of a very large number, which would then cause the hydrochloric acid to be in such a state of instability that the least E.M.F. would break down the complex and allow the current to pass in. Armstrong was getting nearer to the physical chemist than he had ever done before. Sir William Ramsay remarked that as all mention of electrons had been omitted it was hardly possible to discuss the question because chemists looked upon ions as being a collection of electrons. Prof. Armstrong considered that this only added to the confusion. Other speakers wanted to know how Prof. Armstrong explained conduction in fusion salts, but on this point discreet silence was maintained.

The only other papers of interest to electrochemists were two upon "Rapid Electro-deposition of Metals for Analytical Purposes." One was by Dr. H. S. Sand, which he illustrated by means of apparatus, showing how copper can be deposited out within the space of a very few minutes. The other one was by Dr. F. M. Perkin, and Mr. W. Hughes and Dr. Perkin showed two new forms of apparatus for the same purpose as that of Dr. Sand. In the one case a rotating cathode in the form of an elongated thimble is used, a platinum gauze cylinder acting as anode; and in the other case a spiral anode of platinum is employed, and a gauze cylinder serves as cathode. It was also shown how this apparatus could be used for depositions by means of the graded potentials when an auxiliary electrode is employed to maintain a constant potential.

The problem of the utilisation of peat in places such as Ireland, where it is found in such enormous quantities, is one of primary importance. The difficulties, however, have always been, how can the peat be used in such a manner that no large expenditure shall be required to prepare it? Of course, air-dried peat can be burned as fuel for domestic purposes, but only a small portion of it can thus be employed, and, furthermore, there are certain disadvantages in its employment for this purpose. For many years past, therefore, attempts have been made to utilise the energy stored up in peat for power purposes. The difficulty met with, however, has been the large percentage of moisture which even air-dried peat contains. "Peat and its Utilisation" was the subject of a Paper read by Capt. H. R. Sankey before the British Association. This Paper was abstracted in last week's ELECTRICAL ENGINEERING, page 393, and the discussion on it will be found on p. 396 of the same issue. A Paper was also read by Dr. Woltereck in section B. It is hoped in the near future to employ peat for the manufacture of gas for power purposes, and also for the manufacture of calcium carbide, and then to employ the calcium carbide for making cyanamide. Experiments which have been conducted with a Mond generating plant show that one metric ton of peat containing from 42 to 47 per cent. of moisture will produce 2,800 cubic meters of gas, which contains from 36 to 39 per cent. of combustible products; and the gas yielded from turf containing from 65 to 70 per cent. of moisture contains 28·6 per cent. by volume of combustible gases. Such gas can very well be employed for driving gas engines. Taking the better quality peat, it is found that 2·4 cubic meters of the gas will generate one effective horse-power; therefore, one ton would generate 1,150 h.p. Taking 1,000 h.p. as the amount actually obtained, one ton of this peat would fix from 16 to 20 kg. of atmospheric nitrogen in the form of nitric acid, or 50 kg. in the form of cyanamide. Now, over and above the gas power which can be obtained, there is an extremely useful by-product produced at the same time, namely, ammonia. The amount of ammonia obtained depends upon the quantity of nitrogen in the original peat. For example, from a sample which contained 1·05 per cent. of nitrogen, 40 kg. of ammonium sulphate were obtained by burning one ton of it in a generator. In Stockton, peat containing 2·85 per cent. of nitrogen was employed, and 110 kg. of ammonium sulphate were produced from the ton. Good dividends are being earned by some Swedish works, and if it can be done, there seems no reason why it should not be a success in Ireland.

In *Electrochemical and Electrometallurgical Industry* of September there is a useful article upon the "Electro-deposition of Nickel," by Dr. E. F. Kern and Mr. F. G. Fabian. This article is really a *résumé* of methods employed in the electroplating of nickel. The authors have investigated the methods, and have arrived at the following conclusion. The most generally employed electrolyte is a solution of nickel-ammonium sulphate, which may be neutral or slightly acidified with a feeble acid, such as boric, phosphoric, benzoic, acetic, tannic, tartaric or citric acid; it may also contain alkali salts of these acids. The addition of the acid is for the purpose of dissolving basic salts of nickel which are caused by oxidation at the anode. An excess of acid, however, causes evolution of hydrogen, which produces spongy or non-adherent deposits. Electrolytes containing nickel-ammonium phosphate are used to less extent than those containing nickel-ammonium sulphate. In exceptional cases electrolytes containing nickel chloride and nickel-potassium cyanide have been employed. The presence of boric acid in nickel electrolytes not only keeps the solution clear, but also causes the formation of a smoother and less brittle deposit than when none is present. The amount used varies between 1·5 to 30 grams of boric acid per 100 c.c. solution. Nickel deposits formed from nickel-ammonium sulphate electrolytes are harder, smoother and more durable than those obtained from chloride electrolytes. The addition of 5 to 10 grams of sodium chloride per 100 c.c. of nickel-ammonium sulphate electrolyte reduces the E.M.F., and also causes the deposit to form more reguline, more adherent, and tougher, and the anode to dissolve more uniformly. Pure nickel anodes are less readily dissolved than those which contain iron, copper, tin, &c., unless the electrolyte contains chloride. Rolled sheet anodes are less readily dissolved, and require a higher E.M.F. than cast anodes. Rough cast anodes require less E.M.F. and are more uniformly dissolved than smooth, polished cast anodes, or sheet nickel anodes. The solution which is used for recovering nickel from nickel-copper mattes or alloys is

Digitized by Google

either dilute sulphuric acid or dilute hydrochloric acid. The copper in either solution is reduced below 1 per cent. by electrolysis, and finally completely removed chemically. The purified solution is rendered alkaline, filtered to remove precipitates, and the nickel recovered by electrolysis in suitable cells, using a lead anode for the sulphate solution, and a graphite one for the chloride solutions. There is a difference of opinion as to the cause of reguline, adherent deposits of nickel; some electrometallurgists claim that the most satisfactory deposits are from alkaline electrolytes, whereas others say that the electrolyte must be acid. The general opinion, however, is that non-adherent deposits are due to the electrolyte being too acid, the temperature of the electrolyte being too low, or else the cathode is not clean. Pulverulent deposits are due to too high a current density, too high an E.M.F., and too acid an electrolyte. Conditions which favour solid adherent deposits of nickel are slightly acid electrolyte, to prevent formation of basic salts, pure electrolyte, gas-free electrolyte, temperature between 40° and 65° C.; constant current density; low E.M.F.; efficient circulation; clean cathode; and concentrated electrolyte. The tendency of nickel deposits to curl is greatest with high-current density, said to be due to formation of nickel hydride, which is the result of greater liberation of hydrogen with high current density and high E.M.F. Messrs. Kern & Fabian consider that "the conductivity of an electrolyte varies directly as the weight of salt in solution, and the more concentrated the electrolyte the more satisfactory the deposit."

THE PACIFIC CABLE

THE Chairman of the Pacific Cable Board, in his annual report upon the accounts of that undertaking for the year to March 31st, 1908, states that the Board have to deplore the loss of their Chairman, Sir Spencer Walpole, K.C.B., who died very suddenly on July 7th, 1907. He was the first occupant of the post, having been nominated to it by the Pacific Cable Act, 1901; and the ability and zeal with which he discharged his functions were very fully appreciated by his colleagues, and earned for him their high regard. Since the close of the year, the Board have sustained another severe loss in the death of Mr. C. H. Reynolds, C.I.E., who, from the commencement of the enterprise, has served them most faithfully and efficiently in the capacity of general manager. He died on May 21st, 1908, at Lisbon, where, though already suffering severely from the malady which caused his death, he had gone to represent the Board at the International Telegraph Conference.

The financial results of the year 1907–8 are set forth in the following statement:—

RECEIPTS.

	£	s.	d.
Traffic Receipts	113,548	18	1
Less Atlantic Companies' charge for conveying date and time, and for delivering duplicate copies in London and other large centres in United Kingdom	3,911	13	0
Interest on deposits	522	17	3
Deficiency recoverable in the following proportions:—			
United Kingdom	17,322	18	4
Canada	17,322	18	4
Australia	20,787	10	0
New Zealand	6,929	3	4
	£172,522	12	4

EXPENDITURE.

	£	s.	d.
Fifth Annuity payment	77,544	18	0
Head Office (salaries and expenses)	4,345	9	1
Head Office (advertising, canvassing, engineers' fees, royalties, and cost of remitting money home)	1,596	12	7
Stations (salaries and expenses)	38,764	16	1
Ship (salaries and expenses)	16,759	12	11
Provident fund	1,511	3	8
Renewal account	32,000	0	0
	£172,522	12	4

As compared with 1906–7, there was a falling off of £2,852 15s. 2d. in the gross traffic receipts: but of this the greater part (from £1,800 to £2,000) is apparent only, not real, the accounts for 1906-7 having included the receipts at Southport for 13 months, while those for 1907-8 include only 12 months' takings. As regards the remainder of the decline, it may be observed that the message revenue of 1906-7 was enhanced by the increase of business resulting from various circumstances, viz., the earthquake at San Francisco, interruptions to the Eastern Extension Company's cables, and the general prosperity of trade; whereas during 1907-8, the cable has had to contend against adverse conditions of trade resulting from the panic in America of last summer and autumn, and other unfavourable influences. The only set off against these was an increase of traffic which resulted from a week's interruption of the Eastern Extension Company's Cocos Island cable in August last, and taking all the circumstances of the two years into account, it may be considered satisfactory that the revenue of the cable has been maintained so well as it has been.

On the expenditure side of the account there has been an increase, as compared with 1906-7, of £4,082 13s. Of this, £2,027 16s. was due to the insurance which it was decided during the year to effect on the Board's cable ship; but under the terms of the contract with the underwriters a considerable rebate is claimable for periods during which the vessel remains in harbour, and on this account, nearly one-half of the premium will probably be eventually recovered. The remainder of the increase is attributable to various causes, such as the normal growth of incremental salaries, the increase in the charges for officers going on leave now that the staff has had some years of service in the tropics, and the fact that the accounts include the cost for a whole year, instead of for nine months only, of the new offices opened in Sydney and Melbourne in 1906.

Exclusive of the annuity payment of £77,544 18s. covering interest and sinking fund on the capital advanced by the National Debt Commissioners, the expenditure on the maintenance and working of the cable during the year, including the sum of £32,000 carried to the renewal account, and the sum of £1,511 3s. 8d. contributed to the provident fund, amounted to £94,977 14s. 4d., or £15,182 8s. less than the net revenue earned by the cable. The annuity to the National Debt Commissioners absorbs this surplus, and £62,362 10s. in addition, which has to be made good by the several Governments associated in the enterprise.

The total contributions to the renewal fund, including interest, amounted on March 31st last to £198,836 12s. 11d., £12,500 of this sum being held in spare cable. The amount of £177,691 12s. 11d. is invested in home and colonial securities as shown in Statement VI., while a balance of £8,645 was in hand, and has since been invested. All interest earned on the investments is added annually to the fund, and is not treated as part of the revenue of the year.

The Board's forecast of its probable revenue and expenditure during the year 1908-9, as submitted to their Lordships on December 20th last, is as follows:—Traffic revenue, £108,000; estimated deficit, £69,566, making a total of £177,566. The expenditure is estimated as follows:—Sixth annuity, £77,545; renewal fund, £31,000; working expenses, £69,021.

The land line services in Australia and New Zealand, in connection with the cable, have been generally well maintained by the Governments concerned. The Atlantic companies have afforded uninterrupted cable communication throughout the year, and a rapid and efficient service. In Canada, the lines of the Canadian Pacific Railway, both in Vancouver Island and elsewhere, suffered considerable interruption, first from bush fires and unusual electrical disturbances in July, August, and September, and later from severe storms in November and December. In the latter month, a gale occurred in Vancouver Island which is said to have been the worst on record in that region, and caused an interruption of over 70 hours, all the wires having been thrown down. In August, moreover, the traffic, more especially that to the States, was considerably disorganised by reason of the strike of telegraph operators in Chicago, and the sympathy it excited amongst those employed by the Canadian Pacific Railway.

The health of the staff has been satisfactory throughout the year, and the service rendered by them has continued to be maintained on the high level of efficiency and zeal which has characterised it in previous years. Throughout the year the cable has worked without interruption, and no repairs have been called for. The buildings, electrical apparatus, and plant, at all stations, have been maintained in good order. No damage has occurred to the repairing vessel "Iris," and the discipline and efficiency of the ship's company have continued to be thoroughly satisfactory. The wharf and shed, which the New Zealand Government undertook to provide for her use at Auckland, were completed by January of this year, and permanent moorings for the vessel are now in course of being supplied. These works will be of much benefit to the safety of the ship, and to the comfort and convenience of her crew, and the Board feel greatly indebted to the New Zealand Government for the liberality with which they have given this valuable assistance.

The number of messages transmitted during the year was 105,189, against 97,818 for the previous year, and the number of words, 1,250,345, against 1,128,662. Both these figures represent the highest point yet reached by the Board.

In addition, a very considerable Intercolonial traffic is carried between Australia, New Zealand, and the Fijis, keeping the Southern sections of the cable fully occupied during business hours.

The Paris Strike.—In connection with the strike of the employees at the electricity works a short time back (ELECTRICAL ENGINEERING, August 13th, p. 238), M. Pataud (Secretary of the Electricians' Union) has been sued by three music-hall artistes for damages on the ground that they were unable to give their performances. A nominal fine of 8fr. in each case was ordered.

THE NATIONAL TELEPHONE EMPLOYÉS' GRIEVANCES

THE National Society of Telephone Employés issued the following statement to the *Daily Telegraph* and other papers on Monday:—

A very grave crisis has arisen in the telephone world, owing to the action of the National Telephone Company (Ltd.), in dismissing thousands of their employés on the ground of reduction of staff.

As is now well known, the Government have entered into an agreement with the National Telephone Company for the purchase of the latter's undertaking, or such of it as the Post Office require, at the expiration of the company's licence in 1911. When the agreement was ratified by the House of Commons in August, 1905, Lord Stanley (now the Earl of Derby), the then Postmaster-General, assured the House that all efficient servants of the company should be taken into Government employ under certain conditions. As things are at present proceeding, there will be but few of the company's staff left in 1911 to take advantage of this promise.

The reason for these increasing and wholesale dismissals is fairly obvious. The company, owing to its life being limited to three more years, will not expend capital upon which it cannot see the return of the outlay and a margin of profit by the end of that period. Hence orders for telephones are being refused by the hundred, and men who should be employed in the construction of lines are thrown idle, to swell the already overcrowded labour market. The responsibility for this state of things lies with the Government, who, by their action in ending the existence of the National Telephone Company, are stopping the legitimate growth of the telephone industry. That a serious state of affairs is created is obvious from the fact that already the number of men discharged approaches 1,000, and it is stated on the authority of high officials of the company that 6,000 men will be discharged prior to 1911.

Men who have had seven, ten, and up to twenty-five years' service with the Telephone Company have received their discharge notices, and after having spent the best years of their lives in the telephone industry, are thrown idle without the possibility of obtaining employment in their own field. It must be remembered in this connection that the telephone industry is practically a Government monopoly, and whereas men discharged in other walks of life have the opportunity of obtaining work with employers of the same nature as those by whom they were discharged, the telephone man has no alternative employer.

The remedy lies with the Government, who are pledged to deal with the unemployed question, yet are directly or indirectly responsible for its aggravation in the manner indicated. The Government can either take into their employ the men discharged by the company, and construct the lines which the company are daily refusing, or they can, by financial assistance, keep going the constructional works which would be carried out by the National Telephone Company but for its transfer to the State, and thus give employment to the men who are now being discharged. For every telephone subscriber who is connected now is a potential asset to the Post Office.

The question of economy which was pleaded in the case of the Woolwich discharges cannot now be raised, as the work is of a remunerative nature; so much so, that the National Telephone Company were able to realise a profit of £480,641 during the past half-year, a sum which is £40,661 in excess of a similar period in 1907, and which enables the company to pay a dividend of 6 per cent. for the half-year on all its stock, and add £140,000 to the reserve fund, making its total £2,664,960. The only reason which causes the company to refuse orders is its inability to see a profit in the three years it has still to exist. This fear, however, does not apply to the Post Office, who are masters of the situation, and who would be undertaking profitable work were they to accept the orders which the company are refusing, and to employ the men who are at present being discharged for the construction of the lines.

The following correspondence has since passed between the editor of ELECTRICAL ENGINEERING and the Society:—

"ELECTRICAL ENGINEERING,"
203-6 TEMPLE CHAMBERS,
LONDON, E.C., *Sept. 14th*, 1908.

The Secretary,
The National Society of Telephone Employees,
4 Great James Street, W.C.

DEAR SIR,—I notice that a statement has been circulated to the daily papers, and published this morning, to the effect that nearly one thousand men have been discharged from the service of the National Telephone Company, and that six thousand men will be discharged prior to 1911, when the Company's licence expires. From the wording of the statement, it is not clear to me whether the object in issuing it is to ventilate a grievance against the Company, or to make an actual endeavour to replace in work the discharged men. If the latter has been the case, however, I am somewhat surprised that the statement should not have been circulated to the electrical engineering journals which are read by the heads of technical departments likely to employ such workmen. If, however, the latter is really the true reason of your publishing the statement in question, I should be obliged if you will give me information on the following points, in order that I may publish it in our issue of this week:—

1. How many men of each trade and from each district have been discharged?
2. The period during which nearly one thousand men have been dismissed is not mentioned in the statement. This is a material point, and I should be glad to be informed with regard to it.
3. How many men were discharged during the corresponding period of last year?
4. Has any other reason been given for these discharges other than slackness of work?
5. What is the actual authority for the statement that "6,000 men will be discharged prior to 1911"?
6. Your statement says that "orders for telephones are being refused by the hundred, and men who should be employed in the construction of lines are thrown idle." Can you give me any figure to substantiate this, for the statement hardly appears to agree with that made by the Secretary of the National Telephone Co. on the occasion of the last staff dinner of the Company, in which the increase in the number of telephone stations during the previous twelve months was quoted. Perhaps you can give me the number of additional telephone stations that have been connected, say, during the last three months, compared with the number for the corresponding period of last year?
7. How is it that none of the discharged men have been re-employed by the Post Office? It would appear that if it is true that the National Telephone Co. are refusing subscribers in order that the stations may be connected to the Post Office exchanges instead of to those of the National Telephone Co., exactly the same number of men would be needed to connect up these stations, and the work would be not diminished.
8. Have you any figures to prove that the aggregate number of linesmen, electricians, exchange employees, clerks, and others employed on telephone work in this country is diminished?

I have asked you for a considerable amount of information in the above questions, but I have no doubt that you will be able to reply to them with little trouble, as doubtless the statement which you have issued to the daily Press must be based on definite information and figures of this sort.

Awaiting your reply, Yours faithfully,

F. CHARLES RAPHAEL,
Editor.

4, GREAT JAMES'S STREET,
LONDON, W.C., *Sept. 15th*, 1908.

To the Editor, ELECTRICAL ENGINEERING.

SIR,—In reply to yours of 14th inst., I must request you to carefully re-read the statement as published in the *Daily Telegraph* of 14th, when you will see that there is no indication of a desire "to ventilate a grievance against the company," and no suggestion that this society is agitating unnecessarily against a party whom it recognises is only acting in a businesslike manner.

The object of the statement is to arouse public opinion on this question to aid the society in its endeavours to get the Government to take the question into consideration either for the direct employment of the men discharged or to financially assist the company to carry out those constructional works which are necessary if the legitimate extension of the telephone industry to 1911 and immediately after is to be carried on.

With regard to your series of questions, I am not at the moment in a position to divulge all the information I have to the public Press, but it is needless to say that a statement of the character which has been issued by the society must necessarily be backed by ample evidence. However, there are certain points raised on which I can give you some enlightenment.

1. For answer to this see Answer No. 8.
2. The period during which nearly one thousand employees have been discharged is, roughly, six months.
3. During the corresponding period of the previous year there was an increase in the total staff employed.
4. Completion of constructional works is the reason officially given as the cause of discharges. But here I would refer you to the interview with Mr. Franklin, President of the company, in to-day's *Daily Mail*, as a direct confirmation of the society's statement.
5. The authority for the statement that 5,000 to 6,000 men would be discharged is that of prominent officials of the Telephone Company, whom it would be invidious to name. This is also confirmed in the interview with Mr. Franklin indicated above.
6. The statement that "orders are being refused by hundreds" is one which can also be substantiated and one which the society made by the advice of its members in the Contract Departments of the company's service. I may add that instructions have been issued to many districts, including the metro-

Digitized by Google

politan, that all orders for line whose cost of construction would exceed a very limited sum are to be refused, thus stopping the larger constructional jobs and consequently diminishing the staff previously required.

7. I am unable to state the reasons why the Post Office refuse to employ the discharged men. It appears to me that application for information on this point should be addressed to the Postmaster-General. Your reasoning is inaccurate, as it must be remembered :—

(1) That the P.O. system in London is an underground one, and the N.T.C. aerial, and therefore once a P.O. cable is laid there is less constructional work required than under the N.T.C. system.

(2) That in the vast majority of centres throughout the country, such as Manchester, Liverpool, Leeds, Bradford, Birmingham, Bristol, &c., the Post Office have no telephone system for local calls, and therefore when the National Telephone Co. cease constructional work telephone development entirely ceases.

8. We hold figures that the constructional staffs, both engineering and electrical, and also the contract or canvassing staff in this country have considerably diminished during the past six months. But I consider it inadvisable to give our figures at the moment, firstly, because they are not official figures, which can only be obtained from the company; and, secondly, they are supplied by our branch correspondents. The number of discharged shown by them is probably less than the actual total, as there are still a few centres in which this society is not represented whose number of discharged men are not included.

In conclusion, I may say that no disrespect is or was intended to the electrical Press by the issuing of the statement to the daily Press, as the reason for the issue of the same was to arouse public opinion, which the electrical Press are not in touch with, and, further, it was known that the heads of departments in the telephone industry are already fully informed as to the position of affairs.

The writer of this would be pleased to be interviewed by you to add to this already lengthy statement of affairs, if you will notify him of your desire to do so.

Yours faithfully,

R. JEFFREYS,

Assistant Secretary.

Mr. George Franklin, President of the National Telephone Co., has authorised the publication of the following interview with a Press representative; part of this interview, published in the *Daily Mail*, is referred to in the above letter.

It was alleged that orders for telephones were being refused by the hundred, and the discharges already approached 1,000. Mr. Franklin pointed out that the telephone company were in no way responsible for the statement, and added, "It is quite true that there must be some limitation of expenditure in the closing years of the business, because, obviously, the company cannot go on spending capital which would not be productive within the period of the license, and for which they might only receive a depreciated value. That is really the basis of the whole question.

"I very much doubt the statement that the discharges already approach 1,000. There have been discharges; and, of course, there must be more as time goes on. The company, with all the willingness in the world, cannot go on employing labour if they cannot make anything productive out of it. The total number of employees affected before 1911 might approach 5,000 or 6,000."

The President denied the statement that orders were being refused by the hundred. "We are," he said, "undertaking all the orders we can. At present, as a matter of fact, we have a smaller number of unexecuted orders on our books than for many years past. That may be due to bad trade. It should be clearly understood that the company are not in any way ceasing to give people who desire it a telephone service. What we are ceasing to do is to provide capital that will not be productive."

Mr. Franklin referred to the position of the Government, saying that the company were ready to do anything that was possible to meet the case. "All that is required is that we should be satisfied that any money spent on behalf of the period subsequent to 1911 shall be recouped to the company without loss. It would be a great advantage, I think, to the Government if some method can be found, and probably some method may be found. The company have had to adopt this policy, but would welcome some way by which the control of the expenditure should be exercised by the Post Office, and the company would be recouped for their expenditure."

The *Daily Mail*, however, adds :—

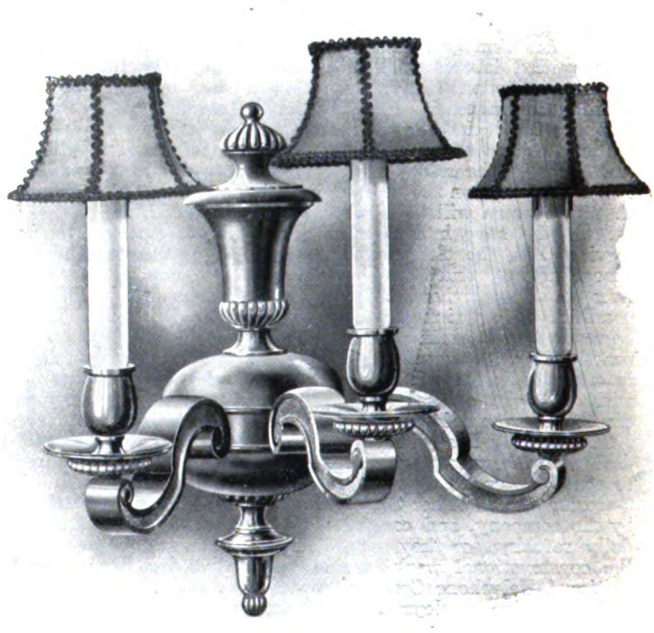
An official of the Post Office telephone department stated that, as a matter of course, all the employés of the company would be taken on by the Government. "When the Post Office takes over the system," he said, "there will no doubt be much extra work, and men who have been in the service of the National will be given work."

CATALOGUES AND PAMPHLETS RECEIVED

BATES & PEARD ANNEALING FURNACE.—A new leaflet has been published by the British Insulated & Helsby Cables, Ltd., Prescot, upon the Bates & Peard patent annealing furnace, which will deal with copper, brass, nickel, aluminium, gold, silver, and all non-ferrous metals. This furnace consists of an airtight chamber or tube, the ends of which descend into and are sealed by water baths. The annealing chamber is set in a brick or other heating furnace, which may be fired by gas, oil, or coal. The metal to be annealed is placed on an endless chain conveyor, and is automatically passed, first through one water seal, then through the heated portion of the tube, then out through the other water seal by which it is cooled, the water seals, therefore, forming entrance and exit doors to the furnace.

BRITISH CORRESPONDENCE SCHOOL OF ELECTRICAL ENGINEERING.—A second edition of the new syllabus has been issued from 36 Maiden Lane, London, from which we notice that the scope of the work of this school has been enlarged. Several new courses have been added, notably those on Tramway and Railway Engineering, and Electrical Problems and their Solution.

ELECTRIC LIGHT FITTINGS.—Messrs. Galsworthy, Ltd., of Newman Street, Oxford Street, have issued an artistic little pamphlet describing their latest patterns of electroliers and other



fittings. The illustrations are in two colours, and a general view of their show-room is included in the pamphlet. Among the illustrations is one of a candelabra in the Georgian style, which we reproduce above.

"METALITE" LAMPS.—A leaflet from the Bryant Trading Syndicate, Ltd., Horsell Road, Highbury, London, deals with the "Metalite" lamp, which we described fully in our issue for April 10th, p. 592. These are made in all sizes from 17 to 40 c.p., 100 to 130 volts, and 34-40 c.p., 200 to 250 volts. The consumption of the 32-c.p. lamps is one watt per candle. These are claimed to be the only metal filament lamps entirely made in England.

NEW SLIDE RULE.—We have received from Mr. M. J. Eichorn, of 5759 Aberdeen Street, Chicago, a description of a new trigonometric slide rule for solving triangles. In order to find the third side of a triangle when the two others and the angle between them are given, a direct manipulation of the slide only is necessary. If the three angles and one of the sides are given, a double-line sine-scale on the back of the slide is made use of. This scale is also used when two sides and an opposing angle are given. When all three sides are given, a direct solution with the face of the rule is possible.

THE PRESCOT WELDER.—The various types of the Prescot Welder are described and illustrated in a booklet received from the British Insulated & Helsby Cables, Ltd., Prescot. These machines have now been designed to deal with copper, brass, iron, and weldable steel up to 2 in. diameter, mild steel tape, and for armouring electrical cables, perambulator rims, chains, &c. In cases where suitable electrical power does not already exist, the company supplies a special self-exciting alternating-current generator, which can be driven from any shafting and need not be near the welder.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 10th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

14,059. **Train Lighting System.** H. GROB. A series dynamo, driven from a train-axle, is connected across a battery of accumulators, and the exciting current is thus dependent upon the difference of pressure of the two sources of E.M.F. The lamps are connected across the armature brushes. A second battery is continually being charged by one of three methods. In the first method the dynamo is supplied with an auxiliary armature winding and commutator, and this winding in series with the main armature winding generates the higher pressure needed for charging. In the second method the lamp circuit, which is in parallel with the working battery, is supplied from auxiliary brushes on the commutator, which are displaced less than 180°. In the third method the lighting and the charging current are taken from the main brushes, while the auxiliary brushes are connected to the exciting winding and the working battery. In this case a resistance in series with the lamp circuit is needed. At very high speeds the residual magnetism of the dynamo field may cause reversal of the exciting current, but to prevent this, a negatively acting field-winding supplied from the auxiliary armature winding of the first method is provided. The usual centrifugal cut-out for the dynamo is used, and means for changing over the batteries at regular intervals must be provided. Nine claims, five figures.

27,543. **Tension Springs for Metal Filaments.** E. A. GIMINGHAM (EDISON & SWAN UNITED ELECTRIC LIGHT CO.). A method of manufacturing helical springs for exerting a small but constant tension on the metal filaments of electric lamps, and capable of withstanding high temperatures. The method consists in attaching one end of a weighted fibre of glass or quartz to a heated platinum mandrel, and then slowly rotating the mandrel at the proper angle to produce the helix. Five claims, one figure

1908 Patents

2,307. **Ozone Water Steriliser.** A. DE BOUILLANNE. An apparatus for sterilising water by means of ozone. The principal feature is that the water is broken up into very fine drops, and the resulting cloud is given a gyratory ascending motion in a bell from the upper part of which the ozonised gas descends in the direction opposite to that of the water, thus ensuring an intimate mixture. Three claims, four figures.

4,274. **Brushholders for Motor Meters.** C. E. J. O'KEENAN. This is a device to compensate for the perturbations due to the friction of the brushes in motor meters, especially at light loads. The brushes are mounted on the armature of an electro-magnet, provided with a make-and-break contact device. It is said that the oscillatory motion in a direction tangential to the commutator thus imparted to the brushes, compensates for the above-mentioned perturbations. Four claims, nine figures.

11,511. **Platinum Contacts.** SIEMENS BROTHERS & CO., LTD. (*Siemens & Halske Akt. Ges.*). A contact for electrical apparatus consisting of a support of copper or brass enclosed in a cap of platinum. The amount of the non-oxidising precious metal is reduced to a minimum, while the copper gives the required strength, and also serves for fixing to the contact springs by rivetting. One claim, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

12,072, MAVOR, & MAVOR & COULSON, LTD. Motor equipments for marine propulsion.
16,781, SCHALLER. Pressure regulation on a network supplied by a variable speed generator.
18,764, LEADER. Railway signalling apparatus.
19,241, LECOCHE. Electro-magnetic cut outs.
19,424, MAVOR & BILES. Electrical propulsion of marine vessels.
19,562, DEUTSCHE GASGLUHLICHT AKT.-GES (AUER GES.). Suspension of metal filaments.
20,068, HUNTINGTON. Switches.
20,495, JACOBY. Speed regulation of alternating current commutator machines.
21,197, ASSERSOHN. Fittings for tubular lamps.
22,211, OPPERMANN. Secondary batteries.
22,526, JACOBY. Alternating current motors.
23,303, MAJOR, STEVENS, & STEVENS. Electric lifts.
23,809, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Wire stringing devices for insulating wire.
24,291, SPRAGUE & HOOKHAM. Counting trains for meters.
24,486, HAGEN. Electrodes.
24,992, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Dynamo-electric machines.
25,340, HOLT & WALLIS. Track circuits for railway signalling.
25,553, LÉVY. Electro-deposition of metals.
26,352, WOOLLISCROFT. Brush holders.
26,844, BARTELS, & LAND-UND SEEKABELWERKE AKT.-GES. Sparking-devices.
27,926, ALLGEMEINE ELEKTRICITÄTS GES. Electric welding of rings, hoops, and chain-links.

1908 Patents

69, CASPAR. Manufacture of refractory substances.
1,502, HOOKHAM, & CHAMBERLAIN & HOOKHAM, LTD. Electricity meters.
1,517, SIEMENS BROS. DYNAMO WORKS, LTD., & LYDALL. Apparatus for stopping railway or tramway vehicles in case of failure of the driver.
1,606, MARSHALL & PENMAN. Railway Signalling.
3,056, STRUBLE. Alternating-current relays.
4,111, SIEMENS BROS. DYNAMO WORKS, DALZIEL, BROOKS, & JENKIN. Recording apparatus for use with electrical measuring instruments.
4,181, LASSEN. Electrically-propelled motor-car.
5,016, HARRISON (*Electric Railway Improvement Co.*). Bonding rails.
5,054, NEALE & POWELL. Electric clocks.
5,271, BUTTERWORTH. Automatic fire and heat alarm.
5,444, VARELA. Electric automatic sounding apparatus.
6,170, MAWDSLEY. Brush holders.
9,569 JAEGER. Electric wire poles or masts for electric wires.
10,343, KITSEE. Preventing induction between conductors.
10,929, GAZZARD & MILLER. Emergency brake.
11,346, GUILLOT. Insulators for overhead systems of electric railways.
12,389, SIEMENS BROS. DYNAMO WORKS, LTD., & KLOSS. Oil switches, &c.
13,133, DEGOUMOIS. Brakes for electric cars.
13,450, SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*). Fuse holders.
14,116, KITSEE. Telegraphic relays, or receiving devices.
14,262, NOY. Fenders or guards for tramcars.
15,377, CONDON. Electrical water heaters.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

13,451, SIEMENS-SCHUCKERTWERKE GES. Repulsion motors.
17,349, VON LEPEL. Apparatus for producing rapid electric oscillations.
17,421, KÖRTING & MATHIESEN AKT.-GES. Arc lamps.
17,535, ALLGEMEINE ELEKTRICITÄTS-GES. Arc lamps.
17,536, ALLGEMEINE ELEKTRICITÄTS-GES. Controller for cranes and lifts.
17,618, ARSEIN. Manufacture of refractory conductors.
17,619, FULLER. Manufacture of refractory conductors.
17,620, COOLIDGE. Manufacture of refractory conductors.
17,621, COOLIDGE. Manufacture of refractory conductors.
17,622, ALLGEMEINE ELEKTRICITÄTS-GES. Electric cranes and lifts.
17,687, PHEYSEY. Electric heating apparatus.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of Sept. 9th, 1908.

12,329, of 1906. **Electric Furnaces.** THE GRÖNDAL KJELLIN CO., LTD., seek leave to amend this specification granted to H. RÖCHLING and W. RODENHAUSER for "Improvements in electric furnaces." The amendment consists in striking out Claim 4, which is said to be of questionable validity.

Expiring Patent

The following patent expires during the current week after a life of fourteen years :—

17,774, of September 18th, 1894. **Telephonic Apparatus.** THE PHONOPORE CO., LTD., and E. W. SMITH. Calling apparatus for telephony, consisting of a relay with a vibrating magnet armature and a bell circuit. Also a switch-hook for cutting out the receiver and connecting the relay magnet coils to the line when the telephone is not in use.

LOCAL NOTES

ABERDEEN: *Tramway Receipts.*—The receipts upon the tramway system from the beginning of the financial year amounted to £23,303, a decrease of £119 compared with the corresponding period of last year.

Underground Telephone Wires.—It is announced that the Engineer's Department of the General Post Office have made great progress with the scheme of laying the telephone wires underground. Most of the central thoroughfares have now been trenched, and the conduits laid, and work is now proceeding in the outlying districts.

ARBROATH: *Electricity Works Assessment.*—The valuation of the electric lighting works has been fixed at £225 for the present year. This is a considerably lower assessment than will be the case when the works are fully equipped and fully employed.

BELFAST: *The Engine Contract.*—Arbitration proceedings are to take place between Messrs. J. G. White & Co. and the Corporation, with reference to the engines used in connection with the tramway supply. The Council has decided to retain Mr. A. E. Porte to give evidence on their behalf.

BELGIUM: *Ghent.*—An American Consular report gives some particulars of the new harbour and deep canal which is to be constructed in order to connect Ghent with the sea-coast. There are to be a number of lift bridges over the canal, which will be opened and closed electrically, whilst arc lamps will be placed at intervals of 490 ft. along the total length of 20 miles of the canal.

BRADFORD: *Street Lighting.*—In connection with the experiments decided upon of lighting a certain portion of the streets by electricity and gas for the purposes of comparison, the Electricity Department has decided to make use of flame arc lamps attached to the tramway posts. There are 18 lamps of 2,500 c.p. each, and the length of the thoroughfare lighted is about 640 yards. So far the Gas Committee have not decided upon steps which they will take in the competition.

BRISTOL: *Tramway Inspection.*—Lieut. Col. von Donop inspected the first portion of the new Westbury tramway extension last week, and the line was subsequently opened to the public.

BURSLEM: *Electricity Statistics.*—The number of units generated during August was 32,745, the number for the corresponding period of last year being 22,145. The total number of 8 c.p. lamps or their equivalent, in use, exclusive of street lighting, is now 13,547, against 9,423 last year, whilst the motors installed have a total capacity of 493½ h.p., against 319 h.p. in August of 1907.

BURTON: *Electricity Undertaking.*—In submitting the report of the Gas & Electricity Committee at the last meeting of the Council, the Chairman called the attention of the Council to the gratifying increase in the consumption of electricity, which was almost entirely due to the power consumers.

BUXTON: *Refuse Destructor Works.*—The new refuse destructor works, which has been erected by the Council in connection with the electricity works, are now completed.

CANADA: *Montreal.*—The Canadian Electric Light & Power Co. has been granted powers to give a supply of electricity in Montreal. The contract provides for the commencement of a supply within two years, and a schedule of charges has been arranged which is said to be considerably lower than any at present existing.

CHESTERFIELD: *Tramway Report.*—The annual report of Mr. R. L. Acland, the Tramway Manager, states that the capital account for the year ended March 31st, 1908, has been increased by £1,263, being the cost of two new cars. The total capital expenditure upon the undertaking now amounts to £89,722, the total borrowing powers being £95,000. On the revenue side of the accounts the traffic expenses have increased from 2·34d. to 2·4d. per car mile. Repairs and maintenance have been reduced from 0·67d. to 0·63d. per car mile, there having been an increase on permanent way electrical equipment and fixtures, but a decrease on cars. The total cost per car mile has increased from 5·32d. to 5·78d. After meeting all liabilities and a contribution to the rates, there is a balance to renewals reserve and depreciation account of £978, compared with £922 last year. The following statistics are taken from the accounts :—Traffic revenue, £11,536; total revenue, £12,154; working expenses, £6,798; sinking fund and interest on capital, £4,378; car miles run, 282,228; number of passengers carried, 2,449,961; units per car mile, 1·31; percentage of working expenses to receipts, 56; total revenue per car mile, 10·34d.; reserve fund at March 31st, 1908, stood at £3,027.

CHIPPING NORTON: *Public Lighting.*—The Lighting and Watch Committee have drawn the attention of the Electric Lighting Co. to the unsatisfactory condition of the public lighting.

DUBLIN: *Financial Position of Electricity Undertaking.*—At the last meeting of the Corporation, Mr. Sherlock moved the following resolution :—"That the City Treasurer and City Accountant be requested to inquire into and report to Council upon the general financial position of the Corporation electricity undertaking; that the report detail the names, positions, and salaries of all employed thereon; and that reference be made in the report to the original estimates of Mr. Hammond and the various promises made by the Lighting Committee in regard to extensions and how far they have materialised." It was time, he said, that the Corporation should take same active steps to inquire as to the general position of the electricity works. After some discussion the resolution was carried.

EAST HAM: *Tramways.*—The Tramways Committee reported on Tuesday having considered a letter from the Board of Trade to the effect that they were advised that the bridge carrying the Romford Road tramways over the London, Tilbury & Southend Railway at Forest Gate does not satisfy the requirements as regards the strength of cast-iron over-bridges, and they therefore cannot grant a certificate to permit the tramways to run over the bridge until same is strengthened. The Borough Engineer has made drawings showing the proposed means of strengthening the bridge, and same are to be forwarded to the Railway Co. and the Board of Trade for their approval. In the meantime temporary arrangements have been made with the West Ham Corporation for running the new section up to the western side of the bridge and having communication between the two tramways there.

EDINBURGH: *Cost of Electric Power.*—The Electric Light Committee has resolved to recommend the Town Council to reduce the minimum charge for power for electric motors from £2 to £1 10s. per annum.

National Exhibition Finance.—A statement as to the financial position of the Scottish National Exhibition of the first four months of its existence, states that the cost of electric light and gas, and upkeep, has been £4,400.

FALKIRK: *Electric Lighting Tariff.*—The Electric Light Committee recommend that the price of electricity for lighting purposes be reduced from 5d. to 4d. per unit, and that the charge for lamps outside shops, offices, &c., for which separate meters are used, shall be 3d. per unit. It is stated that this latter special rate is proposed in view of the aid such lamps afford in the illumination of the streets, and with the object of inducing more business people to erect such lamps outside their premises.

FINLAND: *Electric Lighting.*—A Consular report upon the trade of Finland during 1907 states that public and private electric lighting has been brought into use in Lovisa. A new form of electric bath has also been introduced into the well-known hydropathic establishment there.

HALIFAX: *Tramway Compensation Claims.*—The special subcommittee of the Tramways Committee, which has been dealing with the claims for compensation in respect of the Pye Nest tramway accident, has reported that the claims number 50 in respect of personal injuries, seven for damage to property, and twelve others. With the exception of two personal injuries all the 74 claims have now been settled, at the estimated cost of £11,000. The liability of the Corporation, however, will only be £10,000, as the sum of £1,000 has already been received from the insurance company in respect of their indemnity.

Tramway Accounts.—The annual report of the tramway manager for the year ended March 31st, just issued, shows that the total capital expenditure amounts to £394,614. The total receipts amounted to £81,872, and the working expenses to £62,534. The gross profit is returned at £19,337, but as the capital charges reached £21,608, there is an actual loss on the year's working of £2,270. The total working expenses were 8·4d. per car mile, and the capital charges 2·91d. per car mile, making a total of 11·31d. per car mile.

Financial Position of Tramway Undertaking.—The Tramways Committee will hold a special meeting next week to consider the financial position of the tramways undertaking, and report with respect to through running, overlapping, and alterations in the service generally.

HARROGATE: *Electric Lighting Charges.*—The Engineer recommends that in order to obtain a bigger revenue from the lighting of small properties, a charge of 2s. 9d. per quarter for every 30-watt lamps be made on the following conditions :—(1) The amount to be paid quarterly in advance; (2) all apartments lighted under this tariff are to be adequately lighted by windows during daylight; (3) the maximum number of lamps per tenement to be three; (4) the number of applications to be limited to twenty existing customers and twenty new ones. During the discussion upon this proposal the Town Clerk stated that a part of it was illegal, but nevertheless the Council carried the Committee's report. The Mayor, however, stated that as the Town Clerk had ruled the proposal illegal, it was his duty to see it was not carried out.

HEYWOOD: *Electricity Undertaking.*—At the last meeting of the Electricity and Tramways Committee, the Chairman of the Finance Committee drew attention to the position of the undertaking. He said that there were signs that the loss at

Digitized by Google

the end of the present year would be £2,000 instead of £1,000 as last year, and that a decrease in the receipts of £100 and an increase in the expenditure of £100 had taken place during the past month.

Tramway Agreement.—At present the Corporation tramways in Heywood are worked by the Bury and Rochdale Corporations, but the agreement will shortly expire, and as the Heywood Council claims that it is entitled to better terms, it will not be renewed in its present form. A suggestion has been made that unless a better bargain can be made the Heywood Council shall work the cars themselves, but it is understood that as a result of the meeting between the engineers of the three towns, fresh terms have been practically agreed.

HYTHE: *Tramway System.*—A special meeting of the Society for the Preservation of the Beauty of Hythe has passed a resolution objecting to the proposal of the National Electric Construction Co. to substitute the overhead trolley system for the surface-contact system upon the proposed tramways between Folkestone, Sandgate, and Hythe. During the discussion it was mentioned that so far as the overhead system would not interfere with the beauty of the town, the Association would express no opinion, but they did not think it possible that the overhead system could be other than a great disfigurement to the district. The feeling of the members of the Society seems to be that visitors will stay away from Hythe if the overhead trolley tramways are introduced. At the meeting of the Council on Friday it was decided not to sanction any alteration in route or system. A poll of the ratepayers has been taken, which shows a majority in favour of the decision of the Council by 44. The electorate numbers 1,200 and 841 votes were recorded.

JAPAN: *Electric Traction.*—A British Consular report states that nothing was done during the past year in connection with the proposed electric tramway between Chofu and Shimonoseki, but preliminary arrangements in connection with the Moji electric tramway were completed. The rails are to be laid between Moji and Kurosaki *via* Dairi, Kokura, and Yawata, with a branch line to the Imperial Government Steel and Iron Works at Wakamatsu.

KIRKCALDY: *Electric Lighting Accounts.*—The report of the Electrical Engineer for the year to May 15th, 1908, shows that the total income was £10,118 and the working expenses £6,327. From the credit balance of £3,790, interest on capital and sinking-fund charges absorb £3,653, leaving a net credit balance of £137. An analysis of the expenditure shows that the cost of fuel has increased from 0·385d. to 0·536d. per unit sold, the quantity consumed per unit being 9·83 against 9·372 last year. During 1908, however, Lochgalley coal was used, whilst Bohwell coal was used last year. Works costs are 0·89d. per unit against 0·75d. for the previous year, the total costs being 1·10d. against 0·98d. for last year. The units sold to private consumers for lighting purposes have increased by 33·6 per cent., and attention is specially drawn to this satisfactory rate of increase in view of the adoption of the higher efficiency metal filament lamps. The consumption by power users has increased by 67 per cent., and in this connection it may be pointed out that the load factor is gradually rising, being now 19·5 per cent. The total number of units sold was 1,381,106, of which 679,069 were for tramways, 100,378 for public lighting, 206,314 for private lighting, and 395,345 for power purposes. The average price received was 1·752d. per unit, compared with 1·657d. per unit for the previous year, when the output was 1,178,223. The total equivalent 3-c.p. lamps connected is 42,413 and the number of consumers 422, the figures for last year being 34,850 and 341 respectively. The maximum load was 811 kw., compared with 723 kw. last year. The estimates for the current year's working show a profit of £393.

Tramway Accounts.—The accounts of the tramways undertaking for the same period show that the total receipts were £14,993 and the working expenses £10,069. Interest on capital sinking fund, and depreciation amounts to £4,900, leaving a net balance of £23. The working expenses amounted to 5·26d. per car mile against 4·95d. last year, this increase being entirely accounted for in the cost of current, which has been charged at 1½d. per unit against 1⅛d. last year. Mention is made in the report of an improved working arrangement with the Wemyss Tramway Co., whereby the wasteful blanketting of the Wemyss cars alongside the Corporation cars has been got over. The total number of passengers carried upon the Kirkcaldy cars was 4,264,419, whilst the Wemyss cars under the through-running arrangements carried 609,780. The corresponding figures for last year were 4,369,835 and 270,783. The committee again recommend the favourable consideration by the Council of an extension to Dysart. The estimate for the current year's working shows a profit of £836. On the question of depreciation the committee recommend that a definite scheme for renewals and depreciation should be drawn up subject to reconsideration at period of five years.

LONDON: *Southwark: Electric Power Supply.*—The Electricity Committee of the Borough Council report that they have considered the London Electric Supply Bill and the London & Westminster & Kensington Electric Supply Cos.' Bill. The committee look with disfavour upon the proposals, which will enable the companies, numbering 15 in all, to link up their concerns, as the companies will thereby be enabled to combine for the purposes of supplying the current in competition with the Council's undertaking, and on such terms as are likely to seriously affect and be detrimental to the commercial interests thereof. The committee feel that if a general scheme for the co-ordination of the electric supply throughout London is to be carried out, a serious injustice would be done to the ratepayers, in the absence of any reservation clause being inserted in the Bills making it obligatory to purchase such undertakings as the Southwark Council's at a fair value, and before the plant is depreciated by cheap current being forced in competition. A petition is to be presented against both Bills.

St. Pancras: Reinstatement of Roads.—Last year £400 was charged to the Electricity Department for reinstating paving, &c., over trenches, £119 was charged to the Post Office telegraphs, £22 to the National Telephone Co., and £60 to sundry electricity, &c., companies.

Tramways.—A Joint Committee, which has been negotiating with the London County Council in regard to the electrification of the tramways from Euston Road to Holloway, has (subject to the usual sanction) approved the plans conditional upon the wood paving being retained in the tramway tracks of Hampstead Road and High Street, Camden Town. There are some small matters which are still the subject of negotiation.

MELTON MOWBRAY: *Public Lighting.*—The Lighting Committee have received a letter from the Electric Light Co. with regard to the contract for street lighting which expires at the end of the present year. The Committee, however, were unable to come to a decision as to advertising for fresh tenders, and have left the matter for the Council to decide.

PONTYPRIDD: *Tramway Men's Union.*—A branch of the Amalgamated Tramwaymen's and Vehicle Workers is to be formed by a combination of the tramwaymen of the Pontypridd and Rhondda districts.

RAMSGATE: *Tramway Nuisance.*—The Manager of the Isle of Thanet Electric Tramways & Lighting Co. has had his attention called to the fact that some of the old cars in use by the company are considered by the Town Council to be a source of annoyance and danger.

SHEFFIELD: *Tramway Funds and Unemployed.*—At a Council meeting last week it was decided to vote the sum of £10,000 from the tramway funds towards starting relief works of various descriptions.

SUNDERLAND: *Position of Electricity Undertaking.*—At the meeting of the Corporation on Thursday, Alderman Turnbull moved his resolution asking for details of the costs of electric supply to various large consumers, his reason being that the prices being charged were unremunerative. After a short discussion, however, the motion was overwhelmingly lost.

SWANSEA: *Inspection of Electricity Works.*—The annual inspection of the electricity works took place last week under the guidance of Councillor Sinclair, the Chairman of the Electricity Committee. At the subsequent luncheon, Councillor Sinclair stated that the works were started eight years ago with a capital expenditure of £60,000, which had now grown to £144,000. Between the two periods also the number of consumers had increased from 96 to 1,216, and, roughly speaking, they were connecting up four new consumers per week. With regard to the revenue, this in the first year was £4,571, whilst last year it was £20,824. He was happy to say that the undertaking had fulfilled all its financial obligations, and, in addition, made an absolute net profit of £800.

SWINDON: *The Tramway Undertaking.*—A resolution has been forwarded to the Council by the Ratepayers' Association expressing the opinion that the tramway undertaking should be sold, but by a large majority the Council has declined to take any action in the matter.

TAUNTON: *Tramways and Electricity Supply.*—In consequence of strong complaints as to the unnecessary use of the gongs on the tramways, a communication has been sent to the tramway company asking them to take steps to avoid this nuisance in future. Some objection has been taken to the recent resolution of the Council to supply the Tramway Co. with current at 1·2d. per unit, and at the last meeting of the Council a resolution was moved that the price be 1¼d. It was pointed out, however, that the previous resolution could not be rescinded.

TURKEY: *Importation of Telephones.*—In addition to the withdrawal of the prohibition of the importation into Turkey of electrical instruments, the Board of Trade have received a dispatch from the British Consul-General at Constantinople reporting that the prohibition of importation has also been withdrawn in the case of telephones, amongst other goods.

WALSALL: *Tramways.*—The Wolverhampton District Electric Tramways, Ltd., have agreed that the increased payment of 1½d. per car mile to be made by the company to the Corporation in respect of the mileage run by the cars of the Corporation over the company's line at Willenhall shall commence as from July 1st last.

WEDNESBURY: *Electricity Supply.*—It is stated that quite unexpectedly the Midland Electric Corporation for Power Distribution has notified the Corporation of its intention not to supply in the district any further. It will be remembered that serious competition was threatened between the company and the Corporation owing to the latter having decided not to take

Digitized by Google

power in bulk from the company any longer, owing to a disagreement over the price. Both the company and the Corporation possess supply powers in Wednesday, and a loan was recently granted to the Corporation for the erection of a generating station. The action of the Company has not placed the Corporation in any dilemma, as their preparations are sufficientiy far advanced to enable them to take over the company's consumers when the latter's notice expires.

WELLINGTON (N.Z.): *Electricity Accounts.*—Since the undertaking of the Wellington Electric Light Co. was taken over by the Corporation eleven months ago, it is estimated that the profits for the year will be about £700 more than those of the company during the last year of its life, in spite of the fact that the municipality has reduced the price to consumers which will reduce the revenue by about £3,000. After setting aside £13,000 for capital charges and depreciation, a net profit of about £5,000 is shown for the eleven months' working.

WORKSOP: *The Engineer's Salary.*—A motion to increase the salary of Mr. J. C. Crowther, the Borough Electrical Engineer, to £200 per annum, with further annual increments of £25 per annum until a maximum of £300 is reached, was rejected at the last meeting of the Corporation by 8 votes to 6.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—In connection with Mr. C. H. Merz's report upon the electrification of the Victorian railways, tenders may be looked for shortly for a scheme involving an expenditure of some £800,000.

BURSLEM.—A Local Government Board inquiry was held on Thursday into the application by the Corporation to borrow £12,000 for the purposes of the electricity undertaking.

BURY.—A Local Government Board inquiry into the Council's application for sanction to borrow £72,000 for electricity developments, new works to be built at Chamber Hall, was held last week.

DARWEN.—An inquiry was conducted by the Local Government Board last week into an application by the Corporation for powers to borrow £4,300 for the new electricity undertaking.

HULL.—The Tramways Committee invite tenders for the supply and erection at the Osborne Street power station, of a surface condensing plant with motor-driven pumps, capable of dealing with 20,000 lbs. of steam per hour. Particulars from the City Engineer (fee, £1, returnable), and tenders to the Chairman of the Tramways Committee, Town Clerk's Office, by September 18th.

ILFORD.—An overhead travelling crane is required by the Electricity Department. Particulars from the Electrical Engineer (fee, £1 1s., returnable), and tenders to the Town Clerk by September 22nd.

LEITH.—The Tramway Committee have resolved to recommend the Council to proceed with extensions of the tramways from Bonnington Terrace to Pier Place. It has been further agreed to recommend that the work be carried out by the Corporation employees.

NEATH.—A loan of £18,000 for electric lighting purposes is to be applied for, made up as follows:—purchase of the South Wales Electrical Power Co.'s generating station, £7,000; overdraft, £597; extensions of mains and services, £4,764; over expenses, £1,700; extras, £1,000.

TAUNTON.—A double acting steam engine is to be purchased at an estimated cost of £300.

WIMBLEDON.—A Local Government Board inquiry was held last week into an application by the Corporation to borrow £6,000 for the purposes of the electrical undertaking. Of this sum £1,059 represents excess of expenditure over previous loans, and the remainder is the estimated cost of mains, sub-stations, &c., until March, 1909.

Miscellaneous

BLACKPOOL.—Tenders are invited for the following materials by the Tramways Committee:—100 tons of steel rails, No. 4 B.S. Section, 30 cwt. of fishplates, 20 cwt. of tiebars, 300,000 (about) hardwood paving blocks. Particulars from the Borough Engineer, and tenders by September 19th.

HULL.—Tenders are invited for one year's supply of ironwork, and one year's supply of insulator bolts and caps. Particulars from the Town Clerk (fee, £1 1s., returnable), and tenders by September 23rd.

PORTSMOUTH.—The Council has decided to extend the tramway system to Milton, which has of late years become a populous and growing suburb of Portsmouth.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations, and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.C.—Adaptation of premises in Holborn for occupation as branch of Capital and Counties Bank, 39 Threadneedle Street, E.C.

Buildings on sites of 33, 34, 35 Gutter Lane and 6 Carey Lane. Builder, J. W. Jerram, Crown Works, Boundary Road, East Ham.

N.W.—Buildings, Hampstead Road (near Euston Road). Builders, Howell J. Williams, Ltd., 11-17 Bermondsey Street, London Bridge.

S.E.—Additions to factory, Thurndley's Road, Deptford. Builder, G. Parker, 124 Sumner Road, Peckham, S.E.

W.—Hotel, Berners Street and Castle Street. Architect, John Slater, 46 Berners Street, W.; builders, Holloway Bros., Belvedere Road, Westminster Bridge.

Adaptation of 32 North Audley Street, Mayfair, for occupation by Edwin & Co., court hairdressers and manicurists, 49 Park Street, Grosvenor Square, W.

Adaptation of 37 North Audley Street, Mayfair, for occupation by Lewis Soloman, fruiterer, &c., Covent Garden Market, W.C.

Alterations to 2 Carlton House Terrace (£2,000); 74 Brook Street (£650); 7 Hyde Park Gate (£1,250); 45 Baker Street (£1,050); 12 and 13 Montagu Place (£1,640). Architect, F. W. Foster, 41 Bedford Row, W.C.

Re-building 439 to 451 Edgware Road (£7,700). Architect, F. W. Foster, 41 Bedford Row, W.C.; builder, C. Gray, Wellington House, S.W.

PROVINCES.

ALLOA (CLACKMANNAN).—Extension of County Buildings (£5,000). Architects, Melvin & Kerr, Alloa.

ASPULL (LANCS.).—Additions to Dicconson Mills.

BARNES.—Six houses, Bollo Lane. Builder, J. J. Fuller, 63 Ivy Crescent, Chiswick.

School (£5,000). Architects, Jarvis & Richards, 10 Queen Anne's Gate, Westminster; builders, R. T. Hughes & Co., Ltd., 37 Sheen Lane, Mortlake.

BARNET.—Completion of St. John's Church. Rev. E. J. Hall, Rector, Friern Barnet.

BELFAST.—Alterations to United National Club, Berry Street.

BELPER.—Public baths (£8,000). Builders, W. Ford & Sons, Summer Hill, Victoria Street, Derby.

BERWICK-ON-TWEED.—School (£8,000). R. Dickinson, Surveyor, Town Council.

BIRMINGHAM.—Mess-room and drill-hall, Metropolitan Road, for the Metropolitan Amalgamated Railway Carriage & Waggon Co., Ltd.

BOSTON.—School (£3,600). G. E. Clarke, Surveyor, Town Council.

BRIDGEND (GLAM.).—Additions to workhouse infirmary (£1,250).

BRIDGWATER.—Additions (£4,000) to Town Hall. F. Parr, Surveyor, Town Council.

BRIDLINGTON.—School (700 places). G. G. O. Sutcliffe, Clerk, Education Committee.

BRISTOL.—Addition to Ashton Gate Brewery. Architect, J. A. Wright, 6 Unity Street, College Green.

COLWYN BAY.—First portion (£1,065) of church. Architects, J. M. Porter & Elcock, Colwyn Bay.

CROYDON.—Additions and alterations, Baptist Chapel, Whitehorse Lane. Architect, E. Stones, 1 Trump Street, Cheapside, E.C.

Two houses and shops, Selhurst Road. Architects, Dartnell & Banks, 34 High Street, Croydon.

Twelve houses, Richmond Road. W. M. Lucas, 91 Brigstock Road, Croydon.

Additions to Whitehorse Laundry. W. Hards, 19 Selsden Road, Croydon.

Additions and alterations, 70 Westow Hill. Builders, Macey & Sons, 24 Essex Street, Strand, W.C.

Six houses, Whitehorse Lane. F. H. Milton, 76 Haslemere Road, Croydon.

Six houses, Barmouth Road. W. B. Coomber, 65 Pemdevan Road, Croydon.

Six houses, Melfort Road. C. Omerod, 5 Station Road, West Croydon.

Three shops and two houses, Brigstock Road. H. E. Davey, 20 Cassland Road, Croydon.

Additions, St. James's Vicarage, Tavistock Road. Builders, Umlandt & Gibson, 98 Cherry Orchard Road, Croydon.

School (£12,100). Architect, H. Carter Pegg, Thornton Heath; builder, W. Wallis, 207-9 High Road, Balham.

DARLINGTON.—Three houses and additions to Union Offices, Crown Street. Architects, Hoskins & Brown, Darlington.

DEVONPORT.—School (£11,180). Architects, Thornely & Rooke, 29 St. Aubyn Street, Devonport; builder, A. N. Coles, Plymouth.

Digitized by Google

DUDLEY.—Enlargement of post office. H.M. Office of Works, Storey's Gate, S.W.

FLEETWOOD.—Addition to cottage hospital (£1,500). Architect, B. Drummond, 4 Alfred Terrace, Fleetwood.

GAINSBOROUGH.—Refuse destructor (£2,000). S. W. Parker, Surveyor to Council; builder, A. J. Elmes, Gainsborough.

GLASGOW.—Church, Rose Street and Dalhousie Street, for Rev. A. C. Knight.

Offices in St. Vincent Street, for Northern Assurance Co. Head office, 1 Moorgate Street, E.C.

HENDON.—Additions to Workhouse Infirmary. F. J. Lea Crook, clerk to the Guardians.

KINGSTON-ON-THAMES.—Additions to Guardians' workshops, &c. Architect, W. H. Hope, 12 Clarence Street.

LEICESTER.—Additions to Fairfax Mills. Architects, Tait & Herbert, 28 and 18 Friar Lane, Leicester.

LICHFIELD (STAFF.).—Additions to Hammersmith School. G. Balfour, Education Offices, Stafford.

LUTON.—Two villas. Builder, F. Chandler, 78 Cromwell Road, Luton.

Bakery. Builder, A. Turner, 72 Hilbert Street, Luton.

Factory in George Street West, for Luton Cardboard Box Company, Ltd.

MERTHYR TYDVIL.—Eleven houses, for the Woodlands Building Club.

NOTTINGHAM.—Alterations to premises for General Life Assurance Company. Head office, 103 Cannon Street, E.C.

SHIPLEY.—Additions to Water Pits' Mills.

STOCKPORT.—High school (£15,000). J. Atkinson, Borough Surveyor.

SUNDERLAND.—Extension to St. Oswald's Mission Church, Corporation Road, for Rev. W. R. Egerton.

SWANSEA.—Additions to the Cambria Cold Storage Warehouse on the Strand.

Warehouse at the rear of 10 Picton Place for Mr. W. S. Clarke.

Additions to St. Winifred's Convent, St. James's Crescent, for the Rev. Mother Superior.

Additions to Hill Chapel, North Hill Road.

Additions to offices, Angel Chambers, Angel Street, for the United States Metallic Packing Co.

THAMES DITTON.—School (£4,150). Architects, Jarvis & Richards, 10 Queen Anne's Gate, S.W.

TILBURY DOCKS.—Residence (£1,150). Architect, C. M. Sliever, 10 John Street, Adelphi, W.C.

TWYNY-RODYN.—Additions (£8.683) to school. Architect, J. Llewellin Smith, Town Hall, Merthyr Tydfil.

WALSALL.—Country house. Architect, B. A. Porter, 88 Colmore Row, Birmingham.

WEST HAM.—Alterations, &c., in schools, for handicraft instruction. Architect, W. Jacques, 2 Fen Court, Fenchurch Street, E.C.

WEST HARTLEPOOL.—Alterations to the Brunswick Hotel, Brunswick and Musgrave Streets.

WIMBORNE.—Pumping station and other works in connection with Poole water supply. Engineer, Wm. Matthews, 39 Victoria Street, Westminster.

WORKSOP (Notts).—Public baths. Geo. Rawson, Surveyor to the Council.

YORK.—School (£10,289). Builders, Wm. Airey and Sons, 2 Claro Road, Servia Road, Leeds.

London's Electric Omnibuses.—The London Electrobus Co. has now 20 electric omnibuses in service in London, all of which are garaged at the Horseferry Road Garage, Westminster, which we described in our issue of December 5th, 1907, Vol. II., p. 903. A 'bus with a top cover on, after the style of that employed on tramways, will shortly be put on the service.

Electric Supply in the Bahamas.—As we announced a short while ago, the contract has been placed with Messrs. Crompton & Co., by the Crown Agents for the Colonies for the electric lighting of the city of Nassau, capital of the Bahama Islands. The consulting engineers are Messrs. Preece & Cardew, and the contract includes the supply and erection of all station plant, machinery, and mains. The plant will consist of three 81-b.h.p. Y.E.-type Crossley gas engines and suction-producer plant, the engines being direct-coupled through flexible couplings to three of Messrs. Crompton's standard continuous-current interpole dynamos, each capable of developing 45 kw. at 200/220 volts when running at a speed of 200 revolutions per minute. All the necessary circulating water pipes, two electrically-driven centrifugal pumps for circulating the water, a balancer set, dealing with an out-of-balancer current of 100 amps. in the middle wire, and a switchboard for the control of the three dynamos, balancer, and feeders. The mains will consist of overhead bare copper conductors carried on steel cross-arms mounted on wooden poles, on which brackets will also be mounted for carrying the incandescent lamps for street lighting. The contract includes the running of all service mains to consumers. The system of supply will be three-wire continuous-current, 100 volts for lighting, and 200 volts for power. The erection will commence about the beginning of October.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The *Australian Mining Standard* states that one of the earliest recommendations made by Mr. H. R. Forbes Mackay, City Electrical Engineer for Sydney, on taking up his duties, was that a storage battery be installed at the town hall sub-station as early as possible, in order to cope with emergency demands, which, at the present rate of development, will fall on the lighting station during the 1909 winter. Tenders were called, and at a recent meeting of the City Council, that of Messrs. Noyes Bros. (Sydney), Ltd., at a cost of £23,338, was accepted. The battery is of 300 Tudor cells, with a capacity of 4,000 amperes per hour, at one-hour rate of discharge. It has two automatic cell regulating switches; one charging booster set, consisting of a British Westinghouse three-phase 5,000-volt motor, and two booster generators, each to boost 2,000 amperes at 150 volts; and one motor-driven "Milking" booster. The contract for the supply of both alternating and direct current motors of over 5 h.p. for the City Council has also been obtained by the same firm for British Westinghouse motors.

BAHAMA ISLANDS.—We give particulars in another column of the contract which the Crown Agents for the Colony, through their consulting engineers, have placed with Messrs. Crompton & Co. for an electrical installation in the town of Nassau, the capital of the Bahama Islands.

EDMONTON.—At their last meeting the Guardians of the Edmonton Union had under consideration forty-two tenders which had been submitted to the specification of Messrs. May & Hawes, the consulting Electrical Engineers for the Electric lighting installation of the Nurses' Home. The tender of Messrs. Tilley Bros., 53 Kingsland Road, London, amounting to £376, was accepted. This is the first section of a large extension scheme which the Guardians are carrying out in connection with the new infirmary. The specification for the electric lighting of the infirmary itself will be issued in a few months' time.

GREAT WESTERN RAILWAY CO.—The contract for the erection of generating station buildings at Fowey, Cornwall, has been let to Mr. J. H. Endean, of Plymouth.

LEEK.—The following tenders have been received for a short length of cable:—Edison & Swan United Electric Light Co., £43; Callenders Cable & Construction Co., £37 17s.; W. T. Glover & Co., £37 17s. The tender of Mr. E. Phillips for the wiring of the station extensions at £19 has also been accepted.

LONDON: *St. Pancras.*—The Borough Council has accepted the tender of Messrs. Dorman, Long & Co., at £66 6s. 6d., for strengthening the stanchions of the old building in the King's Road generating station.

Stoke Newington.—The Council has accepted the tender at £46 19s. of James Keith & Blackman Co., Ltd., for the supply and fixing of an electric fan and case and air trunk for ventilating the generating station.

MANCHESTER.—The Lancashire Dynamo & Motor Co. have received an order from the Corporation for a three-wire hand-reversible booster.

The contract for a storage battery at Stuart Street Station has been given to the Tudor Accumulator Co., for the booster and switchboard in connection therewith to the Lancashire Dynamo Co., and for the low pressure pipe-work at Dickinson Street, to Messrs. Newton, Chambers.

METROPOLITAN ASYLUMS BOARD.—The following tenders have been received for the installation of a storage battery, booster, switchboard, and connections on board the training ship *Exmouth*:—Johnson & Phillips, Ltd. (accepted), £302; the General Electric Co., Ltd., £304; Pinching & Walton, £307; G. E. Taylor & Co., £310 13s. 3d.; Union Electric Co., Ltd., £312 5s.; Cox-Walkers, Ltd., £325; Watford Engineering Works, £327; Nursey & Marr, £345; Whipp & Bourne, £352; Edmundson's Electricity Corporation, Ltd., £354; Dargue, Griffiths & Co., Ltd., £365; Millwall Electric Co., £375 4s.; Pritchetts & Gold, Ltd., £382; the D. P. Battery Co., Ltd., £406; Electric Construction Co., Ltd., £409; W. Harvie & Co., Ltd., £410; Crompton & Co., Ltd., £415; Premier Accumulator Co., Ltd., £415; Chloride Electrical Storage Co., Ltd., £450; Siemens Bros. Dynamo Works, Ltd., £485; Electrical Power Storage Co., Ltd., £487; C. Pullan, £499; Hart Accumulator Co., Ltd., £520 17s.; R. Pope, Ltd., £555; S. Newton & Co., £715. The Engineer-in-Chief's estimate was £300.

STRETFORD.—The following tenders have been accepted:—boilers and pipe-work, Ed. Heaton & Sons, £1,860; mechanical stokers, Hodkinson & Co., Ltd., £286 12s. 2d.; economiser, Green's Economiser Co., Ltd., £492 18s.

SWANSEA.—The Town Council has accepted the tender of Glasbrook Bros., Ltd., for the supply of small steam coal (Garngoch) for 12 months.

WALSALL.—The Town Council has accepted the following tenders in connection with the electricity undertaking:—cast iron pipes, Lambert Bros.; flanged pipes, Roberts & Co. (socketted pipes); spare coil for the 66 kw. transformers, Thomas Parker, Ltd., £15 10s.; foundations for cooling tower, O. W. Wistance, £212.

Digitized by Google

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—The Westminster Electric Supply Company, Ltd., have, at the advice of their Engineers, Messrs. Kennedy and Jenkin, placed an order for five surface condensers for their new power station in the Horseferry Road, in the hands of Willans & Robinson, Ltd., Rugby, at £7,072 18s. 6d.

COMPANIES' MEETINGS AND REPORTS

BRITISH ELECTROMOBILE CO.—The report which has just been issued states that to March 31st there was a loss of £2,411. As the company has now a sufficient number of carriages available to meet the present demand, the directors have decided to close and sub-let the works. They have also decided to waive all claims to their remuneration as directors up to March 31st, and further, offer to cancel 3,928 shares of their respective holdings in order to write off the loss in revenue account, the preliminary expenses (£329) and the loss on fixtures, plant, and stock, mainly due to the closing of the works (£1,161), on the condition that eight founders' shares of nominal value of 1s. each be created, and that the Board shall have the right of subscribing for such shares in proportion to the shares surrendered. The founders' shares are to be entitled to a sum equal to 25 per cent. of the future profits of the company distributed in dividends on the remaining £12,447 ordinary shares.

CIA TELEGRAFICA, TELEFONICA, NACIONAL (Buenos Aires).—At the recent annual general meeting, the report and accounts were adopted, and a dividend of 7 per cent. declared. The profits amounted to $22,287 gold.

DIRECT WEST INDIA CABLE CO.—The accounts for the year ended June 30th, 1908, shows a net profit of £36,196, including the amount brought forward from last year. After providing for debenture interest, a further dividend of 3 per cent. is recommended, making the usual 6 per cent. for the year. During the year debentures have been paid off to the extent of £6,100, leaving £50,900 outstanding. The company's investments, apart from the value of its cable and equipment, are now valued at £58,850.

HALIFAX & BERMUDAS CABLE CO. There is an available balance, after providing for debenture interest, and including £17,848 brought forward from the last account, of £20,943 for the year ended June 30th. A further dividend of 2½ per cent. is recommended, making the usual distribution of 5 per cent. for the year. The carry forward is £17,193.

JOHNSON, LUNDELL ELECTRIC TRACTION CO.—A meeting was called for 11 a.m. on Wednesday last week at Cannon Street Hotel, but the Press were refused admission.

UNITED ELECTRIC CAR CO.—The report for the year ending June 30th, 1908, states that the works have been efficiently maintained as regards buildings and machinery, the cost of which has been charged against revenue. After paying debenture interest amounting to £2,500, and charging £5,677 for depreciation, the profit for the year is £7,092, to which is added £5,095 brought from last year, making a total of £12,187. Deducting preference dividend for the six months ending December 31st, 1907, there is an available balance of £9,187. The directors recommend the payment of the preference dividend for the half-year ending June 30th, 1908, which absorbs £3,000, carrying forward £6,187. Mr. Ludford C. Docker, owing to ill-health, resigned his position as a director during the year, and the directors have accepted his resignation with much regret. In his place the directors have elected Mr. Henry Mercer Malcolm, of London. The retiring directors are Mr. Kerr and Mr. Barningham, who offer themselves for re-election. The meeting will be held to-day at Preston.

Admiralty and Wireless Telegraphy.—The temporary installation of wireless telegraphy which was erected some time ago on the roof of the new Admiralty buildings in Spring Gardens is, says the *Daily Graphic*, being replaced in a permanent form in the three great towers overlooking the Horse Guards' Parade.

Marseilles Electrical Congress.—The International Electricity Congress in connection with the Marseilles Electrical Exhibition was opened on Monday, delegates being present from twelve countries.

Telegraph Traffic.—Telegraphic communication "via Kassala" was restored on the 9th inst. The submarine cable connecting Cadiz and Teneriffe was restored to working order on the 10th inst., having been inoperative since August 20th last. The Indo-European Telegraph Company's system ceased working on the 11th inst. between Tiflis and Tauris, and was in working order again on the 12th. The Lagos-Kotonou cable is still down. Telegraphic communication has now been established with the Island of Pemba, Zanzibar. The French Cable Company has again suffered a misfortune by the breaking of the cable between Cape Hayti and Mole St. Nicholas. Messages for Port au Prince will therefore have to go via Santiago de Cuba. It is very possible that the cable was broken owing to the recent hurricane at Turks Island, which travelled in a south-westerly direction. At the time of going to Press we also learn that telegraphic communication with Barbados has stopped owing to interruption of the two cables between St. Vincent and that island.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £63 to £63 10s. per ton (last week, £63 10s. to £64 10s. per ton).

BRYANT TRADING SYNDICATE.—The employees of the "Metalite" lamp department of the Bryant Trading Syndicate had their annual outing on Saturday last to Clacton.

ELECTRICAL TRADES' FOOTBALL LEAGUE.—The League will hold its first concert and presentation of medals on November 7th in the large hall at the Robertson Electric Lamp Works, Brook Green, Hammersmith.

GILBERT ARC LAMPS.—The Gilbert Arc Lamp Co. have appointed Messrs. Parmiter Hope & Sugden, of Hulme Electrical Works, 50 Ellesmere Street, Hulme, Manchester, to be their agents for Lancashire & Yorkshire, as from September 1st. Messrs. Parmiter Hope & Sugden will keep a large stock of the Gilbert standard apparatus, so that the ever-increasing number of orders for Gilbert lamps can be executed without delay.

"GRAL" METAL FILAMENT LAMP.—The Armorduct Manufacturing Co., Ltd., Farringdon Avenue, London, have secured the exclusive sale for Great Britain and the Colonies of the "Gral" high-voltage metallic filament lamp. The lamp is manufactured from 40 c.p. upwards; the size is considerably below that of any similar lamp at present on the market, being only 4½ in. by 2¾ in. overall, and the efficiency is 1 watt per c.p.

EXHIBITION AWARD.—The Union Electric Co., Park Street, Southwark, have been awarded a medal of the first class at the Camborne Mining Exhibition for their exhibit of motors, arc lamps, mining switchgear, and measuring instruments.

DISSOLUTIONS OF PARTNERSHIPS.—C. T. Brown and H. I. Lewenz, electrical and mechanical engineers, Romsey, Hampshire, have dissolved partnership.

The partnership between J. R. Middleton, Alfred Daniels, and F. W. Balch, carrying on business as electrical engineers, 11A King Street, Dover, as Middleton & Co., has been dissolved so far as concerns F. W. Balch, who retires from the firm.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—G. H. Smith, electrical engineer, 15 Ashley Road, Altrincham, has been adjudicated bankrupt. The first meeting of creditors took place yesterday at the Official Receiver's offices, Byron Street, Manchester, and the public examination takes place to-morrow at the Court House, Quay Street, Manchester.

A meeting of the Lancashire Electric Supply Co. will be held at 4 Chapel Walks, Manchester, on October 20th, at 3.30 p.m., to hear the liquidator's account of the winding up.

NEW PUBLICATIONS

"The Management of Dynamos." By G. W. Lummis-Paterson. Fourth edition. (London: Crosby, Lockwood & Son.) 4s. 6d.

"Electrical Engineers' Pocket-Book." By Horatio A. Foster. Fifth edition. (London: Archibald Constable & Co.) 21s.

The Telephone Tariff.—In view of the meeting of the Associated Chambers of Commerce at Cardiff, at which the question of telephone charges will be discussed, the following particulars of a correspondence which has taken place between Mr. Charles Lancaster, a member of the Telephone Committee of the Chambers of Commerce, and the Postmaster-General, is interesting. Mr. Lancaster asked the Postmaster-General whether a total of 10,000 outward telephone calls per annum, for a subscription of £10, could be contracted for by the Government to leave (*a*) a moderate profit, or (*b*) without loss. The reply of the Postmaster-General was to the effect that in his view such a tariff would certainly involve a financial loss, and, further, that 10,000 outgoing calls on a single line would overload it and seriously impair the efficiency of the service. In the course of a lengthy reply, Mr. Lancaster endeavours to show the kind of tariff that ought to be charged by the Government, by means of a very detailed statement, based upon the assumption that the National Telephone Co.'s system, as it stood on June 30th, 1908, was in possession of the Post Office. In this he eliminated those items which the Government would not be called upon to pay in the form in which they appear in the company's books, viz., royalties, income tax, pension fund, and compensation fund. The purport of the statement is that a tariff, under the measured rate system, should be capable of arrangement which would approximate to a subscription of £10 per annum for 10,000 outgoing calls. In his reply, the Postmaster-General expresses the opinion that, in existing conditions, 5,000 originated calls per annum made up a full load for the telephone line of an average subscriber who receives as many calls as he originates. At the conclusion of his letter, the Postmaster-General expresses his willingness, in the interests of the larger users, to consider a proposal on the lines laid down, which might lead to an equitable working arrangement.

THE RUBBER EXHIBITION AT OLYMPIA

THE International Rubber and Allied Trades Exhibition was opened on Monday last at Olympia. There are many exhibits of general interest, but few of particular interest to electrical engineers. Samples of various kinds and qualities of raw rubber from places all over the world are exhibited, and machines and photographs illustrating the different processes in the collection and treatment of the raw rubber and the operations of vulcanisation and compounding are to be seen. The Indiarubber, Gutta-Percha, and Telegraph Works Co., Ltd., have a large exhibit, which includes, among other things, pliers with ebonite covered handles, ebonite covered spanners, telephone cases, accumulator cells, switch-handles, and other ebonite and vulcanite productions. There is, of course, on this company's stand, also a good selection of sections of telegraph, telephone, power, and other cables, with both rubber and gutta-percha insulation. Messrs. Francis Shaw & Co., of Bradford, have several machines on exhibit, among which is one especially designed for grinding waste rubber. The rollers are of chilled cast iron, 28 in. long by 16 in. diameter. The caps are of solid forged steel, and the gearing throughout consists of machine-moulded wheels. The gearing is arranged to run the rollers at two speeds, the change being effected by means of a double clutch. The machine is motor-driven through double helical machine-cut wheels. A drum type starter is fixed on one side of the machine and an emergency switch above the rollers, so that in case of accident the whole machine can be stopped in a moment by pressing the button. Sections of electric cables, for both low- and high-pressure work are exhibited by the Société Industrielle des Téléphones of Paris, and a large number of books on rbuber and its applications are shown by various publishers. Messrs. Brooks & White have carried out the lighting of the stands, and the installation of the motors for driving the exhibits. The cable manufacturer who is interested in the origin and preparation of his raw materials should certainly pay the exhibition a visit, and we may mention that the catalogue issued by the Committee contains much valuable information on this subject.

MISCELLANEOUS CITY NOTES

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO.—A dividend of 4 per cent. per annum upon the ordinary shares has been announced.

BUENOS AIRES GRAND NATIONAL TRAMWAYS CO.—The *Stock Exchange Gazette* states that there is no longer any room to doubt that the time is not far distant when this company will be absorbed in the Anglo-Argentine system, and its capital shares exchanged for those of that concern.

CIA ANGLO-ARGENTINA DE ELECTRICIDAD.—The *Review of the River Plate* comments upon the fact that during the first year of its existence this company paid two half-yearly dividends, but that since October last no dividend has been paid, and that the shareholders are beginning to wonder what the company is doing in view of the fact that the other similar concerns pay regular interim dividends.

FELTEN & GUILLEAUME LAHMEYERWERKE A.G.—It is announced that this company has decided to increase their share capital from M20.000.000 to M25.000.000, and that the new shares will be offered to the existing shareholders. It is also proposed to issue M5.000.000 of 4½ per cent. bonds. The proceeds of these bonds will be employed in the redemption of the floating debt of the company.

NEWCASTLE & DISTRICT ELECTRIC LIGHTING CO.—The directors have decided not to pay an interim dividend for the half-year just ended.

ROBURITE EXPLOSIVES CO.—An interim dividend of 10 per cent. is announced per annum upon the preference shares.

APPOINTMENTS AND PERSONAL NOTES

Mr. V. A. Brown has resigned the sub-managership of the Grand National Tramway Combine (Buenos Aires), and, after a few months' holiday in England, will return to take up the General Managership of the Buenos Aires Lacroze Tramways Company.

Mr. A. C. Ellis, General Manager of the Metropolitan Railway, has resigned. Mr. R. H. Selbie, the Secretary of the company, succeeds Mr. Ellis.

Mr. C. D. Taite, the popular engineer and manager of the Lancashire Electric Power Co., was married on Saturday at St. Marylebone Parish Church, London, to Miss Eleanor Kathleen Corneille, fourth daughter of the late William Corneille, of Tipperary.

THE NATIONAL TELEPHONE EMPLOYÉS GRIEVANCES

As we go to press, an intimation reaches us to the effect that the Post Office does not regard as serious the complaint made by the National Society of Telephone Employés, with regard to the dismissal of some of the National Telephone Co.'s workmen at the end of construction work. It will be seen from the correspondence which we publish on page 437 that the Society is loth to give any very definite information as to the number of workmen of each class discharged, and the districts in which any wholesale dismissals have taken place, and that our request for precise figures in order to obtain an idea of the gravity of the situation has been replied to by a repetition of statements more or less of a general nature. The Post Office now say that the number of dismissals is not more than usual at the end of construction work. The announcement made by the department yesterday continues as follows:—

Employees, at all events, have nothing to fear as a result of the impending transfer to the Post Office, for this department is prepared to take over all employees who have been in the service of the company for a period of two years before December 31, 1911. Moreover, it is finding employment now for the temporary men who have been discharged. While the company cannot be expected, in view of the early transfer of their system, to do more than carry out the engagements already entered into, the Post Office has stepped into the breach and has taken over their obligations. It is constructing new lines every day, and is renting the wires to the company. For instance, the Post Office has built the new large exchange at Cardiff, and in several provincial towns it is laying down underground wires and performing work which otherwise would fall to the company. Thus there is no possibility of the telephone system's suffering in view of the position in which the company finds itself, and the lot of the employees cannot be greatly affected.

Further, the Post Office authorities have asked the permanent engineer of the company to let them know of any dismissals, in order that employment may be found for the men by the Post Office. Judging by the number of applications received, it is found that the number discharged is not more than usual. Naturally, the employees are afraid of losing their employment, and it is presumed that their fears are due to inaccurate statements. At present the Post Office is doing thousands of pounds' worth of work for the National Telephone Company, and before 1911 it is estimated that the Post Office outlay in this connection will exceed £500.000.

The inability of the National Society of Telephone Employés to furnish us with the numbers and status of unemployed in the various districts is therefore explained by the fact that the heads of the engineering departments of the Post Office and National Telephone Co. are in communication on the subject, with the result that re-employment of the capable men is already taking place, apparently without the necessity of any co-operation on the part of the Society.

BOROUGH POLYTECHNIC INSTITUTE,
103, Borough Road, London, S.E.

(Five minutes by Car from Blackfriars, Waterloo, and Westminster Bridges.)

ELECTROTECHNICS DEPARTMENT.

Head of Department:
JOHN HENDERSON, D.Sc., F.R.S.E., A.M.I.E.E.

First Year . .	General Principles (for Beginners).
Second Year . .	Technical Applications, including Electric Wiring and Fitting.
Third Year . .	Continuous Current Work: Instruments, Testing Dynamos and Motors.
Fourth Year .	Alternating Current Work, Principles and Theory, Measurements, Alternators, Motors, Transformers, Single and Polyphase Work.
Special Courses .	Electric Wiremen's Work, Construction and Design of Electrical Appliances and Workshop Fittings. Advanced Electricity and Magnetism.

Commencing 28th September, 1908.

For further particulars and detailed Syllabus of each Course, see Prospectus.

PUBLISHERS' ANNOUNCEMENT

On and after October 1st, the price of "Electrical Engineering" will be reduced to 1d.

The first number of "Electrical Engineering" was published on January 3rd, 1907, and the paper immediately took the leading position among the electrical newspapers. A thoroughly sound and practical technical paper, written and edited by men with long experience on the practical side of the electrical engineering industry, and illustrated with useful drawings to scale and well-printed photographs, was welcomed, and in spite of the comparatively high price of 6d., which it was necessary to charge for it, the paper scored an immediate success. The proprietors have been repeatedly urged to reduce the price in order to bring the paper within the reach of a wider circle of readers, and they are now in a position to make a concession in this direction that was not possible hitherto. They do not believe in half measures. On and after October 1st, therefore, "Electrical Engineering" will be on sale throughout the United Kingdom at the popular price of 1d. weekly (post free 1½d.), and it will therefore appeal to everyone connected with the electrical engineering industry. The leading features of the Paper will remain unaltered. No change has been made in the Editorial Staff, the same high-class printing and illustrations will be maintained, and the proprietors rely absolutely on the enormous increase of circulation which is assured, to recompense them for the sacrifice they are making in decreasing the price.

We feel confident that our readers will assist us by bringing the paper to the notice of engineers engaged in kindred branches of the engineering industry. It will be unnecessary, moreover, that

Digitized by Google

single copies of "Electrical Engineering" should circulate among 20 or 30 readers, as frequently happens at present; in future each reader will be able to buy and retain his own copy at 1d.

Arrangements have been made by which "Electrical Engineering" will be obtainable at all Messrs. W. H. Smith & Sons' and Messrs. Wyman's bookstalls, and through every newsagent in the United Kingdom. If any difficulty is experienced in obtaining it, complaint should at once be made to the Publishers. Readers who prefer to receive the paper through the post should order it direct from the Publishers (The Kilowatt Publishing Co., Ltd., 203-6 Temple Chambers, London, E.C.). The annual subscription rate, including postage, is 6s. 6d. for the United Kingdom, 8s. 8d. for Canada, and 13s. for other Colonies and abroad. (Subscriptions should be paid in advance.)

Existing subscribers will have the unexpired period of their subscriptions extended in proportion to the difference in price.

WE regret to say that Messrs. Cassell and Co. Ltd., are issuing in sevenpenny fortnightly parts a publication entitled "Electrical Engineering," in spite of our protests that confusion is likely to arise in the newspaper trade owing to the title being the same as ours. Particulars of this serial appear in our advertisement pages. There is no possibility of any of our present readers being misled, but to avoid mistakes by their newsagents they are recommended to make it clear when ordering their copies that they require "Electrical Engineering," the weekly newspaper.

SUMMARY

WE are now able to give some further information as to the report of Mr. C. H. MERZ on the electrification of the Victorian Railways, supplementing the brief outline of the proposed scheme in our last issue. The system recommended for the lines, which are principally suburban, is a protected third rail at 800 volts, with power taken from a large steam turbine-driven generating station, transmitting at 10,000 volts three-phase to rotary converter sub-stations. An acceleration of 0·92 mile per hour per second is recommended, and the trains are to be made up of standard units, each consisting of one motor coach, with two motors on one bogie, and one trailer. The whole net capital cost of the conversion, which is to be taken in hand in four stages, is estimated at £1,801,460, and the operating expenses per train mile are estimated as 11·03d., as against 18·93d. for steam traction. (Page 451.)

Two new patterns of automatic switches for indicating, by flickering or total extinction of the light, when a consumer's demand has exceeded the maximum permissible according to his contract, have been recently put on the market by two well-known German firms. The first type operates by the action of an electromagnet on a swinging balance wheel, to which is attached the main-switch arm, and the second makes use of the expansion of a stretched wire in series with the load. The former pattern produces flickering of the lamps, the latter intermittent extinction every few seconds. (Page 456.)

THE seventh annual conference of the Municipal Tramways Association commenced yesterday, with Mr. J. ALDWORTH'S presidential address, in which he reviewed the year's work of the association and touched on a number of tramway problems awaiting solution He said he was watching with interest the development of the trackless trolley system, which he hoped would prove a valuable factor in the extension and linking-up of tramway systems. A Paper was also read by Mr. H. E. BLAIN on through-running, in which the advantage of its adoption wherever circumstances permitted, was urged, and particulars were given of the methods adopted in a number of actual cases, including the author's own system at West Ham. (Page 457.)

A LETTER from Mr. MILES WALKER answers some of the criticisms on his proposed scheme of new physical symbols. (Page 458.)

A LARGE "superfine" spinning mill, newly-built at Bolton and shortly to be put in operation, has been constructed from the outset with electric driving. A detailed description gives full particulars as to the arrangement of the motors, and it also includes a detailed description of the 400 kw. Zoelly turbine used in the power-house. (Page 459.)

A FIRE occurred at the main Paris Telephone Exchange between 8 and 9 o'clock on Sunday evening, which resulted in the whole of the centre of Paris, on the right bank of the river Seine, being cut off from telephonic communication. By yesterday, however, communication had been re-established with London and Brussels, as well as with a considerable number of French towns outside Paris. (Page 464.)

A DEMONSTRATION of a system of wireless operation of the keyboards of Linotype or other machines was given in London on Thursday last by the inventor, Mr. HANS KNUDSEN. The apparatus consists essentially of two travelling brushes moving synchronously over a row of contacts at the transmitting and receiving stations respectively. The system is not yet sufficiently developed for practical working. (Page 465.)

A NEW form of double tumbler switch has been introduced. (Page 465.)

THE new engineering laboratories and workshops of the Heriot-Watt College, Edinburgh, were formally opened by Lord Rosebery on September 16th. The laboratories are devoted entirely to mechanical engineering and include steam and gas engine plants specially designed and arranged for experimental purposes. The metal and wood-working tools in the workshops are electrically driven. (Page 467.)

THE report of Colonel YORKE and Mr. TROTTER on the fire which occurred on the City and South London Railway in July states that the actual origin of the fire cannot be ascertained with certainty, but the opinion is expressed that it probably did not originate from any defect in the insulation or continuity of the cables, but began with a smouldering which may have developed into flames by the draught of passing trains. Some recommendations are made with a view to reducing the risk of fire or smoke, especially as regards the more complete removal of dust and dirt. The section of the line where the fire took place was opened before the present Board of Trade regulations regarding tube railways were in force. (Page 468.)

MAJOR PRINGLE'S Board of Trade report on the Bournemouth tramway accident attributes the running away of the car to a defect in the rear controller unknown to the driver, which prevented the magnetic brake from acting when called upon. Major Pringle also severely criticises the management of the undertaking. Some letters from the officials of the tramways refute his criticisms. (Page 469.)

THE economies obtainable by the adjustment of the load of electrochemical works to fill up the inequalities of the load curve of central stations are discussed under

ELECTROMETALLURGY and ELECTROCHEMISTRY. The electrolytic refinery at the San Francisco mint is also described. (Page 472.)

A PATENT relating to the construction of polyphase motors for marine propulsion was published by the Patent Office on Thursday last. This was granted to H. A. MAVOR and MAVOR & COULSON, LTD., and is for a method of building the motor into the framework of the ship for the purpose of saving weight. Among the other specifications published is one by O. SCHALLER for a train lighting system, which consists in making the lighting pressure the sum of the voltages of two generators, the speed of one of which drops as the speed of the other rises. A double suspending hook for metal filaments, by which the sides of a loop are prevented from touching, has been patented by the DEUTSCHE GASGLÜHLICHT AKT.-GES., and a specification by J. W. HUNTINGTON describes a combined wall-plug and switch. The specifications of H. C. E. JACOBY for the single-phase variable-speed motor, recently described in these columns, have also been published. A specification by E. L. OPPERMANN relates to an improved form of case for accumulator cells. The BRITISH THOMSON-HOUSTON Co. have one for a method of cross-connecting the armature windings of high-speed direct-current machines, whereby the voltage per segment is considerably reduced without, it is said, any detrimental self-induction, due to the cross-connecting conductors, being inserted in the coils. A patent granted to THE HALL SIGNAL Co., U.S.A., for a motor-operated railway signal, expires during the current week. (Page 473.)

THE Belfast Corporation is not sending official delegates to the Municipal Tramways Conference in Nottingham, owing to the Local Government Board having surcharged the expenses of the Corporation delegates to the Municipal Electrical Association this year.—There is a net loss of £358 upon the Kilmarnock electrical undertaking for the past year, and a deficit of £1,852 upon the tramways undertaking.—Surveys are being carried out in connection with the Euston-Watford electric railway.—An independent expert is to be engaged by the West Ham Corporation in connection with the Local Government Board inquiry for a new loan.—The Board of Trade have refused to insert a clause in the York Light Railway Order giving the Corporation power to sell the undertaking.—The Chairman of the Bray Electric Lighting Committee has resigned owing to the lack of interest taken in the undertaking by other members of the Council.—In reply to an inquiry from the Dundee Council, the Board of Trade state that they have no *prima facie* objection to electric trolley omnibuses.—There was a loss of £1,789 upon the Ipswich Electric lighting undertaking for the past year, and a loss of £1,450 upon the tramway undertaking. (Page 475.)

TENDERS are invited by the Watford Council for generating plant; a 200 h.p. induction motor is required by the Birmingham, Tame, and Rea Drainage Board; London County Council advertises for fuel economisers, feed-pumps, and two 5,000-kw. horizontal steam turbo-generators. Local Government Board inquiries have been held as follows:—Holyhead (£3,000); Stoke (£15,365); Maidstone (£18,440). Switchgear is required by the Radcliffe Council. (Page 476.)

THE accounts of Messrs. Dick, Kerr & Co. for the year ended June 30th show a gross profit of £125,867. The dividend upon the 6 per cent. preference shares is recommended, and 10 per cent. upon the ordinary shares. A dividend for the June half-year of 1s. 7½d. is declared by Messrs. Babcock & Wilcox. (Page 478.)

MR. R. NELSON, of Messrs. Merz & McLellan, has been appointed to the newly-created post of H.M. Electrical Inspector of Mines. (Page 479.)

THE electrical equipment of the Victorian railways is an important scheme, and we are glad to be able this week to publish some additional information with regard to Mr. MERZ'S project, supplementary to the brief description we gave last week from a condensed official abstract of his report. We have now been privileged to see a copy of the full report, and have been able to gather some additional particulars. In the first place it is now clear that the total length of 124 route miles, which it is proposed eventually to run electrically, consists of several lines, radiating more or less from a centre, and all of an essentially suburban character. The area of distribution, therefore, is by no means too great to reach from one power house on the high-tension three-phase system with converting sub-stations, and the total power required—estimated at about 35,000 h.p.—is not unduly large for a single generating station when compared with the totals estimated in the most recent London power schemes. Mr. Merz's recommendation to use a D.C. third rail system is also quite intelligible when the conditions are properly appreciated. As we have said, the system is a suburban one—a system with heavy passenger traffic and no goods traffic—one to be run with motor-cars on the multiple unit system rather than with locomotives. To apply an alternating-current system for this would entail not only extra weight but extra complication, the addition of transformers on the trains, and the employment of motors on more of the axles. A continuous-current third-rail system on the other hand, would be largely on standard lines of design, and notwithstanding the campaign against this system a few years ago, there can be no doubt that it is possible to protect the third rail adequately in such a way that danger can be avoided. In fact, it is not even necessary to go so far as to use an "under-running" system; the ordinary third rail protected by boards on both sides should be quite sufficient, and we believe that no accidents have been recorded for rails guarded in this manner. If, however, an under-running system is regarded as a *sine quâ non*, Mr. Merz offers an alternative to the New York rail, which is worthy of serious consideration. Finally, we would call attention to the acceleration question that has recently become almost too much of a fetish. That rapid acceleration is desirable on suburban lines is a doctrine which must, of course, be accepted, but it is possible to go too far in this direction. A point is reached at which one can pay too much for this, and it must be remembered also that there are suburban lines and suburban lines, and that the conditions of the London tube railways are not reproduced everywhere. In considering this question, and also the question of A.C. *versus* D.C., it must be remembered, moreover, that the cost of power is only one item in the cost of running a railway; the cost of maintenance is, in most cases, of equal importance. To gain a slight economy in energy consumption by adding to the equipment of each train, is bad policy if the total amount of inspection and repairs is increased in greater proportion. We are unable to publish Mr. Merz's report in full, as it fills a large volume, and the account of it we give on another page is necessarily somewhat condensed. In giving consideration to the subject, however, the points we have mentioned should not be overlooked.

DUST, of sorts, is officially declared to be the cause of the fire near Moorgate Street Station on the City and South London Railway on July 16th, as will be seen by the report of Col. Yorke and Mr. Trotter, which we publish on another page. The dangerous character of combustible dusts, especially those of coal, flour, cotton-seed, and linseed, has been abundantly verified during recent years, and it is recognised that their safe removal is as important as that of inflammable gases or vapours. But that the dust which gathers in a tube railway should constitute a fire risk is rather surprising. The two constituents specifically charged with this property are iron from the brakes, rails, and wheels, and carbon from the motor brushes. Incidentally, it may be mentioned, that on the newer tube railways in which the schedule speeds are higher and braking consequently more powerful than on the City and South London, iron dust has given so much trouble by causing leakage over the insulators that compressed treated cotton brake blocks are being tried as subsitutes for iron. The rusty appearance of the sleepers in the open stations on the District Railway in wet weather reveals the large quantity of iron dust produced. Finely divided iron requires a high temperature to ignite it, and, moreover, it is somewhat surprising that it should remain unoxidised for a sufficient time to remain in appreciable quantity as metallic iron on sleepers and cables. Carbon dust should be present, only in much smaller quantity than iron. Oil or grease mixed with the dust, however, will greatly increase its inflammability and promote the maintenance of combustion, and as practically all the lubricant used on the railway is finally distributed on and about the track, and the quantities are much in excess of the brake blocks and brushes used up, we are disposed to suspect this as the chief culprit. Sparks from a collecting shoe, or creeping leakage over an insulator, may have ignited the greasy dust, and there is good evidence that no cables failed until burnt through from outside. The incident will, doubtless, result in greater attention to cleanliness on tube lines, and to a rigid avoidance of combustible materials and open spaces between the sleepers, although the recently constructed tube lines are open to little improvement in this respect. In this, as in every other tube or tunnel fire, smoke was the dangerous element. It drove off the railway men and prevented the firemen reaching the fire for nearly two hours, and yet the actual damage done and amount of stuff burnt was quite small. It is a matter of congratulation that no loss of life or limb resulted, and that the City and South London Railway retains its reputation for safety.

MAJOR PRINGLE'S report on the disastrous runaway car accident at Bournemouth on May 1st shows the primary cause to have been an electrical fault which put the magnetic brake out of action. The controller defect is of the same character as that which led to a recent accident at Glasgow, and was hardly recognised as a possible cause of brake failure until Colonel YORKE investigated that accident. There will be no excuse for overlooking it in future. Beyond the particular cause, the Bournemouth case is additional evidence to the weak points of the magnetic brake, viz., its dependence upon a complete electrical circuit through a large number of contact points, some in parallel, and the absence of any indication of failure until the brake is wanted. On long or steep inclines where the coasting brake is essential to safety, the risk of brake failures must be removed by the adoption of the most certain appliances. In the Bournemouth case the car worked over a route with several long descents, perfectly safe to work with a reliable brake, but entirely dependent on the brake for safe working. The gradient on which the runaway took place is not very steep, but it is capable of giving an unbraked car a speed of 40 miles per hour by the time it reached the point of derailment. The driver, unfortunately, did not recognise the failure of the magnetic brake until it was too late to control the car with the hand-brake, but he stuck to the car, did his best, and was badly hurt, so he escapes censure. The management of the Bournemouth tramways comes in for the inspector's criticism. He regards it as a capital error to run a tramway system without a chief officer, responsible for the whole conduct of the undertaking, an error that would appear to be committed by a considerable number of municipal authorities. He also condemns the practice of sending a car to different sheds, so that it is impossible to say that a particular man is responsible for failing to observe a defect. We are afraid that the traffic manager's notion that this system excites emulation in the discovery of faults is based on a too partial estimate of human nature. Emulation could be better maintained between the different sheds by recording and publishing to the men periodically the car miles run per stoppage on the road by the cars belonging to each shed.

Electrification of the Berlin Stadtbahn.—According to *Elektrotechnik und Maschinenbau*, the conversion of the Berlin Stadtbahn to electric traction will be commenced shortly. The total cost of electrification is estimated at 180 million marks (approximately £9,000,000). The *Elektrotechnischer Anzeiger* states that the plans for the electrification have been drawn up entirely by the Berlin railway authorities, with the exception of the cost estimates, for which the assistance of the large electrical firms was allowed. Two new pairs of rails are to be laid adjacent to the existing double track, and on each of the two tracks for the one direction, a two-minute service will be run; this gives a one-minute service in either direction, which is three times as good as the present service. The total length of single track to be electrified amounts to over 300 miles, including the Stadt and Ringbahn and the suburban railways. It is proposed to connect the Potsdam and Stettin stations on the suburban railways by an underground line. An increase in the tariff to help to cover the expenditure is expected.

Manchester Exhibition.—Following the policy adopted at the Olympia Exhibition in 1905, the management of the Manchester Electrical Exhibition has decided to arrange for a series of lectures on electrical and allied subjects to be delivered by well-known authorities during the holding of the Exhibition. Complete details, however, are not available at the moment. Among the other many attractive features of the Exhibition will be working exhibits showing the processes of incandescent lamp manufacture. In this, the Olympia Exhibition of 1905 will also be followed, there being two such exhibits on that occasion. Arrangements are also well advanced in connection with the model home, in which the latest developments of electricity to domestic necessities and luxuries will be effectively demonstrated. We understand that this home is to be inside the Exhibition buildings, and not, as was at one time proposed, in the grounds. In order to obtain the fullest possible effect, at all times in the day, from the electric lighting exhibits, the building has been so arranged that daylight will be to some extent excluded, and artificial light principally relied upon for its illumination during the day time. Facilities for telephonic communication are to be available in the building.

THE ELECTRIFICATION OF THE VICTORIAN RAILWAYS

WE gave in our last issue a short summary of the long report which Mr. C. H. Merz has submitted to the Victorian Railway Commissioners on the proposed adoption of electrical working on the railways in the neighbourhood of Melbourne. We have now had an opportunity, through the courtesy of the Commissioners, of seeing the complete report, and are able to give some more extended information as to its contents.

The primary object of the report is to determine whether the substitution of electric traction for steam traction on the Melbourne suburban system is financially justifiable. This involves a decision as to how, from an engineering point of view, such a change should be carried out, and the consideration of the advantages it offers the public.

In the introductory letter Mr. Merz points out that the steady growth of the suburban traffic will make it necessary for the railways to provide additional facilities before very long, in any case, and the present is therefore a good time for examining the possibilities of electric traction. So many heavy suburban lines in Europe and America have been converted to electric traction that there is nothing experimental about the present proposal, and the results obtained on these other systems enable a pretty close estimate to be made of the results obtainable in Melbourne.

The report analyses the nature of the traffic on the railways under consideration and shows how the Melbourne suburban system is a very much more important part of the railway system as a whole than is the case in most great cities.

A general map showing the extent of the suburban system is given in Fig. 1.

In considering the general advantages to be obtained by the substitution of electric for steam traction, it is pointed out that electrical operation necessitates a higher capital expenditure than steam operation, but it gives a considerable saving in operating expenses and many other advantages, of which the principal are as follows :—

From the Public Point of View.—Regular and more frequent service throughout the day. Greater punctuality, due to the greater ability of an electric train to make up lost time. General improvement in the smoothness and safety of working, due to the automatic controlling devices whose adoption usually accompanies electrification. Prevention of fires on property adjacent to the line arising out of sparks from locomotive uptakes. Practical abolition of smoke, steam, and dust, and a great reduction of noise. Possibility of shortening the time of journeys below anything possible with steam. Improved lighting and cleanliness of carriages and stations. Satisfactory regulation of the heating of coaches.

From the Railway Manager's Point of View.—Higher schedule speed, enabling a larger mileage to be obtained from a given amount of rolling stock and a greater number of trains to be operated over a given length of track. Continuous and regular movement of trains, and, in consequence, more economical employment of train crews. Greater

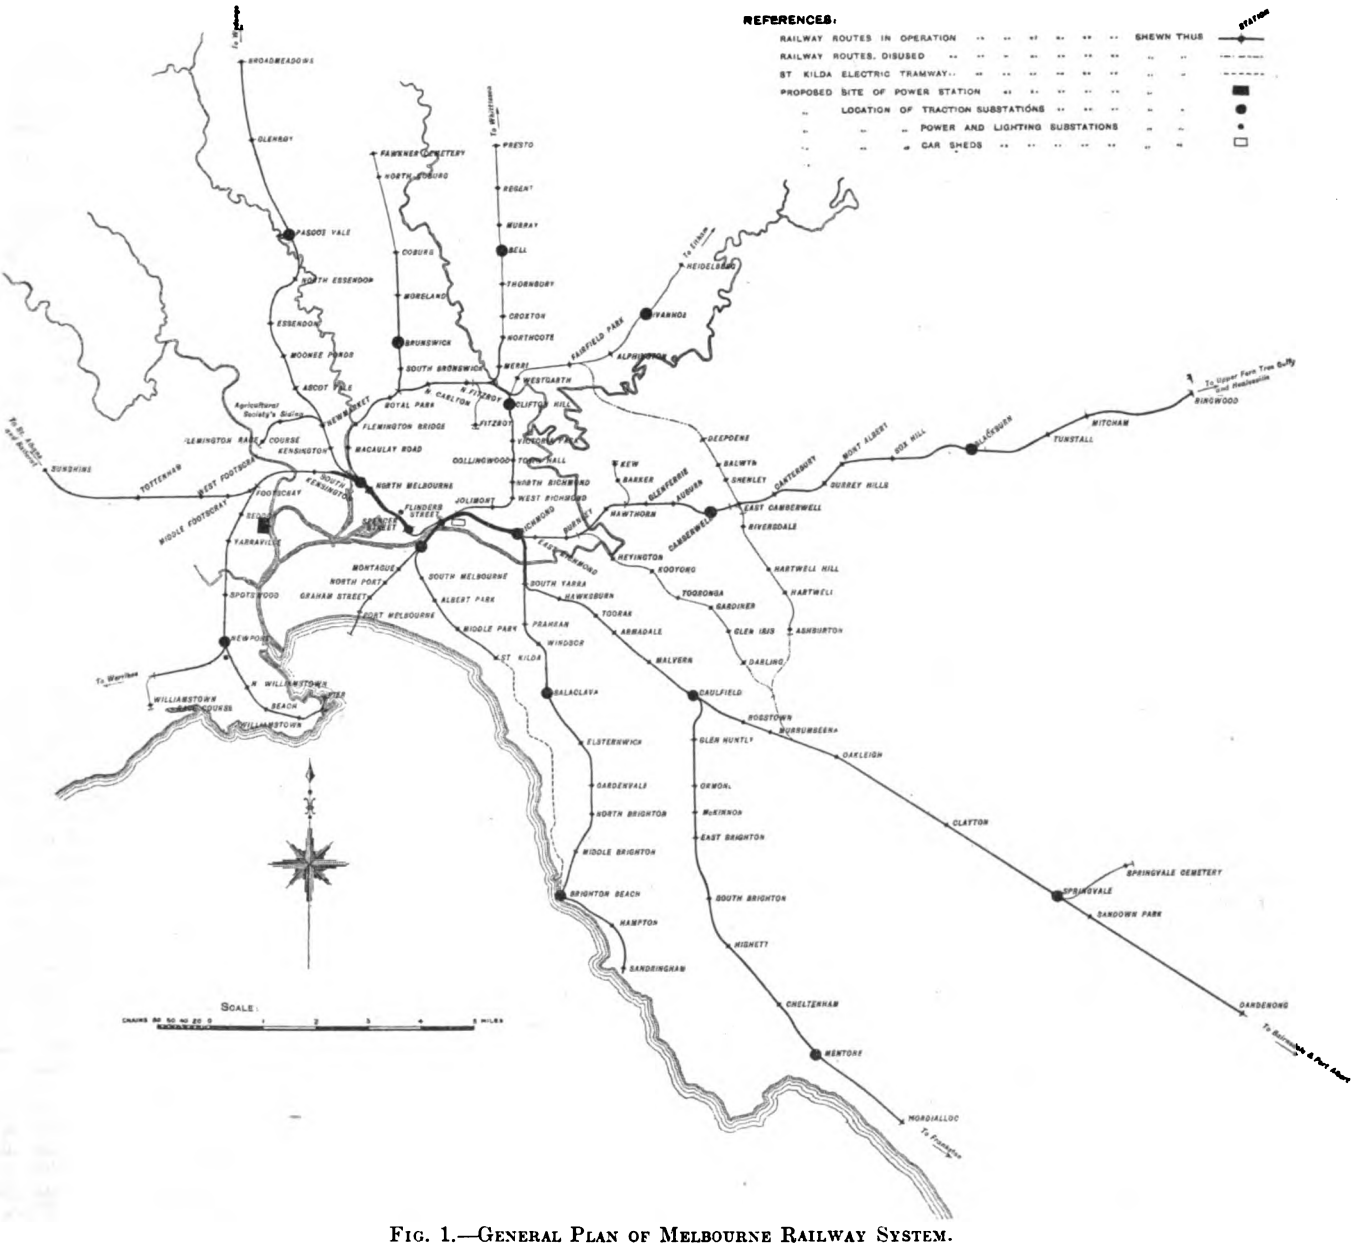

FIG. 1.—GENERAL PLAN OF MELBOURNE RAILWAY SYSTEM.

Digitized by Google

flexibility in making up trains to meet the varying requirements of the traffic, both throughout the day and on special occasions, such as race days. Ability to reverse trains at termini immediately without engine shunting, thus reducing the time wasted, the tracks occupied, and the signal and point movements, and entirely dispensing with shunting locomotives, and in consequence (assuming the adoption of the multiple-unit system) increase in capacity of termini, and postponement of terminal extensions. Elimination of the lighting up of locomotives, and of the inefficient water, coal handling, auxiliary, lighting, and heating appliances. Use in the power station of a cheaper fuel than can be used in locomotives. Supply of electric power at a low price available for a number of purposes, such as railway workshops, cranes, and capstans, for which an independent installation would not be justifiable or economical. Reduction in repairs and an increased life of track due to the weight of the driving machinery being distributed throughout the train instead of being concentrated, as in the steam locomotive. Reduced cost of painting, and increased life of metallic structures near the railway due to absence of corrosive fumes.

From the Profit Point of View.—Reduction of operating expenses even for the same train mileage, and considerably greater saving in the expenses per train mile when the mileage is increased. Increase of revenue due to an increase of traffic. Improved earning power of capital sunk in lines, stations, and rolling stock, due to the increased traffic capacity, thus saving capital expenditure which would otherwise be necessary to meet growth of traffic.

The question of acceleration is dealt with. The average length of run on the Melbourne system is five-eighths of a mile, and the average time taken rather more than 2½ minutes. With electrical operation it would be possible to accelerate the trains much more rapidly than with steam, and reduce this to about two minutes.

Numerous attempts have been made on other railway systems to obtain high acceleration with steam locomotives, but it has not been very satisfactory. In actual operation it is usual to take advantage of the high acceleration possible with electric traction, and for economy's sake to accomplish as much as possible of the run by coasting. It is always possible in emergency, as when it is desired to make up time, to cut down coasting and keep the current on until the brakes are applied. The present schedule speed of the Melbourne system averages about 16 miles an hour, and with electric traction it is proposed to increase it to 20 miles an hour. A table is given to show how these figures compare with other railways of varying lengths and average distance between stops. On the Pennsylvania Railway (West Jersey), a line 160 miles in length with an average distance of 8,800 yards between stops, the schedule speed is given as 28·8 m.p.h.; on the Liverpool Overhead (13 miles and 670 yards between stops), it is 19 m.p.h., and the figure for the Central London Railway, of the same length, with 840 yards between stops, is 14 m.p.h.

The acceleration recommended to attain the desired result with sufficient margin for making up time is (on the level) 0·92 miles per hour per second, that is, 1·35 feet per second per second. In determining this figure for acceleration a number of considerations were taken into account, and calculations were made as to the effect of varying the accelerations upon the power consumption, and some curves are given in this connection. A study of these shows that the gain in economy by raising the acceleration above one mile per hour per second is comparatively small for the schedule speed chosen, whilst the increased consumption of electricity, if an acceleration of less than 0·8 be chosen, is very marked indeed. Another important consideration was the margin of speed at the disposal of the driver for making up lost time on different lengths of run. A large collection of speed curves worked out for the actual conditions, with a motor and control equipment designed for the above acceleration, with the weight of train proposed, accompany the report.

It is unnecessary to recapitulate the advantages of the multiple-unit system as given in the report, as they are now universally recognised for this class of work. The normal train recommended by Mr. Merz for Melbourne would be made up of an equal number of motor and trailer coaches; that is to say, the unit is a two-coach train. On outlying routes, of course, the traffic will sometimes be dealt with by a single-coach train, but on busy routes, especially at morning and evening, the trains will consist of two, four, six, or eight coaches. Except where arranged to operate only in four- and six-coach trains on the heavy sections of the system, the trailer coaches will be provided with a driving cab; all motor coaches will be furnished with at least one driving cab.

There follows in the report a detailed exposition of the time-table which it is proposed to adopt, and in framing this attention has been devoted to the desirability of keeping a uniform and frequent service throughout the day, and for economic reasons of encouraging traffic during the slack hours.

The relative merit of various systems of electric traction were very fully gone into before the final recommendations were arrived at, including "third-rail systems" with low or high pressure direct currents, and overhead systems with high pressure direct current (1,200 volts), three-phase at 3,000 volts or over, and single-phase at 6,000 to 10,000 volts.

As the investigation proceeded and the conditions to be met with on the system were fully realised, it was considered that all the systems might be put on one side with the exception of the unprotected third-rail system, the protected conductor rail system, and the single-phase overhead-wire system.

The calculations show that a protected conductor rail system with a voltage of 800 has many advantages over the unprotected third-rail system at a lower voltage, from both financial and operation points of view. Although the unprotected third-rail system has been operated with great success both in England and abroad, and although the accidents from shock have been remarkably few even in a country like England, where for a large part of the year the ground is more or less saturated with moisture, there is no doubt as to the superiority of the protected conductor rail system even in a climate like that in Melbourne. When in addition it is found, as is here the case, that an 800-volt protected conductor rail system can be installed for considerably less money, and will operate at a higher efficiency on account of the lower losses in the conductor rails and track, Mr. Merz has no hesitation in recommending it in preference to any unprotected third-rail system, even under the particularly favourable conditions of track and climate existing in Melbourne. For the Melbourne suburban railways, therefore, it comes down to a choice between the 800-volt direct-current protected conductor rail system and the single-phase overhead-wire system.

It has been claimed that even for such suburban railways on which there is a frequent service, the single-phase system shows very considerable advantage in first cost compared with the direct-current system. This, however, has not proved to be the case after having worked out in detail the cost of dealing with the Melbourne suburban traffic, for not only would the overhead lines be very much more costly than has frequently been stated to be the case, but the additional cost of the large number of train equipments required would practically balance the extra expenditure on the sub-stations required in the case of the direct-current system; in fact, the very complete investigation which was made into the first cost of providing the electrical equipment for the Melbourne suburban railways has confirmed the opinion as to the relative first cost of the two systems which Mr. Merz had formed in investigating similar problems for the other suburban railways. In the case of Melbourne, it is only when including very long and sparsely populated lines, such as the Frankston Branch, to which in any case Mr. Merz does not consider the extension of electrical operation justifiable, that the single-phase system shows any appreciable saving in first cost over the direct-current system.

However, when coming to consider the total annual cost (which is the important figure), including operating expenses and interest charges, it is found that under Melbourne conditions the direct-current system shows a saving compared with the single-phase system. It is, therefore, not found possible to recommend the adoption of the single-phase system on financial grounds.

As, therefore, Mr. Merz cannot recommend the Commissioners to consider the single-phase system for financial reasons, and as he considers that the direct-current system is superior to it in a case such as that of the Melbourne suburban railways from an operating standpoint, he has decided, after having studied the whole problem in great detail and from all points of view, that the direct-current 800-volt protected conductor rail system is the right one to adopt for Melbourne.

As a mechanical structure a protected conductor rail, compared with overhead wires, is superior in both simplicity and reliability; it not only needs less repair, but less inspection. Most important of all, the inspection and repair work can be done by the ordinary permanent way staff in daylight, and when the service is in full operation, whereas the inspection and repair of overhead wires requires a special staff, not only because it has to be done at night, but also on account of the class of labour required. This is obviously very important in a country where electrical operation has not hitherto been adopted and where labour is dear. When it is also considered that the wear on the conductor rail is practically negligible, whereas the wear on the overhead wire is not inconsiderable, this point becomes still more important. While overhead wires may be in every way suited to long lines on which the service is not so frequent and where there is consequently less wear and tear, and where, also, there may be time between trains to inspect and to do repair work, the protected conductor rail, which needs less inspection, and can be, and is, inspected at any time by the ordinary permanent-way men, offers a more reliable service on a busy suburban system.

The question of interference with the important telephone system of Melbourne, although not a matter which concerns the State so much as it does the Commonwealth Government, might have justified, Mr. Merz considers, the taking into consideration—though this has not been done—of the large extra expense which the installation of high-tension overhead wires closely adjacent to the telephone wires would probably mean, not to mention the great public inconvenience of having the telephone service seriously interfered with even temporarily.

On the basis of 83·7 watt-hours per ton mile (which includes allowances for lighting, heating, control circuits, make, compressors, &c.), it was estimated that the maximum E.H.P. required from the power station for the Port Melbourne and St. Kilda branches—which, as stated in our last issue, is the first instalment proposed for conversion—would be 1,920, and that the whole scheme would call for a maximum of 32,100 E.H.P. Allowing, therefore, also for an extensive power and lighting scheme, the total maximum demand is put initially at 3,480 E.H.P. with a load factor of 34 per cent., and ultimately, on the completion of the third stage, at 35,000 E.H.P. As there are no existing power schemes of a nature suitable for the supply of the large amount of power required, there is no alternative to the construction of an entirely new generating station.

The question of coal and water supply is fully dealt with, and after discussing the relative possibilities offered by stations near the railways and in the Victorian coalfield district, a site for the power station is recommended at Yarraville, where seaborne coal from New South Wales can be unloaded, or Victorian black or brown coal obtained by train. This site is satisfactory as regards water supply, and is within three miles of the centre of the system. A plan of the proposed station is given in Fig. 2. For its equipment the steam turbine has been chosen as being the most efficient machine for producing power with large variations of load, and possessing advantages over the reciprocating engine in steam consumption, attendance, oil, and repairs. With regard to the possibility of using gas engines, Mr. Merz writes as follows :—

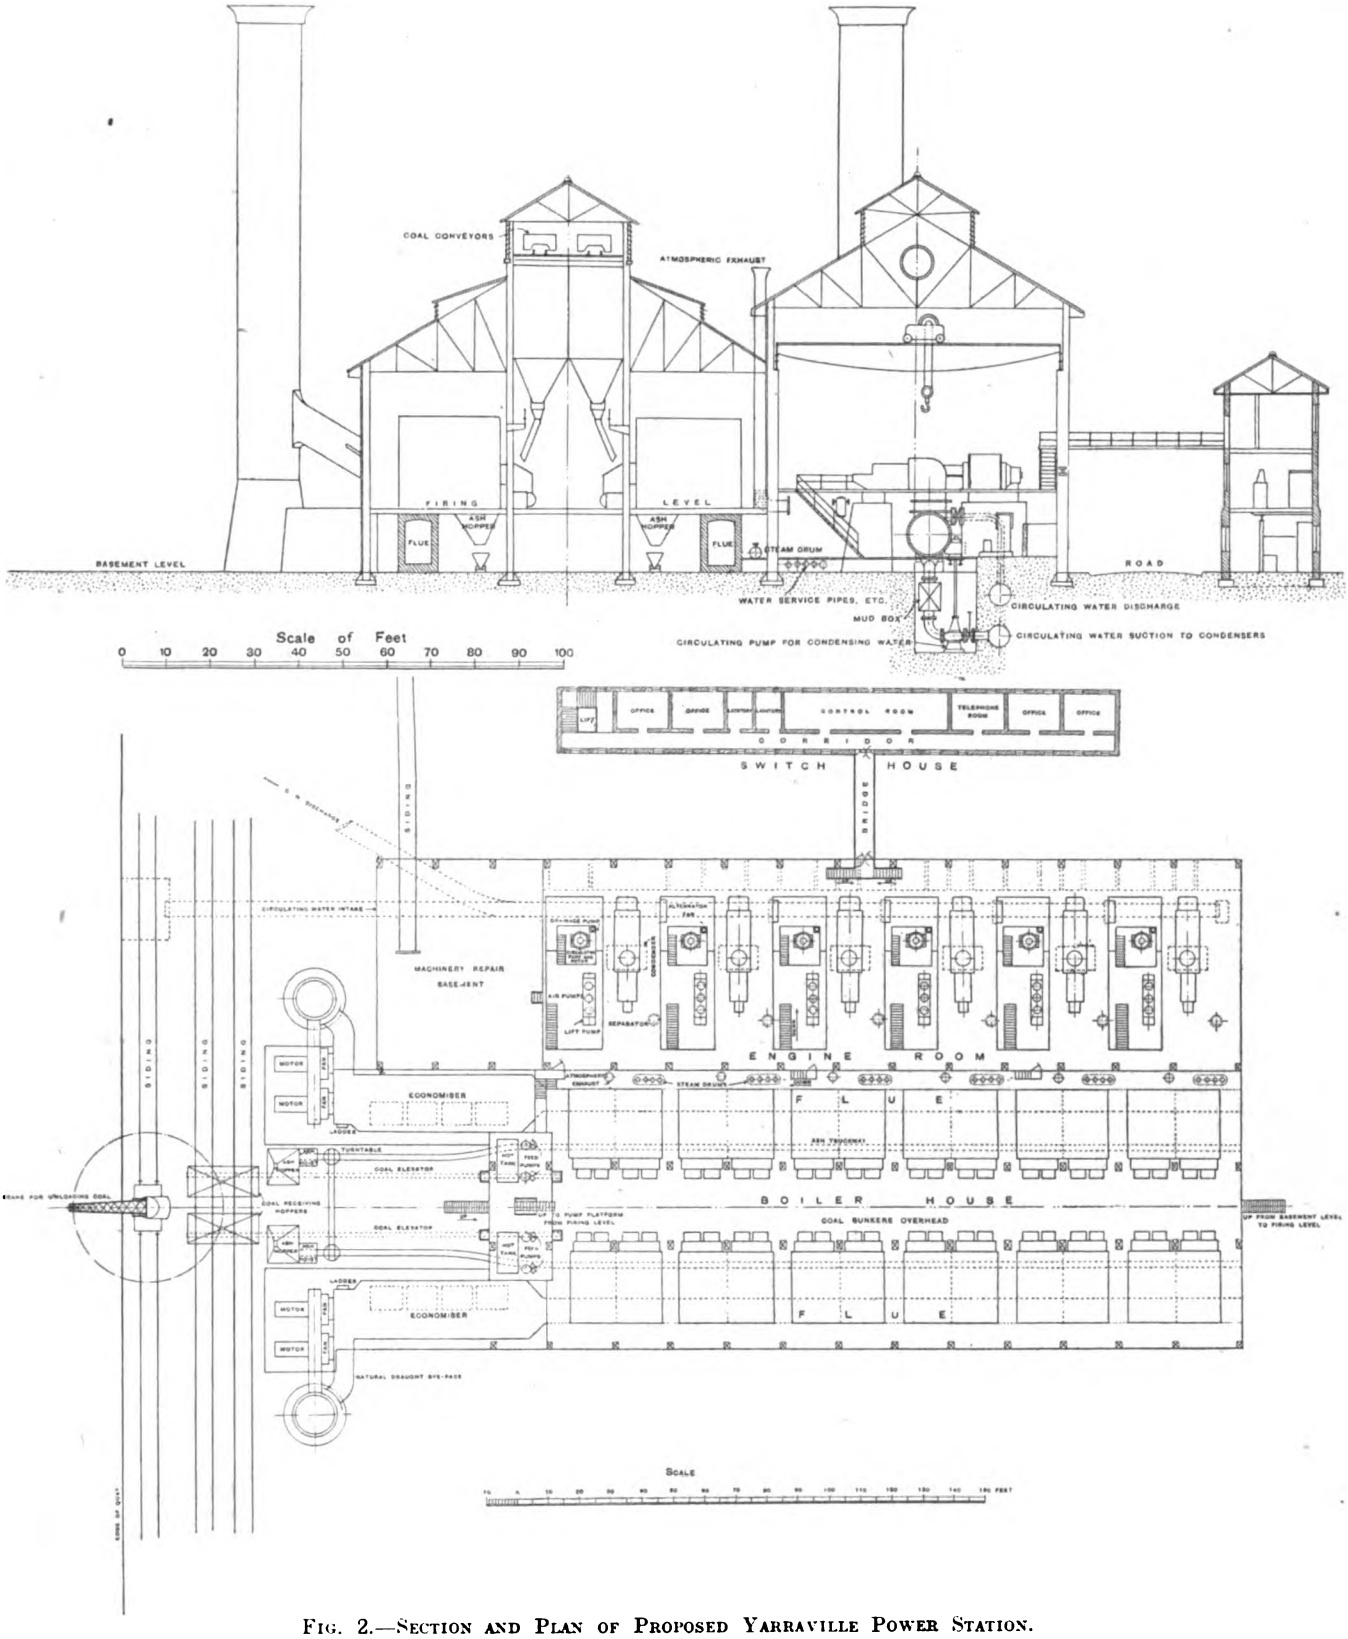

FIG. 2.—SECTION AND PLAN OF PROPOSED YARRAVILLE POWER STATION.

Digitized by Google

"Though gas engines might be considered for dealing with a load which resulted in a much better load factor on the station, 70 per cent. to 100 per cent., and which had not the same momentary variations, they could not, on account of the absence of overload capacity, deal with a load such as that now under consideration without very excessive capital expenditure. This is the position to-day and is likely to remain the position for some considerable time. In saying this I have fully in mind the possibility of saving and disposing of the by-products if gas were utilised."

The station is designed to deliver three-phase current at 25 cycles per second at a voltage of 12,000 volts. This voltage was chosen as the highest for which turbo-generators could be recommended, and is sufficiently high for economical transmission to the various sub-stations. The buildings will be steel-frame structures caried on concrete foundations, and the coal will be delivered to coal bunkers situated above the boilers by automatic coal conveyors. The engine-room will contain turbo-generators each of a capacity of 6,000 horse-power. This size of turbo-generator was chosen because it is about the maximum size of alternator that can be built conveniently for 1,500 revolutions, the highest speed for which a 25-cycle generator can be built. In order to deal with the first stage of conversion of the lines, four generating sets will be put down, two of which will be easily able to deal with the load, thus allowing two generator sets as spares. Mr. Merz emphasises the fact that it is advisable to have two spare sets in order that the one set may be standing by while the other is overhauled.

The station can readily be extended for any number of units that may be required from time to time, though the intention is that it should not be extended beyond a total of 10 units. The boilers will be of the water-tube type, delivering steam at a pressure of 200 lb. per sq. inch superheated to 300° C.

A special feature of the design will be that the switchgear from which the operation of the machinery and the circuits will be controlled, will be situated in a separate building, where the operators are undisturbed by the noise of machinery or accidents. An elaborate telephone system connects this control room with each engine, and also connects it with the various sub-stations throughout the system to which the high-pressure current is conveyed, and where it is transformed into low-pressure current suitable for use on the trains. These sub-stations vary in capacity from 1,500 to 6,000 kw., and for the complete scheme would be sixteen in number.

With regard to the transmission of current to the sub-stations, estimates are given for various alternative arrangements for cables throughout, for overhead lines, and for a combination of the two, which on the whole is considered preferable. The proposed equipment for the sub-stations includes rotary converters, and does not call for special remark.

The collection of current from the conductor rail is to be by means of a contact shoe attached to the bogie truck, and this may be of either the under-, over-, or side-contact type. The decision as to which of these alternatives should be adopted depends upon the exact design of protection. Two of the rails which are shown in Fig. 3 are for under-contact shoes and one for top-contact shoes. Whilst Mr. Merz was in Melbourne some samples of typical forms of protection were made and erected on the track, and it was decided to leave these exposed to the atmosphere for a considerable time before coming to a final decision as to the best form of protection and kind of wood to adopt. He also had samples of various woods which it would be possible to use for this protection sent to England and tested in his laboratory, and, although it seems certain that Messmate gives the best result electrically, he withholds his decision as to the exact design of protection for the time being until it is seen how the samples erected in Melbourne stand the effect of sun and weather, and also until some further laboratory tests now being made are completed. The estimates, however, allow for the adoption of any of the type shown, and the specifications provide for the supply of rails, insulators, and bonds of such design that the conductor rail may be completely protected throughout its length.

On double-track roads the conductor rails for both tracks will be laid in the six-foot way, as shown in Fig. 4, thus leaving the tracks themselves, and the outside of the tracks, free from obstruction. Where there are level road crossings or special track work, such as cross-over roads or junctions, the conductor rail will be discontinued and the gap bridged by lengths of low-tension cable laid underground.

The rail bonds are to be placed under the existing fish plates. Section switches are to be installed in the signal-boxes at all junctions. The capital cost of the track equipment for the whole scheme is estimated at £568,139.

It is recommended that the trains be made up of standard train units consisting of one motor coach and one trailer coach, with a seating capacity of 160, and equipped with two motors on one bogie of the motor coach. The type of body recommended is a combination of the compartment and corridor coach, having cross compartments with separate sliding doors and communication on one side. The use of automatic doors is not recommended. Some of the existing trucks can be used

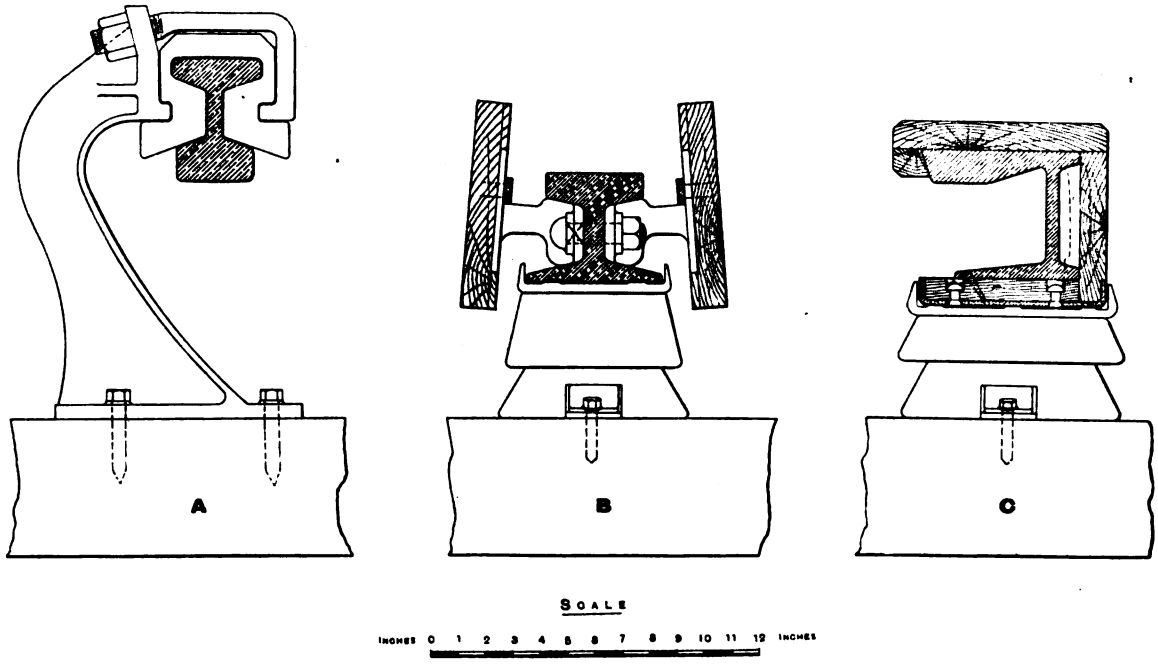

FIG. 3.—ALTERNATIVE TYPES OF PROTECTED CONDUCTOR RAIL.

FIG. 4.—SECTION OF TRACK SHOWING PROPOSED POSITION OF CONDUCTOR RAIL.

Digitized by Google

for trailers, but new motor trucks would, of course, have to be constructed. A certain amount of existing stock can be altered to become available.

Mr. Merz assumes that all the work in connection with the rolling stock for the electric service would be carried out in the railway workshops; he has, however, fully allowed in the estimates for the cost of this work, basing his figures upon the information prepared by the Chief Mechanical Engineer.

The report then deals with various auxiliary works, such as new block sections, systems of signalling and train despatch, alteration of existing lines, increase in the number of passenger stations, provision for holiday and race traffic, and general power and lighting, but makes no definite recommendation except that it would be better to defer making any radical changes in signalling and train despatching until experience has been gained from electric working.

Details are also given in the report of a general power and lighting scheme in connection with the railways.

With regard to the lighting of the stations, Mr. Merz recommends that all the stations in the central area be lighted by enclosed arc lamps or else by groups of metallic filament lamps. For stations outside the central area, he recommends that the lighting should be done from the conductor rail by means of incandescent lamps arranged in series. In the more important stations, where, on account of the number of offices and buildings, it might not be convenient to adopt series incandescent lighting, he recommends the provision of a small motor generator supplied from the conductor rail, suitable for transforming down to 100 volts and running in parallel with a small emergency battery. The average cost of wiring, fittings, &c., may be taken as ranging from £2 10s. to £3 per point for platform and outdoor lighting generally, and £1 per lamp for interior work. Arc lighting, with enclosed arcs, for piers and yards may be taken as £17 per lamp inclusive.

The following tables, taken from the report, summarise the capital and operating expenses, and compare the increased cost of electric service with the increased revenue derived :—

Table I.

Summary of Capital Expenditure involved by Electric Traction and Resultant Increased Interest Charges.

	Port Melbourne and St. Kilda Branches.	Stage I.	Stage II.	Stage III.
	£	£	£	£
1. Power Station, high-tension feeders and sub-stations, including spares for Power Department.	221,333	386,357	580,430	846,689
2. Track Equipment, including low-tension cables and alterations to permanent way, and spares	53,330	170,328	311,035	568,139
3. New Rolling Stock (less credits), alterations to existing stock and electrical equipments, including spares	67,674	221,657	426,044	754,881
4. Inspection Pits and Flinders Street Car Shed	14,392	23,538	45,179	57,341

Table III.

Comparison of Increased Cost of Electric Service with Increased Revenue due to Improved Facilities.

	Port Melbourne and St. Kilda Branches.	Stage I.	Stage II.	Stage III.
	£	£	£	£
1. Interest charges at 4 per cent. on capital cost of Electrification Scheme	12,600	26,077	43,520	72,058
2. Saving in operating expenses with Electric Traction ...	4,537	12,306	19,735	27,267
3. Extra cost of Electric Traction including interest charges	8,063	13,771	23,785	44,791
4. Additional increase in Revenue on a basis of 5 per cent. greater traffic, with Electric Traction...	2,500	11,073	20,520	28,632
5. Additional increase in Revenue on a basis of 10 per cent. greater traffic[1]	5,000	22,145	41,040	57,265
6. Additional increase in Revenue on a basis of 15 per cent. greater traffic[1]	7,500	33,218	61,560	85,897
7. Actual percentage increase of Revenue above the assumed normal growth of 20 per cent. necessary for the revenue at the different stages to balance the additional capital charges less the saving in operating expenses ...	16·1%	6·2%	5·8%	7.8%

[1] The estimates assume a difference of 5 per cent. only in additional revenue, but for convenience corresponding figures are also given for increases of 10 per cent. and 15 per cent.

The report concludes with the summary of conclusions given on p. 422 of our last issue.

Wireless Telegraphy in the West Indies and the Pacific.—An American Consular report gives some further particulars in regard to the network of wireless telegraphy which it is proposed to establish among the scattered islands of the Pacific Ocean, referred to in our last issue. It is stated that capitalists who are interested in the extensive phosphate operations on Ocean and Pleasant islands of the Gilbert group, and in the new works about to be established on the island of Makatea of the Tuamotu Archipelago, have recently begun a movement to connect nearly all the groups of islands in the South Pacific by a system of wireless telegraphy. It is proposed to include in this system the Commonwealth of Australia, the Dominion of New Zealand, the Fijis, the New Hebrides, the Solomon, Samoan, Cook, Society, and Marquesa islands, and the phosphate islands of Ocean, Pleasant, and Makatea. It is expected that the various governments having possessions in the South Pacific will aid in the establishment of the proposed system. Negotiations have already proceeded so far that the success of the efforts seems to be almost assured. As the nearest available ocean cable office to Tahiti is at Auckland, 2,250 miles away, from which a steamship of the Union Line of New Zealand arrives at Papeete once every 28 days, and a direct communication by a steamship of the Oceanic Co. with San Francisco, 3,658 miles distant, is had once in every 36 days, it will be understood how deeply interested the French colony of Tahiti and its dependencies are in the complete success of these negotiations. Other groups of islands are equally interested in the establishment of this system, which means so much to the inhabitants of these widely separated archipelagoes. The name of the proposed company is the Pacific Islands Radio-Telegraph Co. Of the proposed capital of £70,000, the owners of the phosphate deposits on Ocean and Pleasant islands have subscribed £10,000. In this radial system there will probably be ten or twelve circles, the largest having a radius of 1,250 miles, and requiring for each station an engine of 60 h.p. It has not yet been decided where the main office of the proposed company will be.

TWO NEW LIMIT SWITCHES

IN certain cases of electricity supply, the supply company has made arrangements whereby the consumer pays for current either on a contract basis or on a somewhat reduced flat rate, on the condition that the consumer's demand shall never exceed a certain amount. It will be remembered that a general tariff based on the same principle was recommended in a Paper read by Messrs. Handcock and Dykes before the Institution of Electrical Engineers last session. In such cases it is to the interests of the supplying authorities to see that the customer's demand never exceeds the predetermined amount, and for this purpose so-called "limit switches" are used. Two patterns which have recently been put on the market in Germany, are described in a recent issue of the *Elektrotechnische Zeitschrift*.

The first of these has been brought out by the Allgemeine Elektricitäts Gesellschaft, and is constructed so that, as soon as

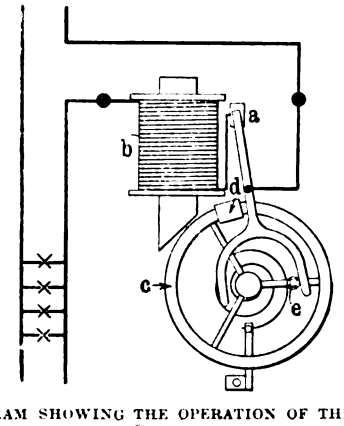

FIG. 1.—DIAGRAM SHOWING THE OPERATION OF THE A.E.G. LIMIT SWITCH.

the current exceeds the maximum permitted, the consumer's lamps are caused to flicker continuously, and thus warn him that he is taking too much current. The working of this switch can be understood by an inspection of the diagram in Fig. 1. In this diagram *a* is a switch in the main circuit, and *b* is an electromagnet which actuates the balance wheel *c*. The switch is in series with the magnet-winding, and the consumer's lamps. If the current exceeds a predetermined amount, the armature *d* is attracted to the electromagnet, and the balance wheel is set in motion. At a certain angle, the stud *e* on the balance wheel comes in contact with the forked end of the switch, and opens the circuit, putting out the lights. The magnet no longer attracts the armature, so the balance wheel swings back, and the circuit is closed again. So long as the load is not reduced this action is repeated; but, directly the current is reduced below the maximum permitted, the swinging ceases, and the switch is permanently closed. The apparatus is enclosed in

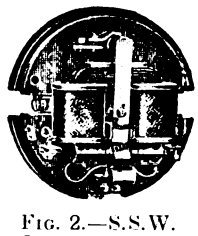

FIG. 2.—S.S.W. LIMIT SWITCH.

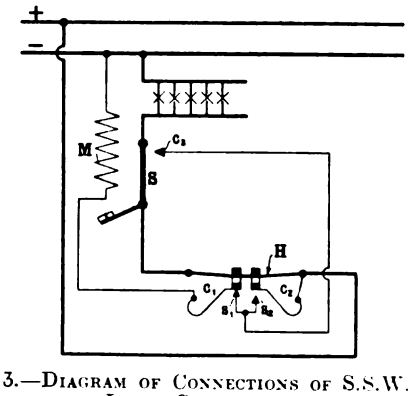

FIG. 3.—DIAGRAM OF CONNECTIONS OF S.S.W. LIMIT SWITCH.

a circular aluminium case, which measures 4¾ ins. in diameter, and is about 2½ ins. high. The standard sizes are: 5 amp., 150 volt, and 3-amp. 250 volt for continuous-current circuits; and 5 amp. 250 volt for alternating-current circuits: but of course they can be set to operate at lower current values.

The second pattern described is that brought out by Siemens-Schuckertwerke, of Berlin, and is illustrated in Fig. 2. The operation of this limit switch is shown in the diagram of Fig. 3. In this case, also, when the consumer takes too much current, his supply is cut off for a certain length of time. In the diagram, *S* is the switch in the main circuit, which is opened when the armature shown in the diagram is attracted by the electromagnet *M*. *H* is a stretched wire in series with the main circuit; c_1 and c_2 are contact springs, which tend to make contact with the corresponding contact studs s_1 and s_2, but are prevented from doing this as they are fixed to, but insulated from, the stretched wire *H*. There is a third contact stud c_3. The heating effect of the current causes the stretched wire *H* to lengthen, and first to make contact between c_1 and s_1; this, however, has no effect on the switch. Further heating, however, causes contact to take place between c_2 and s_2, which closes the shunt circuit from the positive main through c_2, s_2, s_1, c_1, and *M*, to the negative main. The electromagnet is energised and the circuit broken, but a new circuit through c_3, s_1, c_1, and *M* is made. The wire cools and the contact c_2, s_2 is broken; the electromagnet remains in circuit, however. After further cooling the contact c_1, s_1 is broken, the armature is released, and the main circuit closed again. This action is repeated continuously if the load is not reduced. The apparatus can be set to operate within 5 per cent. on either side of the permissible maximum current value, and is supplied for both continuous and alternating-current circuits up to pressures of 220 volts.

Wiring Rules.—The International Electrical Congress, which closed its sittings at Marseilles on Saturday last, adopted, among other resolutions, one suggesting that the International Electro-Technical Commission, which will meet in London, should consider the question of drawing up general regulations regarding electrical installations in the interiors of buildings.

Russia's Copper Output.—A British Consular report upon trade in St. Petersburg during 1907 gives some figures with regard to the output of copper in Russia during the year. According to preliminary figures published, the total quantity smelted in the country was about 14,401 tons, which is stated to be a record compared with previous years. To the above quantity of 14,401 tons, some 4,500 tons must be added, representing the import of electrolytic copper. At the present time Russia's capacity for producing electrolytic copper is far short of satisfying the demand. For the moment there is only one electrolytic plant in the country capable of producing a large quantity, though it is interesting to note that in the near future a British-controlled plant will begin operations in the Urals at Kyshtim. Last year Russia's consumption of electrolytic copper was about 5,700 tons, of which native works produced 1,200 tons, while, as stated above, 4,500 tons were imported. The total quantity of ordinary ingot (non-electrolytic) copper consumed in the country was about 13,000 tons, and about 1,400 tons were exported, this latter figure representing the surplus in excess of home requirements of ordinary ingot copper. There is a heavy duty on copper imported into Russia, approximating £33 per ton, but in spite of this fact the trade is by no means in a healthy condition, the main reason being apparently the excessive cost of output. There are at the present time three British copper-producing companies working in the Russian Empire, one in Siberia (Spasski), one in the Urals (Kyshtim), and one in the Caucasus (Caucasus Copper).

Electric Railway Accidents in 1907.—The general report of the Board of Trade upon accidents that have occurred upon the railways of the United Kingdom during the year 1907, states that with reference to accidents by contact with the live rails of electric railways, although these are not, as a rule, attributable to railway working, they are nevertheless distinctly railway accidents, although not caused by the movement of vehicles. To this cause is set down the death of one servant and injury to 13 in 1907. Precautions against recurrence of such accidents have been taken by covering the live rails at exposed places, improving fencing and posting warnings, and accidents of this class have become less frequent than they were when electrical working was first introduced, and the special danger which it involves was unknown. In addition to servants of the company three persons have been killed and four injured during 1907 through trespassing on electrically-equipped track, making the total accidents for the year four killed and 17 injured. The details of these are as follows:—Charing Cross, Euston & Hampstead Railway, one servant injured; Great Northern & City Railway, one servant injured; Lancashire & Yorkshire Railway, three servants and one trespasser; London & South Western Railway, one servant injured; Mersey Railway, one servant injured; Metropolitan Railway, two servants injured; Metropolitan & Great Central Joint Railway, one servant killed; Metropolitan & Great Western Joint Railway, one servant injured; Metropolitan & Metropolitan District Joint Railway, one servant injured; Metropolitan District Railway, one servant injured; North-Eastern Railway, one servant injured, three trespassers killed, and three trespassers injured. In 1906, four persons were killed and 21 injured in this way, in 1905, two were killed and 18 injured, and in 1904, when only three of the above railways were using electric traction, eight persons were killed and 20 injured.

ANNUAL CONFERENCE OF THE MUNICIPAL TRAMWAYS ASSOCIATION

THE seventh annual conference of the Municipal Tramways Association opened yesterday under the presidency of Mr. J. Aldworth (General Manager, Nottingham Corporation Tramways). A reception was held in the morning by the Mayor (Councillor Spalding), the Sheriff, and Chairman, and members of the Tramways Committee, at the Exchange Hall, after which the proceedings of the conference opened with Mr. Aldworth's address, which is given in abbreviated form below:—

Presidential Address.

After congratulating the members on another year's successful working of the Association, Mr. Aldworth suggested that the time had now arrived when the status of the Association should be raised, and that the Executive Committee be instructed to take the necessary steps to secure its incorporation. He mentioned that the membership of the Association now included over one hundred and twenty chairmen and vice-chairmen of committees representing practically all the local authorities operating their own tramways, with about one hundred general managers and chief officials, and remarked that local authorities had invested in these undertakings, roughly, 40 million pounds. They operated 2,500 miles of track with 8,000 cars and 40,000 employees, which served a population of 17¾ millions. Their joint revenue last year amounted to 8¾ million pounds, the number of passengers carried was 1,886 millions, and the cars ran 195 million miles.

The meeting of the Managers' Section was held this year at Wolverhampton, where opportunity was given to study the surface contact tramway system in operation there, and Papers were read on "Car Building in Departmental Workshops," and "Tramway Rating Valuations and Income Tax Assessments." Tabulated information respecting the distance at which a "Tramway Passenger paying a Penny Fare ceases to be remunerative," was also laid before the meeting.

Mr. Aldworth continued:—Although there has been no burning question before the members during the year, many matters of great importance to the tramway industry have been under consideration. Unquestionably the most important is that of brakes and safety appliances for cars. This has been emphasised by the distressing accidents which have taken place during the year. It is greatly to be regretted that such accidents should have occurred in spite of all the care and attention given to secure the safe working of the undertakings, and the splendid records that had been established as regards immunity from serious disasters. A large number of meetings of the Brakes Committee of the Association have been held, many undertakings visited, and a considerable number of brakes of various designs inspected and tested in operation. Exhaustive experiments and tests have also been carried out, and it is hoped that the results will indicate means by which the risk of accidents arising through cars getting out of control may be greatly minimised, if not entirely removed. The important question of what allowance should be made for depreciation of assets by the Board of Inland Revenue, when dealing with the profits for income tax purposes, has been receiving very careful attention, and appreciable progress has been made towards arriving at a settlement of this very complex subject.

Other matters, including proposed new regulations by the Board of Trade; the use of tramway poles for telegraph and telephone purposes; corrugation of rails; the maintenance of street paving along tramway routes; the report of the Departmental Committee on Accounts of Local Authorities, and Mutual Assurance against Third Party Risks, have also been under consideration by the Executive Committee. It is very disappointing that no solution of the rail corrugation problem is forthcoming. This is becoming a serious matter with many undertakings.

In speaking of the relations between the officers and staff, Mr. Aldworth said:—It is to be regretted that efforts have been made, in a few cases successfully, to transfer the decisions on matters of discipline from the manager to the committee, in other words, from an impartial to an interested tribunal—a departure from the policy which, it is generally conceded, has in the past worked very satisfactorily. The result of this means practically the transference of responsibility for the safe and efficient working of the undertaking from the manager to the committee: a serious departure indeed, as responsibility without control is impossible in any real sense. It may relieve the manager of a very onerous responsibility, but committees as well as the public who use the tramways might seriously consider whether such a procedure is not calculated to jeopardise the efficiency and safety of the service.

It is essential that the public should be given the best possible service, and carried at the lowest fares justified by the returns, but not lower than will permit of the undertaking being conducted on sound commercial principles. This result cannot, of course, be general so long as there are undertakings which run only through thinly populated districts attempting to compete in the matter of fares with other systems serving large cities with a dense population. In most of such districts the cost of living is considerably lower than in large towns, and in those districts the public can afford to be satisfied with being carried a shorter distance than is given for the same fare in large centres. This important fact should be taken into account by committees when determining their fares and stages. A satisfactory sign of the times is that much less is now being heard of the demand for halfpenny fares and stages, and many other concessions of a hazardous nature, which at one time were being so vigorously pushed, irrespective of local conditions.

On the question of intercommunication evidently a much broader view is being taken, as is shown by the continual increase in the number of municipalities which have entered into working agreements for this purpose with other undertakings, both municipal and company-owned. There can be no question that such arrangements give facilities which greatly encourage the use of the cars, and increase the usefulness and earning capacity of the undertakings concerned.

A matter providing a large field for thought, and deserving of our serious consideration, is the adoption of an improved method of collecting and checking fares. A considerable amount of attention has been given to this problem for some time past, and the "Pay as you enter Car" which is being introduced into Canada and the United States, appears to be making progress in this direction. Where a universal flat fare is in operation, this system appears to be an excellent one, and it now remains for some inventive genius to devise an equally effective method applicable to the general conditions prevailing in this country.

We are all more or less familiar with the irritating sound of cars running over defective rail joints and worn points and crossings, and we appreciate the great damage to the rolling-stock and rail bonding, as well as the discomfort caused to passengers and residents along the route. Recent improvements will, undoubtedly, go a long way to obviate this with new tracks; but the difficulty is to overcome the trouble on lines which have been in use for some years. A number of methods have been tried to this end with more or less success. In Nottingham the matter has received very careful attention, and as a result of experiments, extending over several years, it has been decided to repair defective joints by cutting away the worn portion of the tread and inserting a flat plate of special steel, which bridges the rail joint and rests on both rails. The ends are splayed and dovetailed into the rails. During the three years since the first joint was so treated not a single plate has worked loose, notwithstanding that there has been a two-and-a-half minutes' service running over the route. In this country, as in America, the method of conducting energy from the overhead wire to the car equipment is by means of the "grooved trolley wheel." The disadvantages of this system are all too well known, and many devices have been designed and tried for overcoming them. In many large cities on the Continent the "bow trolley" is almost universally employed. There is here ample scope for investigation of the comparative advantages and disadvantages of the two systems.

Very little, excepting complaints, is now being heard of the petrol motor 'bus, which a few years ago we were told was going to revolutionise street passenger traffic and practically exterminate tramways. The petrol motor 'bus has had a fair and impartial trial, and the verdict is certainly not in its favour. The electro-'bus now being tried is certainly free from many objectionable features inseparable from the petrol vehicle, and is far cleaner and more comfortable in every respect; but whether accumulators can be found to withstand the vibration and strain to which they are subjected, especially on rough and hilly roads, and enable the 'bus to be worked at such a cost as will allow it to give a fair return on the outlay, remains to be seen. So far, no reliable figures in connection therewith are forthcoming, and there appears to be as much uncertainty on this point as there was originally about the petrol 'bus.

Digitized by Google

There is unquestionably a large field available for the successful working of a service of self-contained, reliable, and economically-operated vehicles. There are very few towns that have not some districts which could be connected with the tramway system by such means. Not only would they be greatly benefited by the adoption of these vehicles, but the traffic thus created would add considerably to the tramway receipts. The merits of the "Trackless Trolley Car" are now receiving careful attention, and it is satisfactory to know that one of our municipalities intends giving the system a trial. It will be watched with very great interest, and I trust that ere long we shall be in possession of reliable information as to the results of its working under British conditions. If these vehicles can be made to pay their way and at the same time gradually create such a traffic over the routes on which they are used as will justify the laying down of tramways, their introduction will prove a valuable factor in the extension and linking up of tramway systems.

After the presidential address the following Paper was read:—

Some Through-Running Problems and their Solution.

BY H. E. BLAIN (*Tramways Manager, County Borough of West Ham*).

The aim of this Paper was not to deal with all the through-running arrangements which have been tried, but rather to classify the main principles upon which experience shows that through running can be arranged to the mutual advantage of the contracting parties, and to the convenience of the travelling public. After quoting figures published some years ago by Mr. Stephen Sellon demonstrating the advantage to both systems working under a through-running arrangement, notably at Newcastle and Birmingham, the author thinks it hardly necessary to say anything to commend the "making" of through-running arrangements to every manager whose system adjoins any other system, whether Corporation or company, but "there are unfortunately tramway undertakings still with us which apparently desire to become firmly established as the High Priests of Haughty Isolation, with a Hindoo-like dread of any other tramway undertaking even casting the shadow of a trolley-pole over a corner of the sacred area within which any of their car mile meals are taken." This policy is regarded as financially unsound, a view which, the author says, is supported by an examination of the accounts of such undertakings. In fact, the whole-hearted view is taken, in sharp contrast to the opinions which existed almost universally amongst municipal tramway managers only a few years ago, that there are now so many through-running arrangements which have stood the test of time that there does not seem to be any valid excuse for change of vehicles being necessary where physical contiguity obtains, and in the London area, for example, it is certain that one of the strongest reasons for the establishment of a Central Traffic Board is the continued unwillingness on the part of some of the tramway-owning authorities to provide proper through-running facilities for the convenience of the public; a short-sighted policy to which much of the present motor-bus competition is due.

Through-running agreements divide themselves into four classes as follows:—(*a*) In which foreign lines are leased and operated by another authority. (*b*) In which both contracting parties run cars and each through passenger receives two tickets, either by a change of conductors at the boundary, or by each of the authorities furnishing the other with tickets to be sold when the boundary has been crossed. (*c*) In which both authorities run the number of cars to which their local mileage on the through route entitles them, the respective areas being taken as of equal earning value, and each authority retains all the receipts taken on its own cars. (*d*) In which both authorities run cars and the receipts are apportioned upon an agreed basis. The first, of course, is the simplest method, and is adopted in a large number of places, the details of the agreement varying according to local circumstances. Particulars are given of some 33 through-running agreements, including Birmingham, Blackburn, Burton-on-Trent, Bury, Manchester, Liverpool, Dundee, Kirkcaldy, Leeds, Sheffield, West Ham, and Wolverhampton, all arranged under one or other of the above classes, in many cases between local authorities and companies. The author hopes to show such tramway-owning authorities and tramway managers as are still unrepentant and unashamed obstructors of through-running facilities that such facilities are easy of arrangement, fair and remunerative to all parties concerned, of the greatest value in stimulating and increasing traffic, and are a public and private convenience which no authority which claims to be the representative of the public and the guardian of the public weal has a right to hinder.

In the afternoon the Trent Bridge Car Repairing Works and the St. Ann's Well Road Generating Station were visited. Both of these were described, in connection with the annual convention of the Incorporated Municipal Electrical Association in June, in ELECTRICAL ENGINEERING, Vol. III., pp. 965 and 971. A reception was held in the evening at the Art Museum, Nottingham Castle by the Mayor and Chairman and Vice-Chairman of the Nottingham Tramways Committee.

CORRESPONDENCE

SYMBOLS FOR PHYSICAL QUANTITIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Now that there has been some opportunity for discussing this question, may I be permitted to summarise the arguments that have been raised for and against the creation of new symbols? The most common objection is, "They are like Chinese characters; we could never remember them." But there will be no necessity to remember them. How many of us can remember what symbol Rankine uses for kinetic energy? Is it not sufficient for us to see it when we refer to his book? Every considerate writer to-day gives a list of the symbols he uses. If all writers used the same symbols we should soon become familiar with those with which we are most concerned, and for the rest, we would refer to the list just as at present.

Some objectors do not see why the letters we have at present are not sufficient. Let them try to make a list of symbols for the 200 physical quantities for which symbols are wanted. After they have made up a list to satisfy themselves (if such a thing is possible), let them try to convince someone else to adopt that list. There are about 20 letters, such as *m* for "mass," *t* for "time," &c., upon which there is almost universal agreement. One or two dozen more stand a fair chance of being agreed upon. Beyond these, there is hopeless confusion, simply because all the good letters are exhausted. As to the difficulty of printing new symbols, it is of interest to know that 25 of the leading technical journals of the world published an article containing five new symbols given as examples, without any difficulty. Several of them have expressed the view that there is no difficulty from the printer's point of view. The types supplied to them—which, by the way, cost 1d. for 30—were all of one size, and yet each paper used for the text of the article its usual standard type. The publisher of the *Elektrotechnische Zeitschrift* thinks that there would be no difficulty in arranging with a typefounder to make matrices, from which all printers could be supplied with type. Each printer would keep in stock those types which commonly occurred in his paper, and could get others on short notice. About 30 new symbols would be sufficient for articles on electro-technical science. Two papers have objected that the symbols cannot be set up on a linotype machine. It is, however, usual at the present time to set up mathematical expressions by hand.

Several critics have pointed out that the new symbols should be bold and simple in outline, so that they cannot be easily mistaken for one another. This, of course, is an important matter to bear in mind. I agree with M. Galliot that the name of the symbol should be, where possible, the name of the physical unit represented. Where the name of the unit cannot be employed, a word of one syllable might be chosen, as, for instance, "stroke," for the length of a piston stroke. Some critics say that the number of symbols required would be too great. As to that, we can make just as many as convenient. The symbol ~ became universal almost as soon as it was printed. Let us have a few more as good as that one; we are badly in need of them.

Yours faithfully,

MILES WALKER.

Hale, Cheshire.
Sept. 19th, 1908.

Deaths from Electric Shock.—Whilst a man was painting the girders of the overhead work carrying the conductors of the single-phase system of the Midland Railway Co. at Lancaster Castle station, on Friday, he received an electric shock which killed him before he could be rescued. It was stated that the man received a message that the current was to be switched on, and was endeavouring to get off the girder when he touched the overhead conductor.

An inquest was held last week into the death of a trammer, employed by the Wharncliffe Silkstone Colliery Co., at their Knoll Drift pit, Barnsley. The deceased man was engaged in moving some corves, *i.e.*, steel trucks, and was standing in water at the time, when he received a shock from a cable, brought down by a fall of roof, which had made contact with the corve.

THE FALCON SPINNING MILL

WE were recently given the opportunity of inspecting the Falcon Spinning Mill at Halliwell, near Bolton, which is an extremely interesting example of electric driving. This is a typical case where electricity can be used to the best advantage, as the mill in question is a new one, and it has therefore been possible to arrive at an even more effective and economical arrangement than can be the case where electric motors are installed in an old mill to displace the previous rope-drive.

The mill is what is called a "superfine" mill, for spinning superfine yarn from No. 100s. to No. 300s. For this work a close speed regulation is essential, much more so than in the case of coarser yarn. Bolton, it may be mentioned, is the centre of this extra fine spinning industry, and the result obtained from this mill will therefore be watched with considerable interest. At the time of our visit the mill was not yet in operation; when the cotton industry resumes its normal condition there is no doubt that this will be one of the most active mills in the district, as there are 100,000 mule spindles. Another interesting point in connection with the mill is that it has its own power-house, in which the first Zoelly turbine built entirely in England by Messrs. J. Musgrave & Sons, Ltd., who are one of the three licensees in this country under the Zoelly patent, has been erected.

Fig. 1 is a reproduction of the pipe plan, which indicates the general lay-out of the generating plant. There are three 30 ft. × 8 ft. Yates & Thom Lancashire boilers for 160 lb. pressure, fitted with Sugden superheaters in the down-take, designed for a superheat of 150° Fahr. Each superheater contains 220 sq. ft. of heating surface. In the Sugden superheater, instead of the tubes being placed in contact in long rows, they are disposed in groups with a large space between each group. The object of this is to prevent undue punishment to the front rows of tubes, and the work is thus more evenly divided between them and the back rows, tending to ensure greater efficiency and longer life. To protect the superheater when steam is first being raised, and also from the effect of protracted stoppages, a system of isolation and damping is employed in place of flooding. The arrangement is shown in Figs. 2 and 3. In Fig. 2 the dampers are closed, and the whole of the heated gases impinge against the superheater tubes. In Fig. 3 the superheater is entirely isolated by the dampers in their upper position. The steam piping is so designed that the superheater can be isolated, and saturated steam passed directly to the turbines.

Green's economisers are used; there are 288 vertical heating tubes, roughly speaking nearly 3,000 sq. ft. of heating surface. The economiser is arranged on the modern principle in three groups of 96 pipes each; expansion elbows top and bottom couple these groups together, and thus easy access to any part of the apparatus is possible.

In the engine-room, when complete, there will be two Zoelly turbines, each driving three-phase alternators, by Siemens Bros. Dynamo Works, Ltd., having a normal output of 400 kw. The sets are designed, however, to supply, if required, 800 kw. for ten hours, or 600 kw. absolutely continuously. At the time of our inspection, only one of the sets had been installed, but we understand that the second one will be put in very shortly. By giving these large overload capacity, the necessity of duplicate or spare plant is obviated. This is an important consideration in cotton mills, for there are many cases in which mills have been driven by large horizontal Corliss

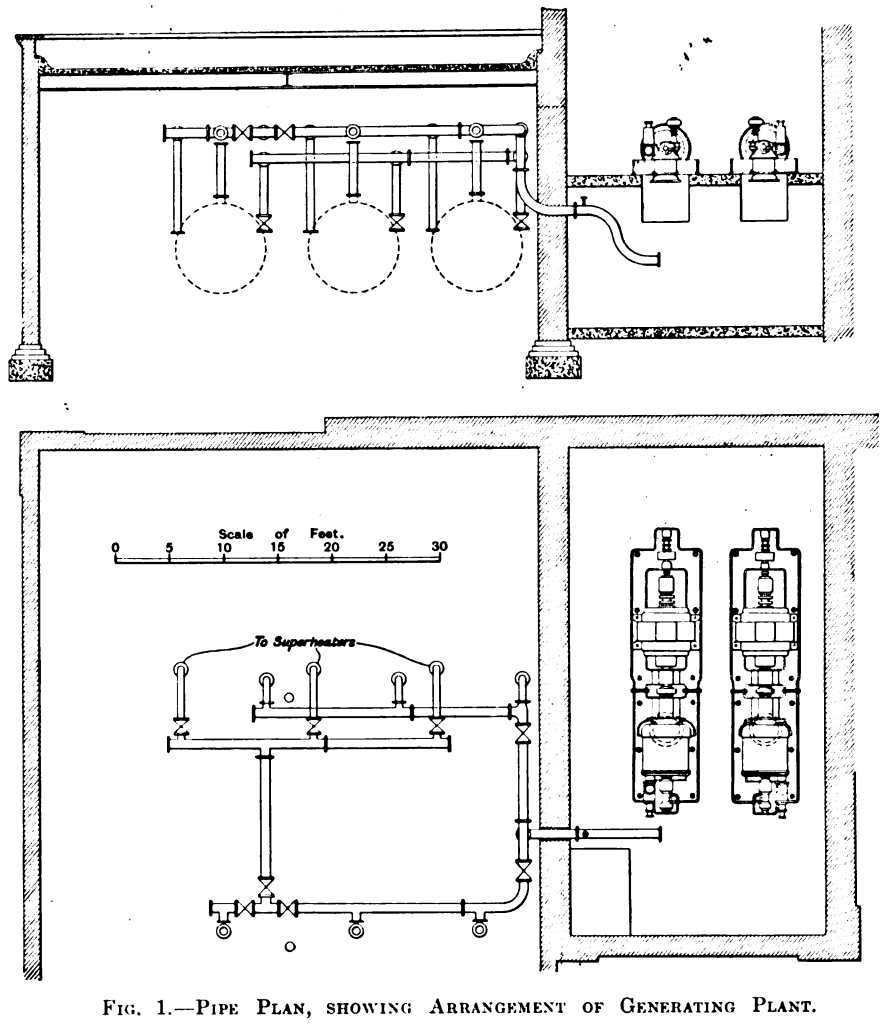

FIG. 1.—PIPE PLAN, SHOWING ARRANGEMENT OF GENERATING PLANT.

engines for years continuously without a single stoppage, and cotton spinners are therefore inclined to regard with suspicion any new machine which it is deemed necessary to duplicate in the event of breakdowns.

The Zoelly turbine is one which runs at a high speed, and the speed of these sets is 3,000 revolutions per minute. Each turbine is fitted with overload device which cuts off steam at 10 per cent. overload.

No actual tests have yet been made of steam consumption but it is confidently anticipated that the full load consumpion will not be higher than $11\frac{3}{4}$ lb. per b.h.p. at 28 in. vacuum. One of the special features of the Zoelly turbine, moreover, is the comparatively small steam consumption at lower loads. Fig. 4 gives a steam consumption test of a 2,000 kw. Zoelly turbine, from which the relative steam consumptions may be seen in the case of a large machine.

The section of the turbine is shown in Fig. 5, on

Digitized by Google

which is also a view to a larger scale of the wheel and nozzle plate showing clearly the method of fixing the blades of the running wheel. The Zoelly is a parallel-flow turbine with pressure stages, in which the steam is expanded by the fixed blades, and the velocity only

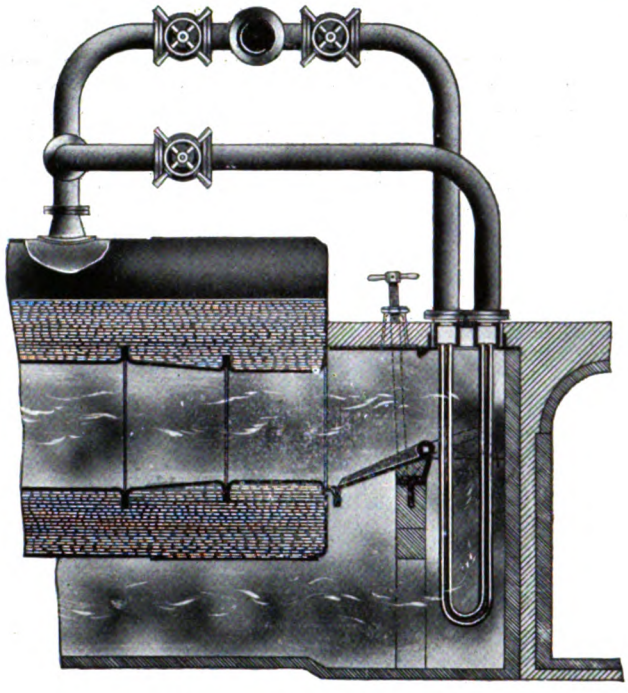

FIG. 2.—SUPERHEATER WORKING: DAMPERS OPEN.

is used on the moving blades, as distinguished from the reaction type, in which the expansion takes place in the moving blades. One of the features of this type is that the clearances can be larger than in turbines on the Parsons principle, and the danger of stripping is

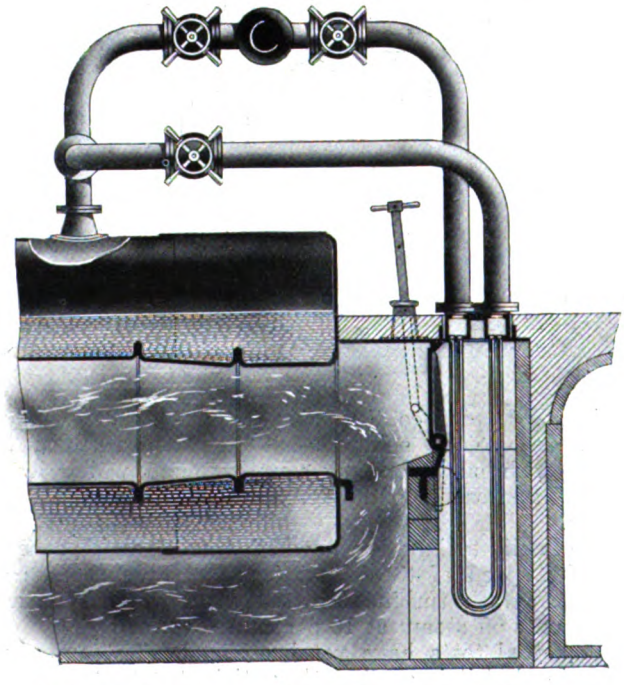

FIG. 3.—SUPERHEATER ISOLATED: DAMPERS CLOSED.

eliminated. In this particular set, the radial clearance is a full $\frac{1}{8}$ in., and in other directions even more. Steam enters the first high-pressure wheel chamber at the left-hand end in the section in Fig. 5, and passing through the nozzles is expanded down to a certain point. After doing its work on the running wheel, it passes through similar nozzles into the next chamber, and so on through each successive chamber to the exhaust port. In the turbine at the Falcon Mill there are ten expansions, and in the larger sizes the number is gradually increased, reaching 20 in the 6,000-kw. sizes. The fall of pressure in each stage is practically 58 per cent. of that in the previous one.

In following out the construction of the blades and guide wheels reference may be made to Figs. 6, 7, and 8, in addition to the section in Fig. 5. These three figures show a single blade, a section of the running wheel, and a section of the guide wheel respectively. The shape of the blades and the method of fixing is indicated in Figs. 6 and 5. Nickel steel is the material of which the blades are made, and they are thickened towards the base, so that the stress on the metal is the same at every radius. The disc in which the blades are fixed is of steel, and it is forged in one piece with the boss, and is annealed several times during machining. The blades are fixed into the disc by means of a riveted clamping ring, and the square dovetail joint seen in the illustrations prevents any outward thrust. The nozzles are of nickel steel sheet, cast into the frame of the guide wheels, which are of cast steel for the higher-pressure stages, and cast-iron for the lower pressure. As the pressure gets lower from stage to stage, a greater number of blades are, of course, necessary, and thus the diameter at the low-pressure end is greater than at the high-pressure end.

Heavy overloads are taken by bye-passing the high-pressure steam to the fourth wheel chamber.

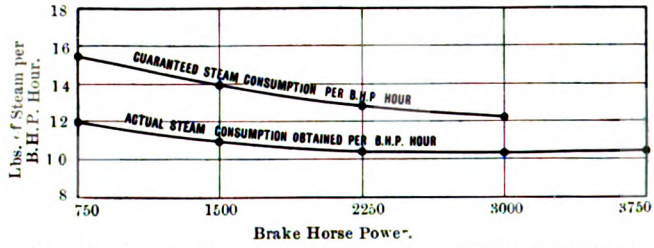

FIG. 4.—STEAM CONSUMPTION TEST OF A 2,000-KW. ZOELLY TURBINE.

An oil relay governor is employed. The governor lever controls a small distributing valve, which admits oil under pressure to the top or bottom of the cylinder seen in section at the top of the extreme left of Fig. 5. Two small oil pumps are driven off the governor spindle: one for supplying oil for this purpose, and the other for the bearings.

The turbines exhaust into a Klein barometric condenser. The drum of this is higher than usual, so that the water may gravitate on to a low cooling tower to save an additional pump. This cooler consists of 20 bays, each 10 ft. × 6 ft. The air pump is driven by a 10-b.h.p. 500-volt three-phase Siemens motor with a wound rotor, which is short-circuited when up to speed by means of a special switch at the end of the slip-rings, and at the same time the brushes are lifted. This set (which runs at 500 revolutions per minute) is placed in the engine-room.

Messrs. Siemens Bros. Dynamo Works, who have been responsible for the entire lay-out of the plant (at their Manchester branch), have supplied the alternators and all the motors, &c. The alternator is a two-pole three-phase machine, with a frequency of 50 cycles per second, and a voltage of 500. Its normal load is 460 k.v.a. at 0·87 power factor, and it is, of course, directly coupled to the turbine. A feature is the method of axial ventilation, which is now Messrs. Siemens' standard practice for such machines. A distributed field winding is employed on the rotor. The machine is totally enclosed, and the rotor bears a fan, inside the case, which draws the air up from an inlet pipe below, and passes it through the rotor and the stator windings.

Digitized by Google

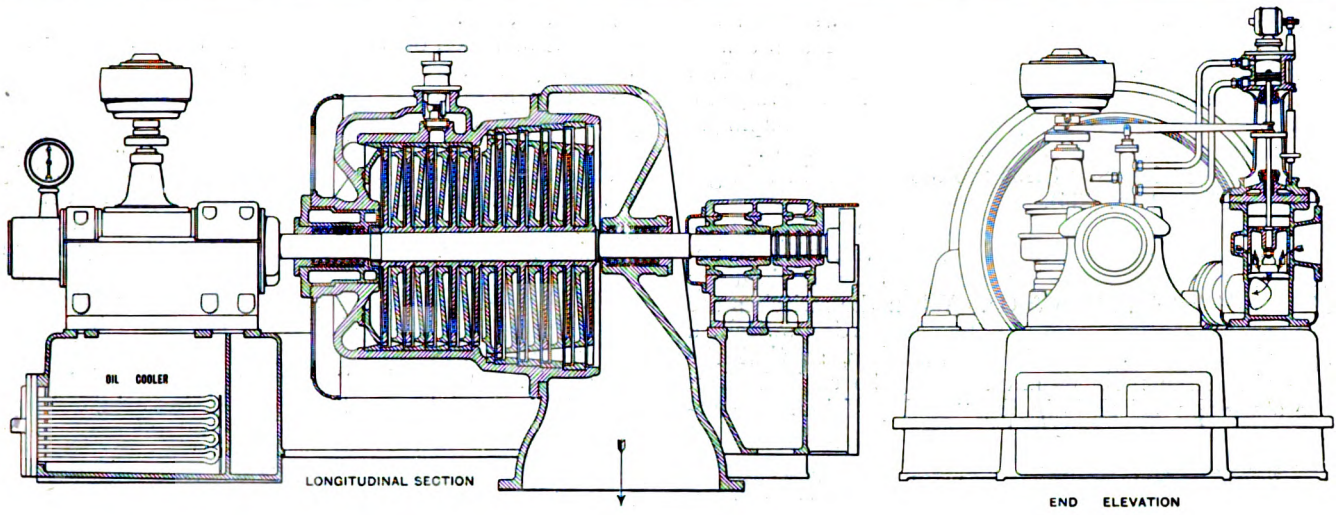

Fig. 5.—600-kw. Zoelly Steam Turbine.

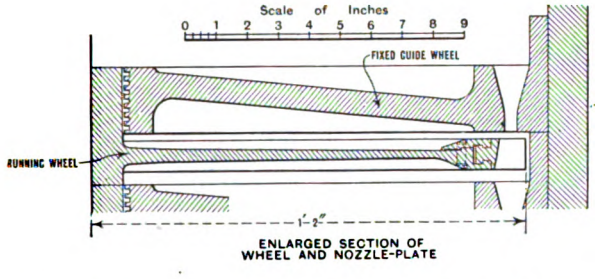

Contrary to the usual practice on rotors with distributed windings, the rotor is wound with strip on edge. All the stator windings on the machine have an open passage immediately behind them for the circulation of the air which escapes at the top of the machine by an outlet seen in Fig. 9. The calculated efficiencies of the alternator are as follows:—100 per cent. overload, 92·6 per cent.; 25 per cent. overload, 91 per cent.; normal load, 87·5 per cent.; three-quarters normal load, 84 per cent. The exciters are placed at the end of the main shaft, and are 60-volt compound-wound

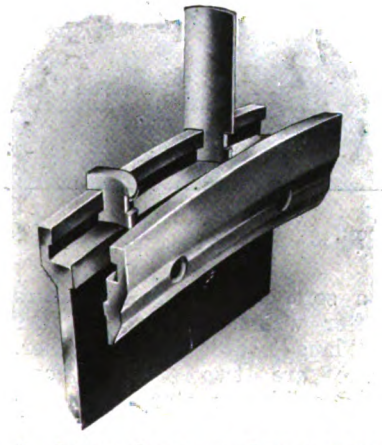

Fig. 6.—Single Blade of Zoelly Turbine.

machines with commutating poles. Voltage regulation is by means of resistances in series with the alternator field.

In addition to the main generating sets, there is a 34-kw. 105-volt Browett-Lindley-Siemens D.C. set used for lighting in the early morning before the main set is started up. Normally the lighting is supplied from the alternators through 500:105-volt transformers. Tantalum lamps are employed throughout for the lighting of the mill.

The switchboard calls for no special description. Knife switches are employed and plain copper fuses, which are passed through asbestos tubes. Each of the large main motors has its own distributing panel, and a throw-over switch is provided for connecting up the lighting circuits, either to the transformer or the small

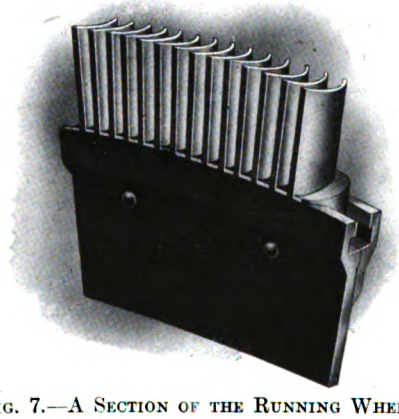

Fig. 7.—A Section of the Running Wheel.

generator. The mains from the generators to the switchboard are of bare copper tape on insulators, and three-core wire-armoured vulcanised bitumen cable is employed for circuits from the switchboard.

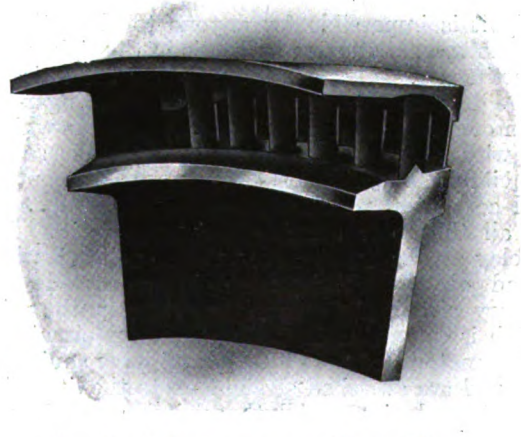

Fig. 8.—A Section of the Guide Wheel.

The arrangement of the main motors for driving the various floors of the mills is shown in Fig. 10 (p. 463). This is an adaptation of the usual rope-race arrangement

Digitized by Google

in an ordinary cotton mill, for the motor tower takes the place of the rope race. The dimensions of this tower, however, are less than that required for the rope drive. It is seen that there is a motor on each floor driving one or two long lines of shafting (through flexible couplings) to which the various machines are connected. The arrangement of one of these motors is seen in a larger scale in Fig. 12 (p. 464).

At the motor end of the circuit, each motor is controlled by an oil-break switch, with overload and no-voltage releases, according to a system devised by Messrs. Eckstein, Heap & Co. When the switches are used in connection with a star-delta starting switch, a special contact is fitted to the switches, so that the solenoid of the main circuit can only be excited when the star-delta switch is in the "off" position. Consequently it is impossible for anyone to close the main switch unless the starting switch is in the right position for starting up. Figs. 13 and 14 show the switch and tripping device separately. A similar arrangement is used in conjunction with the 200-h.p. motors which are fitted with slip-rings and starting resistances in the rotor circuit, only in this case the extra contact is placed so that the solenoid can only be fully excited when all the rotor starting resistance is in. A two-pole relay breaks the circuit of the no-volt coil when an overload occurs. This relay is connected to the secondary circuit of a current transformer, the primary of which is connected in the main motor circuit. The smallest motors (of from 3 to 7 h.p.) have squirrel-cage rotors, and are switched straight on to the line without any starting device. All the switches are in water-tight cast-iron cells.

We will not pretend to describe the process of cotton spinning, and the notes which follow must be regarded rather as an indication to the electrical engineer, in an exceedingly rough and approximate manner, of the nature of the various stages of manufacture, than an actual description of what goes on in a mill. They will serve to guide them, however, to some extent as to the names of some of the machines and the amount of power required for the work.

The first room is the mixing room, in which bale-breakers and mixers are placed. These are driven by a smaller motor and not by the tower motor. On the ground floor also is a 200-h.p. slip-ring induction motor running at 585 r.p.m., and directly coupled by means of a flexible coupling to the line shaft, from which six pairs of mules will be driven. This motor is of 200 h.p., simply to be a duplicate of those above it, and to allow for extra mules being added later. On the first floor (Fig. 11) are the "blowing-room" and "card-room." In the former the cotton is opened out and made into a sort of wad, and then rolled up into a "lap," after which the lap is further cleaned, and four "laps" are put together. For this process there are two "single openers," each belt-driven by a 5-h.p. motor, a larger single opener with a hopper and pneumatic conveyer, belt-driven by a 7-h.p. motor, and a fan requiring 3 h.p. The motors for all these are of the squirrel-cage type, running at 1,410 revolutions per minute. On this floor also is the "carding" room. Carding is the final cleaning process. The machinery is driven by a 50-h.p. motor, which is directly coupled to a line shaft through a flexible coupling, and running at 360 r.p.m. This motor drives forty 38-in. "cards." It stands on heavy iron brackets, supported from the mill wall, and is started up by means of a star-delta switch. There is also one 40-h.p. inverted motor with similar control, running at 365 r.p.m., directly connected to a line shaft through a flexible coupling, and driving four "ribbon" laps, four "sliver" laps, 26 cards, and 26 combers. A 90-h.p. motor placed in the motor tower, running at 365

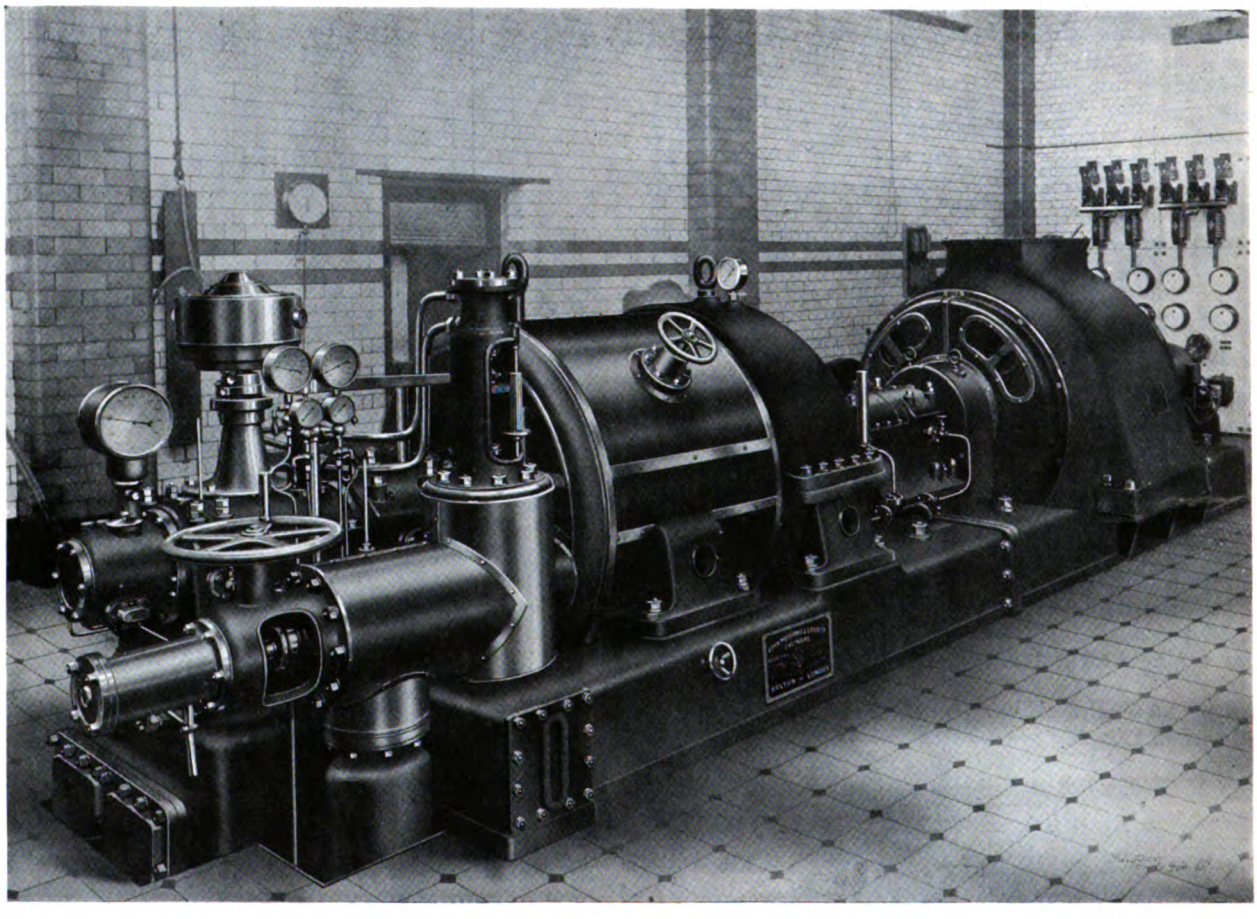

FIG. 9.—VIEW OF THE ENGINE ROOM.

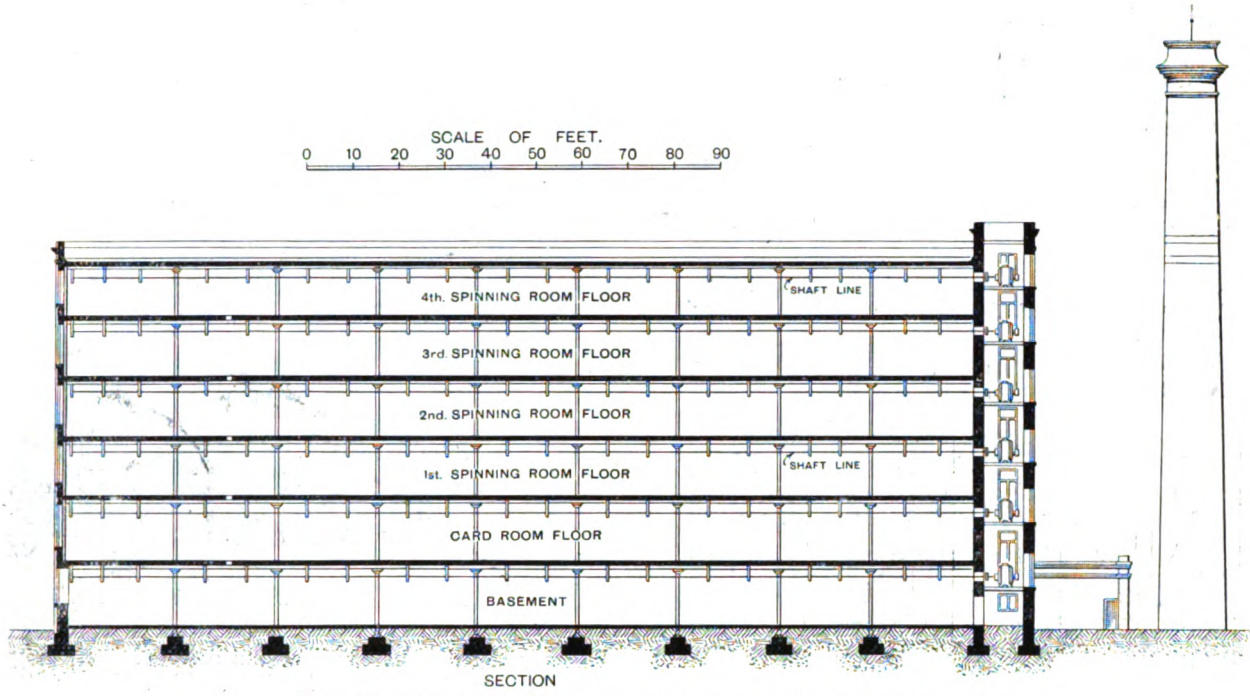

FIG. 10.—SECTION OF BUILDING SHOWING THE MOTOR TOWER.

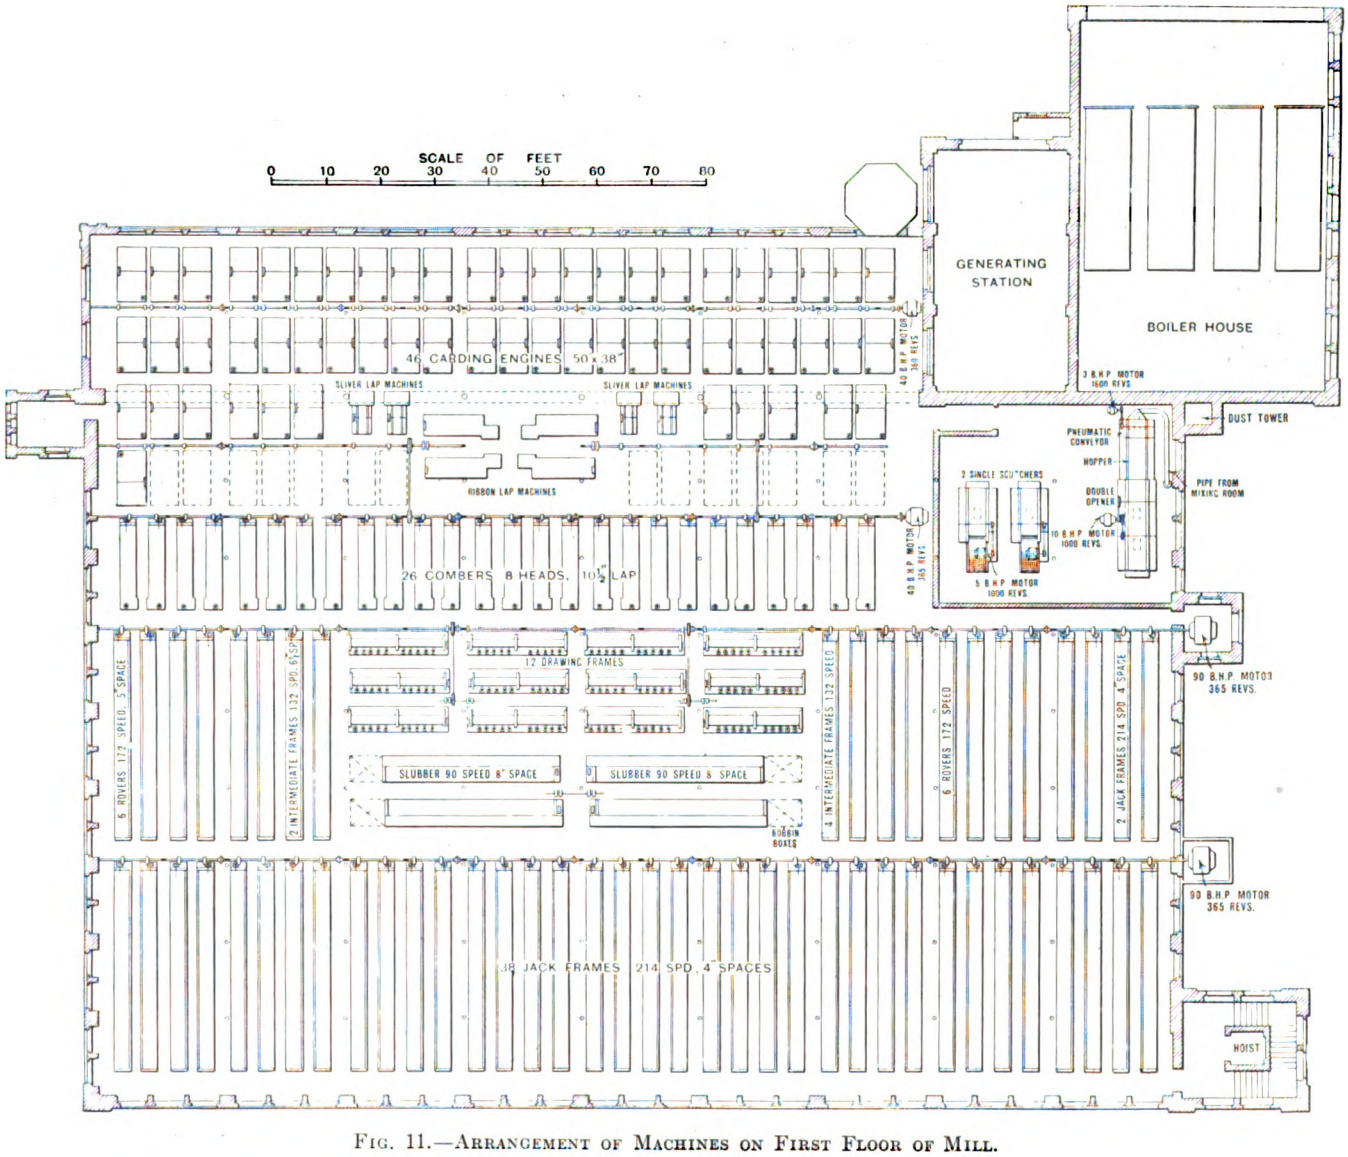

FIG. 11.—ARRANGEMENT OF MACHINES ON FIRST FLOOR OF MILL.

Digitized by Google

r.p.m., and with star-delta switch control, drives 12 "roving frames," six "intermediate frames," 24 "combers," four 38-in. cards, two "jack" frames, and 12 "drawing" frames. Another similar 90-h.p. motor drives 38 "jack" frames, and four "slubbing" frames. The brushing and blowing process is longer in the case of a "superfine" mill than in a coarse mill, and the number of machines is greater. The "sliver laps" put the material into "laps," the "combers" take out the short lengths, and the "slubbing frames" or "slubbers" finally wind it into spools. From this point onwards the process practically consists of winding pairs of threads together and drawing

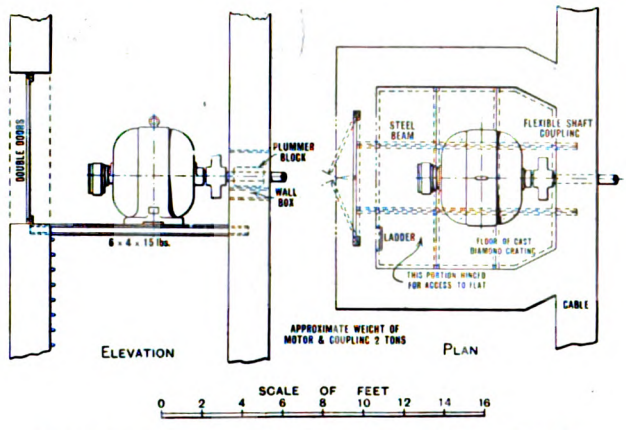

FIG. 12.—ONE OF THE MOTORS IN THE MOTOR TOWER.

out until the final fine thread is obtained of requisite strength and diameter.

On the second, third, and fourth floors are the "mule rooms," where the last stages in the process are carried out. The threads are wound off and stranded together. The spindles which wind off the thread from the spools are driven by thin cotton cords from tin rollers, which are in their turn driven through gearing in the centre of the room from the main shaft. This shaft is driven by the motor in the tower, as already explained, and the lines of mules are at right angles to this shaft. The motor on each floor is a 200-h.p. ventilated enclosed motor of the slip-ring type, running at 580 r.p.m., and the control is that already described

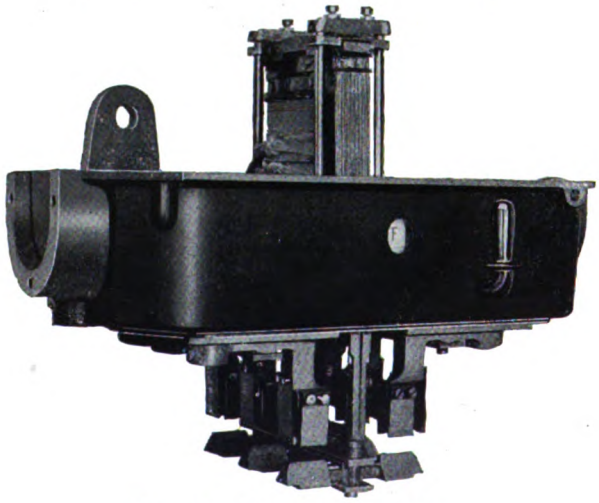

FIG. 13.—MOTOR SWITCH OPEN.

for slip-ring motors. These motors each drive 18 mules of 1,142 spindles each, 1¼ in. gauge. The spindle speed is between 7,000 and 8,000 r.p.m.

We are indebted to the Falcon Mill Co., Ltd., for permission to inspect the mill, and also to Messrs. John Musgrave & Sons, Ltd., and Messrs. Siemens Bros. Dynamo Works, Ltd., without whose ungrudging assistance the preparation of this article would have been impossible. For the very vague, and, we fear, unsatisfactory description of the spinning process itself, we alone are responsible, but our readers are naturally more

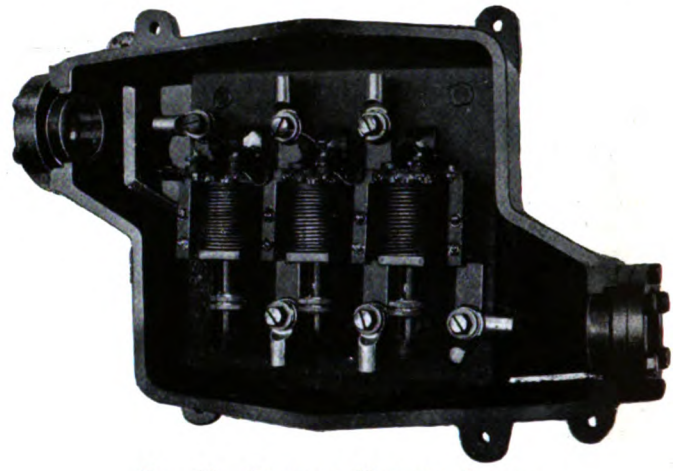

FIG. 14.—OVERLOAD TRIPPING DEVICE.

concerned with the applications of electric driving and the design of the new Zoelly turbine than with the precise methods employed in spinning cotton. Our thanks are also due to Messrs. George Temperly & Son, the architects, for lending us the drawing showing the section of the motor tower.

FIRE AT THE PARIS TELEPHONE EXCHANGE

A FIRE occurred at the main Paris Telephone Exchange between 8 and 9 o'clock on Sunday evening, which resulted in the whole of the centre of Paris, on the right bank of the river Seine, being cut off from telephonic communication. The fire was not overcome until nearly midnight. During the past few weeks the system in Paris has been undergoing conversion to the central battery system, and it was whilst the workmen had left the building for a short while that the fire was discovered in the basement. At the moment some 200 telephone operators were on the premises, but they were able to leave by the emergency doors without harm. As there is a fire-station only a very short distance away from the Telephone Exchange, some twenty engines were quickly at work, but just as it seemed that the fire on the first and second floors had been got under control, the third and fourth floors were suddenly seen to blaze, and eventually the whole of the building was completely destroyed.

It is estimated that material to the value of £800,000 has been burnt, in addition to the complete breakdown of the entire telephone service in Paris and between all provincial and foreign cities. No less than 19,000 subscribers are affected. The fire spread with extraordinary rapidity, and the frequent explosion of carboys of sulphuric acid made the work of the firemen particularly dangerous. According to the *Times* account the only part of the interior of the building which was not absolutely destroyed is a portion of the interurban switchboard; the books were also saved. Temporary arrangements were at once made to restore telephonic communication with other countries, but it is estimated that many weeks, if not months, must elapse before anything approaching a normal service will be resumed.

Institution of Engineers and Shipbuilders in Scotland.—The official address of this institution will be 3 Elmbank Crescent, Glasgow, until November 16th, 1908, when the new premises at 39 Elmbank Crescent (directly opposite 3 Elmbank Crescent) will be ready for occupation.

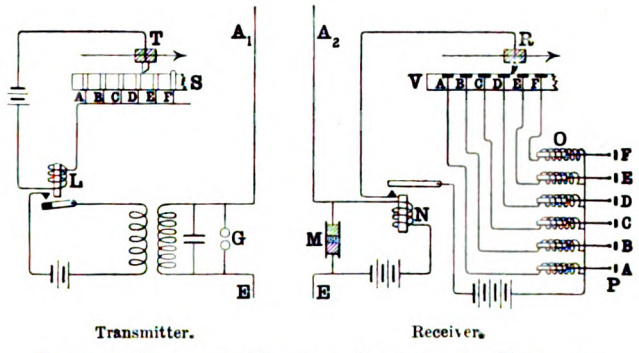
WIRELESS OPERATION OF LINOTYPE MACHINES

A DEMONSTRATION of a method of operating a Linotype machine, type-writer, or other keyboard apparatus by means of Hertzian waves was given by the inventor, Mr. Hans Knudsen, at the Hotel Cecil, London, on Thursday last. On page 648 of Vol. III. of ELECTRICAL ENGINEERING, we described the same inventor's system of transmitting photographs by means of Hertzian waves, and the present method of operating a keyboard is in some respects similar. The transmitting apparatus, a diagrammatic sketch of which is given below, consists essentially of a board S and a number of studs. The tops of these studs are normally flush with the surface of the board, but by depressing the keys of an ordinary keyboard, they are caused to project about $\frac{1}{4}$ in. above the surface. A travelling brush T makes contact with the projecting studs and at the same time depresses them to their original position. Whenever contact is made between a stud and the travelling brush T the relay L operates and a discharge takes place at the spark-gap G.

The resultant waves radiated from the aerial A_1 are received by the aerial A_2 and the coherer M responds,



KNUDSEN SYSTEM OF WIRELESS OPERATION OF KEYBOARDS.

thus causing the relay N to close the keyboard operating circuit. The receiving apparatus includes a board, V, on which are a series of contacts spaced the same distance apart as the studs on the transmitting board. These contacts are severally connected to electromagnets, O, each of which, when energised draws down a plunger and depresses a key on the keyboard of the type-writer or other machine which it is desired to operate. The key depressed will be that corresponding to the contact on which the travelling brush R rests, when the relay N closes the circuit. This travelling brush, however, is run synchronously with the travelling brush T of the transmitter, and consequently the key depressed will be that corresponding to the stud making contact at the transmitter. The method of working the travelling brushes synchronously was described in connection with the photograph transmitting apparatus; the chief point is that the transmitter sends out a series of waves at starting, and these waves affect a special coherer and relay circuit which starts the receiving apparatus. The machines are synchronised at very short intervals. In its present form the system, though interesting, can have no practical application, as it works extremely slowly. After printing a "d," for example, the brushes must travel over the whole alphabet of contacts before a "c" can be printed. Mr. Knudsen explained, however, that the apparatus exhibited was only meant to show the principle of the invention, and that a large number of modifications and improvements would have to be made before the system could be commercially applied.

A NEW DOUBLE SWITCH

THE accompanying illustrations show a novel form of double tumbler switch which has just been introduced by Messrs. A. P. Lundberg & Sons. This switch is a distinct novelty and should prove of considerable use for a variety of purposes where ordinarily two independent switches would be

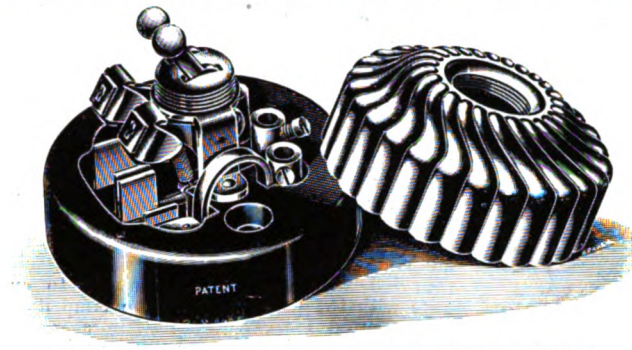


FIG. 1.—"TWINOB" SWITCH WITH FLUTED COVER.

used. The ordinary type combines, as shown in Fig. 1, on a circular base of standard diameter ($2\frac{1}{2}$ in.) two distinct switch movements of Messrs. Lundberg's well tried "pivot" type with a common terminal between them, arranged sufficiently close together to enable a standard cover interchangeable with other switches to be used. A small base type for flush work is also made, as shown in Fig. 2., and this is also of standard size. The construction embodies a new patented form of mica insulation for the attachment of the contact pieces to the arms, which is not only mechanically strong but cannot possibly be affected by heating of the contacts through overloading. The working of the switch is particularly easy and agreeable, and both arms can be depressed at once with no more trouble than in the case of an ordinary single switch. Any form of cover, locked or otherwise, can be fitted, and the visible metal parts can be supplied with several different styles of finish.

Among the various uses to which the switch can be put are the control of two groups of lamps, separately or together, and it will be readily seen that where a large number of combinations are required a great economy in the number of switches is obtained, and the distribution boards can be reduced to half the size. They can also be used with advantage for radiators with several lamps and in certain circumstances as two-way

FIG. 2.—"TWINOB" FLUSH SWITCH WITHOUR COVER.

switches, or in combination with two-way switches. It is also possible to connect them up with the two breaks in series and the contact arms pinned together for high voltages, and a further adaptation permits of their use as starting switches with one starting step for small motors. We are asked to state that these and other specialities of Messrs. Lundberg & Sons will be on exhibition at Manchester on the stand of their agents, the Sunbeam Lamp Co.

The Electrification of the Austrian Railways.—The work of securing the available water power for the electrification of the railways in the Alps is being continued by the State railway authorities in Austria. According to the *Elektrotechnischer Anzeiger* the water power of the rivers Oetz and Inn will be used for the power supply of the Arlberg Railway, the specifications for which have already been prepared. It is expected that tenders will be invited before the end of this year. An agreement has been made with the Austrian War Department whereby the railway authorities are obliged to keep the main lines in a condition suitable for steam traction, and also to keep in readiness the necessary steam locomotives, staff of drivers, and coal supply. The water power available in the south for the Brenner Railway is now being secured, and the engineering features of that line are being worked out. The electrification of this section, however, can only be proceeded with if the military authorities relinquish their demands with respect to the steam reserve. Conversion of the Vintschgau Railway and an extension to Landeck and the Engadin will probably be taken in hand before the Brenner line.

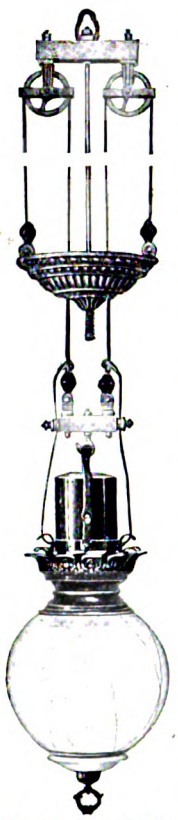
CATALOGUES AND PAMPHLETS RECEIVED

ARC LAMP ACCESSORIES.—Some new lists have been issued by the Union Electric Co. relating to arc lamp gear. One of these deals with guide attachments and cradles for outdoor lamps. In arc lamps hung on masts out of doors it is practically essential to steady the lamp between guide ropes or rods, so that wind pressure does not cause the lamp to swing, which would probably affect the burning of the lamp, or, when lowering, might lead to damage of the sleeve or breakage of the globe. The arrangements for this purpose comprise rope guides, on which by means of suitable attachments to the lamp framework, the lamp is guided up and down, and a special form of lamp cradle, in which the lamp is permanently fixed and the cradle provided with suitable attachments to engage with the guide ropes. The lamp itself is supported on two bell insulators in the cradle. A cable tension apparatus is used with lamps hung on high masts where arc lamp couplings are not employed. The object of this is to prevent the gradual breakdown of the insulation through the leads swaying in the wind; it can only be used with rope guides or cradle arrangement for the lamps. In one of the forms, the guide eyes are mounted on bell insulators, and therefore thoroughly insulate lamp from rope guides. The lamp is hung on the hoisting rope, through an insulating hanger, which encloses the porcelain insulator, and affords protection from wet.



UNION ARC LAMP COUNTERBALANCE GEAR.

The other list deals with hoisting gear, counterbalance weights, and other arc lamp accessories. The arrangement of one of the simpler patterns of counterbalance gear is shown in the accompanying illustration. As will be seen, the principal features are the use of a metallic suspension rope, which also conveys current to the lamp, and the provision of a counterbalance guide rod with spring buffer. Where greater travel is required, a double pulley arrangement can be used. Two forms of suspension rope are listed, one consisting of a plain flexible copper rope, and the other made up of tinned copper flexible rope to carry the current, and a steel wire suspension rope separately insulated, both cores laid up and braided together. The list also contains particulars of several of the more ordinary forms of winch and counterweight lower gear, strain releases, and arc lamp couplings.

Another list to hand from the company during the week deals with arc lamp resistance, of which a great variety, suitable for various patterns of lamps, are included.

EXTENSIBLE AND NON-SLIPPING LADDERS.—Messrs. J H. Heathman & Co., Parsons Green, Fulham, London, have sent a pamphlet of their well-known ladders, steps, trestles, scaffolds, trucks, &c. Important extensions are contemplated at the Fulham Works.

TIME SWITCHES.—Messrs. Venner & Co., of 6 Old Queen Street, Westminster, are issuing a new section of their catalogue relating to the "Venner" time switch, which, we are informed, has the distinction of being the only time switch approved by the Board of Trade. This particular section of the list contains particulars of the "B" type switch for currents up to 1½ amperes. A general description of the action of these switches was given in ELECTRICAL ENGINEERING, Vol. 1, page 730. The various forms which the switch can take include a simple make and break switch, a single pole change-over switch, and a five terminal change-over switch for two and three-phase circuits. These switches are particularly suitable for controlling double tariff meters, and are already in use on 70 or 80 different supply systems.

NAME PLATES.—Illustrated leaflets and cards from the Endolithic Manufacturing Co., of Pomona Buildings, Fore Street, E.C., represent a number of patterns of name plates for electrical purposes in ivory, ivorine, bone, and metal.

METAL FILAMENT LAMPS AND ELECTRIC LIGHTING SUPPLIES.—Several new pamphlets dealing with metal filament lamps and various electric lighting supplies have been issued by Messrs. Drake & Gorham, Ltd., 766 Victoria Street, S.W. The tantalum lamp section gives full particulars of the various standard sizes of these well-known lamps, from 16 to 50 c.p., for voltages from 65 to 160 volts, as well as the newer 25-volt tantalum lamps for train lighting or house lighting with small transformers. A large number of special fittings, adapters, and shades for these lamps are also listed, including a long series of special halophane shades and globes, outside lanterns, &c. Another section deals equally fully with Osram lamps in candle-powers from 25 to 400, and voltages from 100 to 250, as well as 25-volt, 10, 16, and 25 c.p. lamps, and several forms of miniature battery Osram lamps. A number of patterns of special shades and fittings for these lamps are included, and also small auto-transformers for running low-voltage lamps or ordinary alternating supply voltages. Further pamphlets deal with switchgear, fuse boards, &c., a special two-part porcelain insulator for surface wiring, steel callipers with dial reading, and a parallel motion drawing machine, replacing the use of tee and set squares.

DISTRIBUTION BOARDS.—A comprehensive new list of distribution boards, switches, and fuses, has been issued by Simplex Conduits, Ltd., embracing a considerable range of fuse-boards in various sizes in wood and iron cases, with and without switches to each circuit. Although all the boards can be supplied with ordinary open bridge fuses, it is noticeable that, in accordance with the prevailing tendency, especially with the higher voltages, all except some of the cheapest patterns are adapted

SIMPLEX DISTRIBUTION BOARD WITH ENCLOSED FUSES.

for use with enclosed fuses, of which several patterns are listed. The accompanying illustration represents a board of this nature in iron case, for six five-ampere ways, with D.P. enclosed fuses and S.P. switches. As an indication of the variety of boards included, we may mention that the prices range from 2s. 3d. for D.P. way, to 12s. for D.P. way in the case of iron-clad board switches for colliery and similar work. Other items dealt with in this catalogue are open and enclosed main switches, fuses, and fuse-boxes, &c.

TANTALUM LAMP FITTINGS.—Messrs. Siemens Brothers Dynamo Works, Ltd., are issuing a new leaflet relating to a

"SOLAR" FITTING.

series of "Solar" fittings suitable for tantalum "sun," and other spherical bulb lamps. The arrangement is shown in the

Digitized by Google

accompanying illustration, and can be used for single lamps, or a number of such fittings can be combined for the formation of very effective multiple light fittings suitable for public buildings, hotels, churches, &c.

IRON-CLAD FUSES.—Messrs. Tetley & Co., of Falcon Electrical Works, Bedford Street, Greengate, Salford, send us particulars of a special design of iron-clad fuses for voltages up to 600 volts. The body of this is of cast iron lined with a vitreous enamel, which prevents any possibility of earthing during rupture. The bases are of oiled slate, and all the sizes have a six-inch breaks. The list includes fuses for currents from 25 to 500 amperes.

OSRAM LAMPS.—A leaflet from the General Electric Co., forming an addition to the large Osram lamp catalogue, decsribes two new types of Osram lamp. They include a series of large lamps of 200, 300, and 400 c.p., for voltages from 100 to 260, which are of particular interest, owing to the fact that, not only are they cheaper in first cost than enclosed arc lamps of similar candle-power, but also cost less to run and maintain. There should thus be a considerable field for their use. The other new Osram lamps are at the other end of the scale, and are candle lamps with flame bulbs for running in any position. These are made for 10 and 16 c.p., not only in what is becoming the standard voltage for small transformers and independent plants, but also for 33 volts, so that they can be run three in series on 100-volt circuits in the often-used three-light candle fittings. Some 25-volt lamps in round bulbs are also listed.

ELECTRIC BELLS.—A new miniature catalogue of electric bells and accessories of a size suitable for the pocket, is being issued by the General Electric Co. The contents are very complete, and include a long series of bells, buzzers, relays, indicators, complete portable sets, pushes, batteries and other accessories. Some useful diagrams showing various methods of connecting up are also given.

ENCLOSED FUSES.—A card from the I.T.E. Electric Co, of 70 Finsbury Pavement, gives particulars of the "Shawmut" extended terminal lug type enclosed fuse, in which one terminal lug is extended and provided with a long slot, so that the same fuse can be employed in boards with screw clamp terminals of a variety of distances apart.

HOUSE-SERVICE BOXES.—British Insulated and Helsby Cables, Ltd., are sending out a collection of leaflets dealing with house-service boxes, &c. The patterns include boxes for a concentric main and two concentric services of the solid non-disconnecting type with plummer or ring clamps and two four-way disconnecting boxes with pavement frames and covers for single or three-core cables. Other house boxes are for a concentric main and two twin services, a triple concentric main and one three-core service, and a triple concentric main and one twin service. Another leaflet announces a new size of the well-known Downe patent "Prescot" feeder-pillar.

FUSE WIRES.—A list is to hand from British Insulated and Helsby Cables, Ltd., of aluminium copper lead tin and special "Prescot" alloy fuse wires supplied on reels in tin boxes, which can conveniently be carried in the pocket or in a wireman's tool-bag. These range from 1 to 300 amperes fusing current.

TRAMWAY BRAKES.—An illustrated brochure has been issued by the Electromechanical Brake Co., of West Bromwich, describing the Maley patent electromechanical rail brake. A full description of the working of this brake and of tests made with it on a car belonging to the Leeds Corporation, was given in Electrical Engineering, Vol. II., page 851. It will be remembered that its principal feature is the use of mechanical track brake-shoes, which can either be applied by hand or by means of the drag of an electromagnetic brake-shoe. Its action is in no way dependent on wheel-brakes, and it is intended for use equally as a service brake and an emergency brake.

THE NEW ENGINEERING LABORATORIES AT THE HERIOT-WATT COLLEGE, EDINBURGH

THE new engineering laboratories of the Heriot-Watt College, Edinburgh, have been erected on a site immediately behind the main building of the college, and occupy a ground area of nearly 12,000 square feet. They were formally opened on Wednesday, September 16th, by Lord Rosebery, who, after referring to the small number of day students attending the college, as compared with the large attendances of evening students, suggested that it would be to the benefit to both employers and apprentices if the latter were allowed to attend a few of the day classes as well as the evening classes.

An engineering laboratory and workshop was first instituted at the Heriot-Watt College in 1888, and it has since then done excellent service in the practical teaching of the principles of engineering. The Governors of George Heriot's Trust, assisted by the School of Arts, the Watt Institution, the Scottish Board of Education, and private subscribers, have been able to erect the present buildings and equip them with the most modern appliances. The teaching of practical engineering or handicraft is carried out in three workshops devoted to pattern making and working in wood, fitting, turning, all kinds of machine work, welding, forging, brazing, &c. These workshops are provided with various kinds of modern machine tools driven by electric motors. The design and arrangement of the experimental plant in the engineering laboratories has been carried out by Prof. Stanfield, Mr. A. R. Horne, and the other members of the staff of the Engineering Department. In the principal engineering laboratory, which is mainly devoted to the experimental study of heat engines, part of the space has been excavated to a depth of 8 ft. below the ordinary floor level upon which the engines are erected. The boilers, superheater, and measuring tanks have been placed in this space or pit, and all the water and condensed steam to be measured in connection with the various engines, &c., gravitates to these tanks, most of which are placed on platform weighing machines. The floors of the laboratories are intersected with wide pipe tracks covered with steel plates; these pipe tracks carry the water and other pipes from the various engines to the tanks or to the main drain which is below the floor of the boiler pit.

The outstanding feature in the new laboratory is the experimental steam engine which has been specially built by Messrs. Marshall, Sons and Co. At full load this engine is capable of developing about 90 h.p. It can be run condensing or non-condensing as required. The high and low pressure cylinders are 7 in. and 13 in. diameter respectively, with a stroke of 20 in., the normal speed being 120 revolutions per minute. The flywheel is placed midway in the space between the two cylinders, and the crankshaft is provided with flanged couplings on either side of the flywheel, so that by disconnecting one or the other of these couplings, either side of the engine may be run as a separate unit. Two governors of different types are fitted—one to each side of the engine, and a suitable reducing valve is provided to be used when the steam is supplied to the low-pressure cylinder direct from the boiler. Both cylinders and the receiver are completely jacketed, and can be supplied with either saturated or superheated steam; this supply is quite independent of the main supply to the engine. Suitable appliances are provided for measuring the steam condensed in the jackets. The surface condenser was made by the Worthington Pump Co., and is connected to an Edwards air-pump driven by an electric motor. The circulating water is measured by means of a Kennedy water meter. The power is absorbed by a rope brake, and suitable indicating gear is fitted to both cylinders. The temperature of the steam at various points will be taken by means of electric thermometers manipulated from a central switchboard.

Special attention is to be devoted to the experimental study of internal combustion engines, and this section of the laboratory includes a 8½-b.h.p. gas engine supplied by the Campbell Gas Engine Co., and arranged to work with either town or producer gas. The generator of the suction gas plant, from which the producer gas to supply the above gas engine is obtained, is mounted on a large platform weighing machine so that the consumption of fuel may be measured with accuracy; the connection between the generator and scrubber is made through telescopic pipe joints with water seals.

The laboratory is provided with complete apparatus for analysing flue and exhaust gases, also for determining the calorific power of coal, gas and oils. The applied mechanics laboratory is fully equipped with various kinds of apparatus and machines for illustrating and verifying the laws of mechanics and hydrostatics. A small hydraulic plant is provided for experiments on the flow of water through orifices and notches; also a small centrifugal pump driven by an electric motor. The strength of materials laboratory is provided with a 50-ton horizontal testing machine supplied by Messrs. Greenwood & Batley, and arranged for tensile, compressive, transverse, and shearing tests; also a Wicksteed torsion testing machine, and a complete cement testing plant. It is proposed to add later a 5-ton vertical testing machine. The smith's shop, which is not yet completed, will be provided with six hearths, and the usual tools for instructing the students in the principles and practice of forging and welding.

Proposed Electrification of the Russian Main Line Railways.—It is stated in *Elektrotechnik und Maschinenbau* that, according to the *Rus*, a congress of the Russian railway authorities will be held in St. Petersburg at the end of this month in order to consider the introduction of electric traction on the following main lines: St. Petersburg-Moscow, Kharkov-Sevastopol, St. Petersburg-Warsaw, and St. Petersburg-Wilna-Kiev-Odessa.

THE FIRE ON THE CITY AND SOUTH LONDON RAILWAY

Board of Trade Report

THE report of Col. H. A. Yorke and Mr. A. P. Trotter on the fire that occurred at about 5.40 p.m. on July 16th, about 40 yards south of Moorgate Street Station, on the City and South London Railway, has now been issued.

At the portion of the line upon which the fire occurred the permanent way is constructed with flat bottom rails weighing 80 lbs. per yard, which are attached to the sleepers partly by means of dog spikes, and partly by fang bolts and clips. The sleepers in the small tunnels are 7 ft. long, 12 ins. wide, and 6 ins. deep. They rest for a distance of about 12 ins. at each end upon concrete, which is built up from the iron lining of the "tube." The sleepers in the big tunnel are about 22 ft. in length, 12 ins. wide, and 9 ins. deep, and they extend right across from the up to the down line. They are supported at the ends and at two intermediate places on concrete pillars, built up from the lining of the tunnel. All the sleepers are of pitch pine "burnettized." The depth between the top of the sleepers and the lowest portion of the tunnel is, in the small tunnels, 1 ft. 3 ins., and in the large tunnel from 8 to 9 ft. The conductor rails are laid in the four-foot way at a distance of about 3 ft. from the running face of one of the rails, and there is a pathway through the tunnels consisting of two 9-in planks laid side by side between these two rails; the spaces between the rails at the cross-over road being covered with a similar planking as far as possible. When Moorgate Street was a terminal station, a signal-box, constructed of wood, was erected upon steel girders above the scissors crossing, close to the spot where the small tunnels join the big tunnel. When, however, the line was extended to Islington a new signal-box was built at the north end of and between the station platforms, and the old box in the tunnel was put out of use, but was not dismantled.

In 1900, when the extension from the Borough to Moorgate Street was constructed, the Board of Trade requirements in regard to prevention of fire upon tube railways were not in existence, nor did the Act authorising that extension contain any clause, such as is inserted in all modern Bills relating to "tube" railways, making it obligatory upon the railway company to submit all their plans and details of construction to the Board of Trade for approval before commencing work. Under the present regulations of the Board of Trade, issued in 1904, no wooden signal-box or other wooden structure is permitted to be erected underground on any "tube" railway, and the pathway between the rails is required to be formed of granolithic slabs or of similar material.

The fire appears to have been observed by the officials at Moorgate Street at about 5.40 p.m. As far as can be ascertained the driver of the down train, which left Moorgate Street for the Bank at 5.36 p.m., was the first person to notice it. When this man arrived at Bank Station he told the signalman what he had seen, and this man telephoned to Moorgate Street. About the same time the fire was observed by P. Kelly, who had shortly before come on duty at Moorgate Street to take charge of the lift machinery. He found flames issuing from the sleepers of the down road, and fetched some sand, with which he and others endeavoured to put out the fire. Although they did not succeed in completely extinguishing the fire, station-master Knowles considered that they had subdued it sufficiently to allow some trains to pass.

After the departure of the third train the fire broke out again, and Kelly, by direction of the station-master, switched off the current between Moorgate Street and the Bank. After the arrival of the next train at Moorgate Street it was evident that the fire could not be extinguished with the appliances available. Station-master Knowles therefore called upon the passengers, of whom there were about 120, to leave the train and ascend to the surface by the lifts. Knowles then ordered the station staff to go to the surface, and about the same time a telephone message was sent to the power house to cut off the current from the whole line. Before this was done, however, one of the cables "blew out." All traffic on the line was then stopped. As soon as the above steps had been taken the station-master sent the alarm to the fire brigade. The smoke was then very dense. The firemen descended to the platform, but were unable to proceed any further owing to the smoke. A second attempt made with the aid of smoke helmets, also failed. At 6.55 p.m. an attempt was made to enter the tunnel from Old Street Station, but by that time the smoke had reached this place, and was too dense to permit the firemen to enter. The firemen then went to Bank Station, where they had no difficulty in descending. They then proceeded along the down tunnel and reached the seat of the fire about 8.30 p.m. The water by means of which the fire was eventually extinguished was conveyed by hose along the tunnel from Bank Station to Moorgate Street.

It would seem that after the discovery of the fire at Moorgate Street Station some seven or eight minutes were occupied in the endeavour to extinguish it, during which time two trains had been allowed to pass over the spot where the fire had started, and no attempt was made to render the section dead between Moorgate Street and the Bank. And it was not until 26 minutes after the first alarm, that notice was given to the fire brigade, the result of this delay being that the smoke became so dense that the firemen, in spite of repeated efforts, were unable to reach the fire until 2 hours 50 minutes had elapsed after the outbreak. By this time the disused signal-box was completely destroyed, and there was then little difficulty in extinguishing the fire.

The report continues:—"It is not possible to say with certainty what was the actual origin of the fire. From the evidence given at our inquiry by Mr. McMahon, the electrical engineer of the company, it would appear that leakage of electric current has been known to occur between the power rail and the running rails, due to an accumulation of iron dust and carbon dust on the sleepers and insulators, the leakage being sufficient to set this dust and the upper surface of the sleepers on fire. It is possible that the present fire was caused in some such manner, or it might have happened that this dust was ignited by sparks from the shoes of a locomotive. The fire seems to have started between the last sleeper in the mouth of the down tunnel and the first of the long sleepers which span the cross-over. In the space between the two sleepers several electric cables were carried in a wooden trough, namely, a 0·125 square inch lighting cable, a cable connecting the conductor rail with a balancing dynamo, and a 20 circuit telephone cable. The depth below the sleepers in the tunnel, that is, as already stated, the distance between the upper side of a sleeper and the iron segments of the tunnel is about 15 inches; the depth below the sleepers in the cross-over is some eight feet. Having regard to the considerable time which elapsed between the discovery of the fire and any signs of electric arc on the spot, or opening of circuit breakers at the works, it seems probable that the fire did not originate from any defect in the insulation or in the continuity of the electricity cables, but began with a smouldering which may have developed into flames by the draught of passing trains. Although permanent way men walk through the tunnels every night, clearing away rubbish, the tunnels are extremely dirty, and some of the dirt is of a dangerous character, namely, that which consists of iron dust and carbon dust, the former from the brake shoes, wheels, and rails, the latter from the carbon brushes of the motors. In addition to this there is in some places a good deal of oil drippings. The insulators are said to be cleaned once in three or four months. This dust is inflammable. The coating of dust on a wire will burn with a smouldering glow, if ignited, and will, if fanned, say by the draught of a passing train, burst into flames. The sides of the tunnels and the wires carried along them are covered with it. When dust accumulates on an insulator it sometimes forms a path for an electric leak, which ignites it, and this may set fire to a sleeper. Such small fires have been experienced. When a driver sees one, he informs the station-master of the next station, who telephones back, and the driver of another train being warned, stops and extinguishes it with a brush. Pieces of waste have also been found on fire. Each locomotive carries a bucket of sand and a ten-gallon tank of water, which is connected with the compressed air tank, enabling a jet to be thrown. The dust to which reference has been made probably lay on the top and the sides of the trough carrying the cables, and on the sleepers, and became ignited either by an electric leak or by sparks from the shoes of the locomotives."

Repeated efforts were made to extinguish the fire by means of sand. This may have been effectual wherever it could reach, but the fire seems to have caught the sides and underside of the sleepers, and this could not be reached by sand or any other means. The fire was rendered less accessible by the planks which are fastened to the sleepers to form a footway.

About ten minutes after Mr. McMahon arrived at the engine-house the circuit-breaker came out on the lighting circuit. Linesman Nicholls says that as he approached the fire with a bucket of sand one of the cables "blew out." It is considered probable that this was a secondary effect, due to the burning of the cable, and that, as already suggested, the fire was not due to an excess of electric current. Had the large space in the invert below the cross-over, some 20 ft. wide, by 64 ft. long, and 8 ft. deep at the middle, been filled in and flush with the sleepers, it seems likely that the fire, confined to the surface, could have been extinguished by sand.

The fire spread laterally in both directions, but lengthwise only for a few feet. The electric lighting cable went to earth on a disused air pipe, on the east side of the down road, fusing a hole in it, and becoming itself severed. This was probably due to the burning away of the insulation. Two sleepers of pitch pine on this side were charred for about ¾ in. deep. The fire spread across the 25-foot tunnel, and four long sleepers were burned on the top and sides, but not sufficiently to render them unsafe. They were still in the road when the Inspectors visited the spot. The planking on the top of the sleepers over an area of 4 ft. by 20 ft. was also burned. Two new short sleepers had been added on this (the west) side since the fire. The insulation of a number of cables, both high and low pressure, and some large telephone cables between the two lines, had been burnt away

Digitized by Google

for some four or five feet, but the wires remained unsevered. As the flames and heat increased, the disused signal cabin above the cross-over road took fire, and was completely burned out. This probably helped the fire to spread, and was the cause of much of the smoke.

With a view to reducing the risk of fire, or, what is worse than fire, of smoke, the following recommendations are made:—(1) Considerably greater attention should be given to cleanliness; dust should be more carefully removed. (2) A liberal use of whitewash would enable any accumulation of dust to be detected. (3) The filling up of the inverts, particularly of the large tunnels, should be carried out. (4) No electric wires or cables should be carried below or between the sleepers, but should be neatly arranged along the sides of the tunnels, and all crossing of cables should be overhead. (5) The use of wood should be eliminated as far as possible; the planking and the wooden platforms should be replaced by slate or granolithic slabs. (6) On discovery of a fire, all traffic should be stopped in that section until the fire is completely extinguished. (7) Prompt notice should be given to the fire brigade."

THE BOURNEMOUTH TRAMWAY ACCIDENT

Board of Trade Report

MAJOR J. W. PRINGLE'S report on the accident which occurred on the Bournemouth Corporation Tramways on May 1st, in circumstances already reported in ELECTRICAL ENGINEERING, has now been issued.

In this case, a car was descending the incline from St. Michael's Church, Poole Road, into Bournemouth Square, viâ Poole Hill, The Triangle, and Avenue Road, when the driver (Wilton) lost control. The car attained a dangerously high speed, and eventually left the rails at the right-hand curve in Avenue Road, near the School of Cookery. It then crossed the left-hand footpath, and plunged down a bank into the private garden of Fairlight Glen House, where it came to rest on the steep wooded slope, lying on its right side. There were at the time from 35 to 40 passengers on the car. Of these, seven were killed, or died very shortly afterwards, and 26 were injured. The driver, who remained at his post, was also injured.

Car No. 72 was a double-deck (without top cover) bogie car, with eight wheels, and maximum traction trucks (large wheels leading). It weighed about twelve tons unloaded. The braking equipment included hand brakes and electro-magnetic track brakes.

The tramways in Bournemouth have the 3 ft. 6 in. gauge. Through the centre of the town, the lines are worked by electric traction on the underground conduit (side slot) system; outside the centre, overhead conductors with trolley arm connection was used. From the conduit pit in Poole Road to the scene of the accident is a distance of about 460 yards. The route winds considerably, and has continuous falling gradients.

It appears that on the day of the accident the car was driven by several different men. One of them (Copelin) took charge at 1.14 p.m., and at 3 p.m., in trying to reverse from No. 1 end, he locked the controller, and was unable to drive any further from that end. Eventually, by cutting out one of the motors, he was able to drive the car from the rear (No. 2) end into Parkstone Depôt. He reported that No. 1 controller was out of gear, and he could not use power from that end. Inspector Rushton examined the controller, and found the motor barrel out of position. He threw it out of gear, re-adjusted the barrel, and replaced the pinion gear, which had overridden. He then tested the controller by means of the handles, and found it worked properly. At 3.30 p.m. Copelin again took out the car. He had previously taken it twice down Poole Hill, and on both occasions he found the magnetic brake working properly. At 5.20 p.m. driver Wilton took charge of the car. He drove it from No. 1 end westward to the terminus at Poole, where he arrived about 6.8 p.m. He used the magnetic brake on this journey in descending Constitution Hill, and found it worked perfectly. About 50 yards from the terminus he shut off power by moving the large controller handle into the "off" or neutral position. After coming to a standstill, he brought his small handle or reversing key at No. 1 end from the forward into the "off" position. He then removed both handles, and took them to No. 2 end. He had no difficulty in doing this, and noticed nothing unusual in the movement of the handles. It is not possible, owing to the interlocking, to remove either of the handles until the pointers of both have been brought round into the "off" position as indicated on their respective dials. Wilton left the terminus at Poole, on his eastward journey to Bournemouth, about 6.10 p.m., driving from No. 2 end. As far as the conduit pit in Poole Road, about 4½ miles from the terminus, the journey was uneventful. No emergency stops were made, and there is no steep decline, so that Wilton is certain that he did not use the magnetic brake on this return journey. The car was brought to rest at the conduit pit, and the plough attached to the underground conductor. Wilton re-started the car, by using one or two notches of power, until a speed of three or four miles an hour was attained. Power was then shut off, and the car allowed to run a little distance. He applied three notches of magnetic brake about 65 yards from the conduit pit. There was no effect. He worked further notches on the brake side, and used sand, but there was still no effect. By this time the car was close to the usual stopping place at Par's Corner, and had attained a speed of ten or twelve miles an hour. He realised that the brake had failed, but was so confident that it was only a temporary failure that he brought his controller handle from the brake into the "off" position, and allowed the car to run freely round Par's Corner. He then re-applied the magnetic brake in the same manner, notch by notch, but again without effect. A little more than half way between Par's and Robson's corners, *i.e.*, about 280 yards from the top of the hill, Wilton applied his reversing power, by bringing his controller handle into the "off" position, moving the reversing key into the backward position, and then using power, notch by notch, as far as the fifth. This had no retarding effect, although the automatic canopy switch was blown, and the car had attained a speed of 20 to 25 miles an hour at Robson's Corner. Wilton then used his hand-brake, which he had held in position ready to apply it all down the hill, but the speed was so great that there was little or no retardation, and the car left the rails on the curve above Fairlight Glen House, as has been described, about 460 yards from the starting point at the top of the hill. Wilton's explanation for relying so long upon his magnetic brake was that on another occasion, about a year previous, the magnetic brake failed the first time he tried it, but worked beautifully on the second attempt. If he had known that the magnetic brake was not to be relied on, he could have taken the car down the hill in safety with the hand brake only.

Sections of the rails at the point of derailment show that the wear on the running edge of the left-hand rail amounted to about one-half of the original vertical distance between the head of the rail and the bottom of the groove. There were clear indications also that the flanges of the left-hand wheels, owing to the check on the inner rails, and the wearing down of the head of the outer rail, were riding on the bottom of the groove, two very clear scores being apparent. On May 14th certain trials were made on this particular curve, and speeds up to twelve to thirteen miles an hour attained by different cars without derailment. These trials prove at all events that, notwithstanding the large amount of wear on the rails in proximity to the site of the accident, as regards speed, there was a considerable margin of safety beyond the authorised limit of six miles an hour, provided the wheel flanges were in fair condition. At the same time, it is not possible, thinks Major Pringle, to avoid the conclusion that the worn condition of the rails at the point of derailment and of the flanges was to some extent a contributory factor in the case.

Major Pringle continues:—"I examined car No. 72 on the afternoon of May 2nd, before it had been moved from the position it occupied after the accident. It was then lying on its right side on the embankment. The hand brake was applied, and the sand valves and sand pipes were in order. At No. 2 (leading) end both handles were in position on the controller, the reversing key being in the "backward" position, and the large handle at the last (seventh) brake notch. No. 2 controller as regards contacts, fingers, mechanism, &c., was in good condition, and the movements of the large handle and reversing key actuated the barrels, and made contacts with the fingers in the proper manner. I found one of the leads attached to the coil of the off rear magnetic brake shoe broken, the brake being of old standing; the insulation of the other lead to the same coil was damaged. Inside the car the leads to this shoe were disconnected. Only three out of the four magnetic shoes were, therefore, available for use. So far as I could judge, the adjustment of the shoes was correct, and the release springs were in working order. There was some indication of 'flats' on the treads of some of the wheels, but the marks were all so slight that it was evident that the wheels could not have skidded for any appreciable distance on the journey down the hill. At my request all the electrical and magnetic circuits and earth connections were tested for continuity by Mr. Bulfin, Borough Electrical Engineer. All were found correct with the following exceptions:—Rear (No. 1 end) off magnetic shoe coil, the lead to which (as described above) was found broken; the earth cable to the case of No. 1 motor was found torn away from its socket, the severance in this case being clearly the result of the overturning of the car.

"To make these tests, the cover of No. 1 controller was removed by Mr. Lait, Depôt Superintendent, and foreman Robinson, on the evening of May 2nd. They found the reversing or motor barrel of this controller was not in its proper

Digitized by Google

'off' position, but midway between 'off' and 'reverse,' and that there was contact made with several of the reversing fingers. The fact that, when Wilton lost control of the car, the reversing barrel at No. 1 end was making contact with the reversing fingers, explains the failure of both the magnetic brake and the reversing power. The effect of this contact (with this type of controller), whilst the car was being driven from No. 2 end, would be to short circuit the armatures of the motors, and prevent the generation of current by the motors. Similarly there would be no retardation when the reversing key was placed in the backward position, and the controller handle used in the highest power notches." This was confirmed by experiments with another car.

"Mr. Turner, electrical engineer to the British Westinghouse Electric Co., gave evidence to the effect that, when he examined, at the request of the Corporation, the controllers of car No. 72, there was a marked difference in their condition. The gearing and motor barrels of No. 2 were in good order, and no slack movement was observable beyond that which is always to be found in similar gearing. The mechanism of No. 1 controller was in a very slack condition, one of the motor barrels was so loose on its spindle that contact could be made with two or three fingers on either side by moving it with the hand. Granted contact with two fingers on the reverse side at No. 1 controller, the brake effect and reversing power when applied at No. 2 controller would be neutralised. It was possible, by sharply swinging round the controller handle at No. 1 end into the off position, to make contact on the reverse side, without any overriding of the teeth in the gearing, and this could occur without the knowledge of the driver.

The looseness in the working of No. 1 controller may be accounted for by the fact that the original reversing barrel, supplied with the controller in 1906, had been replaced by another and older barrel, which had seen previous service. This barrel, besides having been subject to more wear and tear, may possibly have fitted the new controller with less accuracy."

The report contains the following general conclusions on the whole case :—

(1) The initial cause of the car getting out of control on this occasion was the incorrect position of the reversing barrel of No. 1 controller at the rear end, which rendered useless all the electrical braking equipment whilst the car was being driven from No. 2 controller. (2) Consequently the only available means of checking the speed of the car down the hill was the hand brake with its wheel blocks. These were in good order, and if Wilton had recognised at an earlier moment—say, when he was rounding Par's Corner—that the magnetic brake and reversing power were useless, he could, by careful management of the hand brake, and the use of sand, have negotiated the remainder of the decline in safety. (3) The incorrect position of the reversing barrel was not, in my opinion, due to mismanagement of the handles by the driver, but to looseness in the mechanism of the controller, due to wear and tear and want of proper maintenance.

Wilton's failure to recognise more quickly that his electric brakes were useless does not, in my opinion, amount to more than an error of judgment; and he deserves credit for remaining at his post till the last moment. To fairly apportion the responsibility for permitting the car to go on service in such an unreliable condition is a difficult matter. The system of stabling cars indiscriminately at any of the four depôts, is largely at fault. The particular controller must for some time past have been in an unreliable condition. That its condition was not discovered by any of the controllermen, foremen, or Inspector Rushton, argues either insufficient examination or want of knowledge.

Major Pringle also calls the attention of the Corporation to the following matters :—

(*a*) No cars should be permitted to be on service without their full brake equipment. Mr. Barber has had trials made to show that the stopping effect on a large car with four magnetic brake shoes in use is but little better than with three only. This may be admitted, but public safety demands the highest possible efficiency, and not the second best. It is only on the understanding that the full equipment is available that the Board of Trade license working. In this particular case there were no magnet coils in store, and there was no evidence to show how long the shortage existed. But if the Corporation had given the necessary authority for keeping such necessary articles in store, the responsibility rests with the Depôt Superintendent and his staff.

(*b*) The position of the sand pipes in the large cars can be improved. On No. 72 they were placed 24 inches from the wheel contact. Dry sand delivered at such a distance will of necessity fall clear of the rails on a curve, and even on a straight road be more liable to be blown away from the desired spot by any current of air. The distance should be reduced by one-half at least.

(*c*) The rails on the curve where derailment took place require to be renewed, preferably with a wider groove than that originally used. I have referred to the worn condition of these rails, and recognised that there was sufficient margin of safety for the speed authorised. But all curves at the foot of long steep declines are danger points, and for this reason it is of importance that the rails on such curves should be carefully watched and replaced when they show considerable signs of wear.

(*d*) As regards the magnetic brake, it is now generally recognised that it should not be reserved only for emergency purposes, and for descending steep gradients, but should be in common use. When used for coasting gradients, the common practice, as set forth in the Instructions to Motormen issued by the British Westinghouse Company, is to set the controller handle immediately to the last braking notch, and move it back as may be required. I see no reason why the practice in Bournemouth should be otherwise.

(*e*) The training of drivers is not given the attention it deserves. At most tramway centres a regular school is maintained for the training of men, which contains full scale models of all the electrical equipment and wiring on a car. Batches of selected men are put through a regular course, first in technical education, and afterwards of practical driving under a qualified instructor, and the men are examined, both in theory and practice. The method at Bournemouth of giving a conductor a permit to learn driving, during his spare time, from any permanent driver is not a satisfactory substitute.

(*f*) The organisation of the tramway department is open to criticism. So far there has been no regular manager at Bournemouth. The control seems to have been divided between the Borough Engineer, the Traffic Manager, and others. No one officer is responsible to the Corporation for the administration of the whole undertaking. This cannot be a satisfactory arrangement. I strongly advise the Corporation to make a change in the organisation, by selecting in open competition a properly qualified general manager, and giving him control over the whole department. The critical period for tramways is not during the first three or four years, when equipments, &c., are comparatively new. It is later on, when mechanism begins to wear out, and renewals have to be made. Previous experience of some length is then of first importance.

Finally, the following alterations and additions to the regulations now in force are recommended :—(1) The compulsory stopping-place in Pool Hill on the downward journey should be at the arc lamp-post before reaching the Pembroke Hotel. (2) So long as the magnetic or other track brake is not used for ordinary stops, it shall be applied, to test its effectiveness, before reaching any steep gradient down which the brake is used for coasting. (3) All controllers at every terminus, before the handles are removed, shall be opened and the barrels examined for their proper "off" position.

We have received copies of several communications from officials of the Bournemouth tramways commenting upon the report which have been submitted to the Board of Trade.

Mr. F. W. LACEY, M.Inst.C.E., writes as follows regarding the curve where the derailment took place :—The authorised speed round this curve is six miles per hour, and the track as laid is capable of taking any car in fair working condition safely round at a speed of from 12 to 16 miles per hour. I do not attach so much importance to the actual wear of the outer rail, as the grinding effect of the flange of the wheel so alters the original section of the head of the rail in such a very short time and in such a manner as to render the flange of the wheel practically ineffective as a means for keeping the car on the line after the first few weeks, and especially is this the case where the groove of the rail is narrow. Major Pringle now recommends a wider groove than that orignially used, and in this connection I should like to call the committee's attention to the correspondence between myself and the Board of Trade previous to the construction of these curves. This correspondence proves that on behalf of the Corporation I pressed the Board of Trade to allow an extra width of groove round all sharp curves. The Board, however, notwithstanding my repeated appeal, insisted that the groove in the rails should not exceed 1¼ in., and the conduit slot 1 in. It is only fair to add, however, that it is practically impossible to construct this curve so as to make it safe for a run-away car to negotiate, because to do so the levels of the road would have to be altered so as to make it hardly safe for slow and ordinary traffic.

The use of magnetic brakes.

The cars were originally fitted with hand brakes and usual electrical brakes, but after the inspection of the line by Major Pringle in December, 1902, the Board insisted that the cars to be used in service on the Poole Hill should be fitted with track brakes (as I then understood the matter, because a very small length of that line exceeded a gradient of 1 in 14). As the trucks of the cars were so hampered with gear owing to the conduit system, it was impossible to fix a mechanical track brake, and the Committee were compelled to have recourse to an electrical track (or magnetic) brake as fitted, which the Board of Trade approved of.

Mr. Lacey also contends that electromagnetic track brakes are unnecessary in the service in question, and points out that they were added owing to the insistence of the Board of Trade. The service on Poole Hill was worked with the hand brake only, for a period of six months, with very satisfactory results.

Digitized by Google

Mr. Lacey continues :—The organisation of the Tramway Department is seriously criticised by Major Pringle, but I would point out that he took little or no evidence on this point. Mr. Barber, the traffic manager, has the sole control of the whole system, so far as the public safety may be said to be concerned, with the single exception of the maintenance of the track, which is in my charge. Mr. Barber reports direct to the Tramway Committee, and receives his instructions direct from that Committee on all matters affecting the stores, maintenance of rolling stock, overhead equipment, traffic management, and working generally.

The Borough Electrical Engineer is responsible for the supply of the current in exactly the same way as the Electricity Company is responsible for the supply of current on the Poole and Christchurch lines. I cannot see why it is necessary for the Traffic or General Manager to have control over the tramway generating station any more than he should have control over the company's stations at Branksome and Christchurch, and I am of opinion that it would be inadvisable to increase his responsibilities in that direction. Wth regard to the maintenance of the track, I am of opinion that if for no other reason than to avoid dual control of the highway it is advisable for the Borough Engineer to maintain the track. It is obviously his duty to construct it, and with all due respect to electrical engineers, I think that the life-long experience of borough engineers should be at least as valuable as the comparatively recent exprience of electrical engineers or tramway managers in such matters. At the same time I admit the necessity for carefully considering any suggestion of the Traffic Manager as to repairs, and especially so in connection with all danger points.

Major Pringle states that the critical period for tramways does not come until three or four years. I do not think any practical tramway manager would agree with this statement, as it is common knowledge that the equipment, &c., commence to wear out, and renewals have to be made well within the first six months. I cannot refrain from stating that I think, quite unjustifiably and perhaps unintentionally, Major Pringle's observations are calculated to give the impression that the tramway system of Bournemouth is not a satisfactory one. The fact remains, however, that until the unfortunate accident in question, and notwithstanding the very difficult nature of the track and complications arising by reason of the combined overhead and conduit systems, no serious accident had happened during the previous six years in which the tramways had been in operation.

Mr. I. BULFIN, Borough Electrical Engineer, writes :—The permanent way was laid in 1902, and new conduit guard rails were laid round the curve of Fairlight Glen in 1906, and the outer track rail was raised from one to two inches. The usual life of a permanent way is from 11 to 15 years, and it was considered that the rails round this curve were in a satisfactory running condition.

Mr. C. BARBER, Engineer and Traffic Manager, writes as follows :—With regard to the condition of the controller, I regret that I cannot agree with Major Pringle's suggestion that it must have been in an unreliable condition for some time past. I, myself, on the Sunday after the removal of the controllers from the disabled car to the depôt, closely examined both of them for this very matter of slackness, and found that, with the exception of one finger which was bent (during removal), I could not make the reversing barrels come into contact in the manner suggested at the inquiry. I am convinced that the incorrect position of the reversing barrel was due solely to the straining in the afternoon, inadvertently it may be, of the mechanism of the gear which connects the main and reversing barrels.

The Westinghouse Company's representative at the inquiry admitted that some of the rocker arms (malleable castings) which formed part of this gear were, during the making of the controllers in the works, knocked into shape, if they did not happen to be of the correct shape to fit a particular jig. This original bending into shape would undoubtedly have the effect of making them more liable to bend again in use when subjected to strains such as those to which they are subject when the controller is worked quickly. That the particular casting in question has been dealt with as above-mentioned may be inferred from the fact that it bears marks indicating that it has been hammered. I think it to be regretted that the Westinghouse Company in the controllers made at Manchester, of which this particular controller is one, have made a radical alteration in the shape of the tooth of the gear. The American made controllers which are fitted to the original cars have proper mechanically shaped teeth, but those supplied with the last ten cars have the top corners of the teeth rounded off. The natural result is, with rounded teeth, that the gears are more liable to ride over one another, and so cause the reversing barrel to be placed in an incorrect position with the contacts touching when the main handle is in the "off" position. This is what, according to Inspector Rushton's evidence, happened in the afternoon, and, in my opinion, was repeated before the accident.

It is a matter of regret that Major Pringle did not make any examination of this controller while on the car at the time of his inspection on the day after the accident, when he could have satisfied himself as to its exact condition then and there, as it had not then been touched.

I would state that the defects in this controller were matters which I personally pointed out to Major Pringle in private conversation previous to the public inquiry, explaining to him the electrical results arising from the incorrect position of the reversing barrel of the rear controller when the car was being driven from the other end.

Further, I practically demonstrated to him the effects resulting by driving a similar car with the rear controller made similarly defective.

Major Pringle, in the course of his inquiry, referred to a printed card issued by the Westinghouse Company, headed "Rules for the care of Westinghouse Magnetic Brake Equipments."

This card has been hanging up in the depôt.

Under the heading of "Controllers" the Westinghouse Company have not a word to say upon the importance of making sure that the contacts of the reversing barrel do not touch when the barrel is in the "off" position.

Mr. Barber calls attention to the fact that, in a special notice displayed on each depôt notice board in June, 1906, as the result of disasters in other towns, he called attention to the necessity of every precaution being taken to avoid such an occurrence happening here, detailing the parts of the equipments requiring especial attention. In this notice are the words : "Every care must be taken that the reversing drum does not make 'contact' when in the 'off' position."

He also calls attention to Col. Yorke's report of the Glasgow accident in April (ELECTRICAL ENGINEERING, Vol. III., p. 973), due to a similar cause, and suggests that the Board of Trade be asked to advise the Westinghouse Company to notify the various tramway systems concerned of the danger which is present with this particular type of controller, resulting from contact inadvertently being made.

He then explains the arrangements adopted for the "stabling" of the cars, which is claimed to have the advantage of flexibility and to lend itself readily to traffic requirements. In order to adopt the method advocated of the same cars always being attached to the same depôts, a much more rigid and less economical system, from the traffic point of view, would be necessary.

With regard to the maintenance of equipments, he continues :—The course adopted for the maintenance of the cars has been that, when the cars are stabled in each depôt for the night, a staff of men is employed to regularly and systematically examine and attend to the many and various details of the car equipments. Each driver gives particulars of any defect noticed in the behaviour of his car upon a report sheet carried by him. These sheets the foreman at each depôt receives, and he, himself, examines any such defect reported. Each man in the depôt staff has his appointed part or parts of the equipment assigned to him. For example, the various parts of the brake gear are nightly attended to by the same man, the sand gear by another, the ploughs by another, and so on. Twice a week the controllers are examined, the commutators cleaned or armature bushes attended to, each by regular men. Each night the depôt foreman fills in upon a special report sheet (on which are printed suggestively the regular routine details to be attended to), all particulars of the work done upon the various cars. The various report sheets are daily examined by the depôt superintendent, who is thus kept advised of the work done and matters reported requiring attention. Periodically cars have to be taken to the central depôt, where the various details of the equipment are overhauled and all repairs and renewals beyond the ordinary everyday adjustments, and small replacements are carried out.

Mr. Barber also remarks that with regard to the car being in service with only three brake shoes in action, that a stock of spare magnets was usually kept in reserve, but owing to a period of wet weather and an unprecedented fall of snow just previous to the disaster, this stock had been exhausted by replacements.

With regard to the manner of using magnetic brake, Mr. Barber writes as follows :—The magnetic brake has not been kept for emergency purposes only, but has been in common use for service stops. As to the method of using it when about to descend a hill, I would remark that I was aware of the printed card of the Westinghouse Company relating to its use. As the result of failures on previous occasions, the London manager of the Westinghouse Company himself came down to me, but never took exception to the manner of using it nor mentioned the method of application now recommended, nor did their representative who followed him, although he spent some days in Bournemouth watching the drivers applying it. I find that the largest system and the system that is generally considered to be the most efficient in the country, namely, Glasgow, follows the same practice as is in use in Bournemouth.

Mr. Barber continues :—Major Pringle's description of the method adopted in Bournemouth for training drivers is not complete. I would point out that after learning to drive in the charge of an experienced driver on the road, the learner driver is tutored by the Chief Inspector on the roads adjoining the car sheds in the method of using his brakes and making emergency stops. In addition to this, the men gain a practical

Digitized by Google

knowledge of the various parts of the equipments through acting as assistants to the regular depôt staff engaged upon the overhaul and repair of the equipments when on relief duties. With regard to technical schools, it appears that the largest systems in the country, namely, Glasgow, London, Leeds, &c., have lately adopted some such system for the training of drivers, but in the case of the great majority of systems it does not appear to be adopted.

With regard to Major Pringle's statement that "the critical period of tramways is not during the first three or four years, when equipments, &c., are comparatively new. It is later on when mechanism begins to wear out and renewals have to be made." I would remark that my experience goes to prove far different to this, as from the very commencement mechanism requires attention and adjustment, and many parts of the equipment require renewal within the first six months.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN the Editorial Notes of the September number of *Electrochemical and Metallurgical Industry* the question of cheap water power against steam power for electrochemical processes is discussed. It is pointed out that although cheap power is a very important factor, it is not all-important. Cheap power in an inaccessible region where labour is difficult to obtain and where there are no transport facilities, would not be a sufficient incentive to put down an electrochemical plant. The majority of the large electrolytic copper refineries of the United States have been established near to New York City, and are operated by steam power. What the electrochemist requires is cheap power and good freight and labour conditions. Central stations have serious load depressions during a great part of the day, and only in the evening under normal conditions do they have a peak load. If these depressions can be filled in so that the power curve is a straight line their prosperity would be very materially increased. But if they are to fill in their gaps by supplying power to electrochemical works, it follows as a necessary corollary that during times of peak load the electrochemical works must go without power, or must take very much less than at other times. Now most electrochemical processes require to be carried on continuously, and would not pay when worked intermittently. It is pointed out, however, that certain furnace processes, such as carbide, carborundum, graphite, &c., can quite easily be, and often are, worked intermittently. It would thus require careful organisation and a certain amount of give and take between the central stations and the electrochemical works in order to work profitably. Electrolytic industries, such as copper refining, manufacture of chlorate, and so on would find it more difficult to manage, because for economy's sake it is necessary to work continuously. One hardly likes to suggest that during peak loads they should fall back upon accumulators to supply the deficiency, because a large storage battery is a very expensive item, and the repair item is considerable. But at the same time it is good that the subject should be kept forward, for, as the Editor remarks, "Central station men and electrochemists have not yet come to a sufficient understanding of their mutual needs."

In the same number there is an interesting article by R. L. Whitehead upon Electrolytic Refining of Gold, Silver, and Copper at the United States Mint in San Francisco. All the American Mints have gradually been equipped with electrolytic refining plant. Philadelphia was the first, then Denver, and now the sulphuric acid process which has been used for 30 years at San Francisco has been completely replaced by the most modern and up-to-date plant installed in any mint. Both at Philadelphia and Denver the electrolytic process has been found more cleanly and economical than the older methods.

In the Tank Room thirty specially designed Royal Berlin porcelain tanks, 18 in. long, 13 in. wide, and 12 in. deep, are arranged on a stone table. The tanks are arranged in two rows of fifteen each. The circulation is obtained from a porcelain trough, supplied by a special jar, which receives the discharge from a porcelain plunger pump, especially made to withstand the chemical action of the gold chloride solution containing free hydrochloric acid. The tanks are so constructed that the solution enters at the back and is drawn from the bottom. By this means the heavy gold chloride which sinks to the bottom from the anodes is constantly removed, and is carried to the pump tank to be again circulated. This method of circulation is in striking contrast to the propeller circulation employed in the other mint refineries. There are many objections to the propeller system. The violent agitation is practically confined to one place, leaving the ends of the tank with very little circulation, the chloride of silver formed at the anode is dislodged and floats about in the tank. Some may adhere to the cathode and become covered up with fresh gold deposit. The slimes swirl about in the tank, and consequently more frequent stoppages for cleaning are necessary. The anodes and cathodes are placed ¾ in. apart, and only 1 volt is required per tank to maintain a current of 450 amperes. This represents a current density of 105 amp. per square foot of cathode surface, which gives a gold output in 24 hours of 650 to 675 oz. The best run for one week with 20 tanks was 13,500 oz. per day. The fineness of the melted cathodes averages 999·5. The purity of the anodes varies from 880 to 960 in gold. Anodes containing as much as 100 parts of silver have been worked successfully and have yielded gold of 999. The silver tanks are 24 in number, and are made of German earthenware, the circulating system being similar to that employed in the gold tanks. These tanks are 39½ in. long, 19½ in. wide, and 12 in. deep, arranged upon a stone platform supported by enamelled pillars. The anodes contain 300 to 333 parts of gold and not more than 100 parts base metals, the rest being silver. The electrolyte contains from 1 to 2 per cent. of free nitric acid, 3½ to 4½ per cent. silver, and small quantities of lead, copper, bismuth, and zinc. Owing to the anodes being very base, about 5 per cent. by volume of the electrolyte is drawn off every 24 hours, and an equal volume of solution rich in silver is added. The current density employed is about 50 amperes per square foot. The anode contact piece is cast into the anode slab, thereby ensuring good contact.

The foul solution drawn off daily is freed from silver by means of copper plates, and the silver thus recovered is made into silver nitrate for replenishing the electrolyte. The waste coppery solution is worked up for copper. The silver deposit runs uniformly about 999·5 fineness. The anode residue, mainly gold, is washed free from silver, melted, and cast into anodes varying in fineness from 920 to 950. In most refineries the foul silver solution is purified by precipitating the silver as chloride, and the copper present is run to waste. By precipitating the silver with copper plates, both copper and silver are saved.

For making gold chloride, anodes 990 fine are employed, and are hung in a solution of strong hydrochloric acid. The cathodes are of rolled gold, and are suspended in a porous pot containing hydrochloric acid, the whole being placed in the anode cell. A pressure of 5 volts is used, and a current of about 200 amperes is forced through the bath. Consequent on the cathode plates being of small surface for so high a current, considerable heat is evolved. This causes evaporation of the electrolyte, which therefore requires the addition of fresh electrolyte from time to time. Owing to the acid fumes the cells are placed beneath an acid-proof hood by means of which they are conveyed away. The copper recovered from the various solutions contains gold, silver, and platinum metals. It is treated electrolytically to obtain copper sufficiently pure for purposes of alloy, the platinum, silver and gold being obtained in the slimes. The gold is precipitated out with ferrous sulphate, and the platinum is thrown out together with the copper by means of scrap iron.

During three months' working of the refinery, 500lb. of copper was recovered from the gold operated upon. From this copper 112 oz. of platinum and iridium were recovered. The copper slimes produced a bar assaying 83 parts of platinum per 1,000 oz. This represents a concentration from 1,073,000 standard ounces of gold, which, supposing the platinum to be evenly distributed, would make less than one-tenth of an ounce of platinum per 1,000 oz. By ordinary methods this platinum would not be recovered. But here, by the mere refining of the gold and with very little extra expense, a metal worth about 90s. per oz. is recovered. The rest of the article, which is to be continued, is taken up with a description of the electrical plant, switchboards, &c.

Improved Services on the London Underground Railways.—Some improvements in the services on both the Metropolitan and District Railways are announced for October 1st. Instead of only Metropolitan trains making the complete journey of the "Inner Circle," the service is to be augmented by the addition of District trains. The new arrangement will obviate the necessity for sometimes changing at South Kensington between 8 a.m. and 9 p.m. From 30 to 34 trains per hour are to be run between Gloucester Road and the Mansion House during the busy hours of the day. The three-car trains now in use during the "slack" hours, which are often badly overcrowded, are to be changed to four-car trains, and an additional car will be placed on the five-car trains. Some further non-stop trains are to be run in the morning and the evening, and the 7.33 a.m. nine-car train from Barking, which is said to be the longest electric multiple unit train in the world, is to be further increased to ten cars. A similar train is also to be run from East Ham at 7.59 a.m. The length of these ten-car trains is approximately 500 ft. The improved services on the Metropolitan Railway include a ten-minute service to Harrow, and a six-minute service to Hammersmith. On Monday last, improved services were commenced on the Piccadilly, Bakerloo, and Hampstead Tubes. On the Piccadilly Railway the service during the busiest hours is every two minutes; on the Bakerloo it is every 1¾ minute. Every precaution is being taken to prevent delay; tickets can be obtained in strips of six, and the lifts are run as far as possible in connection with the trains.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Sept. 17th, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

12,072. **Electrical Marine Propulsion.** H. A. MAVOR and MAVOR & COULSON, LTD. A proposal to build the frames of the polyphase motors, used on ships for propulsion, as a part of the structure of the ship. For example, the stator stampings may be built up inside a special bulkhead having stiffening pieces extending to the deck and frame of the ship. This arrangement is said to reduce the weight of the motors, and to permit of the use of small air-gaps in consequence of the great rigidity obtained. Two claims, three figures.

16,781. **Train Lighting System.** O. SCHALLER. A method of obtaining a constant pressure from a generator driven at a variable speed. Two sets of machines, or two machines with double armature windings, are used, the one coupled to the variable speed shaft, the other driven electrically. The connections are such that the sum of the speeds of the two machines or sets of machines is constant. Two of the armature windings, one of each set, are connected in series across a battery, and the other two are connected in series across the load. The fields of the machines are also connected in series respectively, and are across the battery terminals. The speed of the free running set automatically adjusts itself so as to maintain a constant load pressure. Six claims, five figures.

19,562. **Suspension of Metal Filaments.** DEUTSCHE GASGLÜHLICHT ATK. GES. (AUER GES.). The filaments of metal filament lamps are generally made in the form of a loop, and are supported at the bend of the loop. Trouble has been experienced owing to the adjacent sides of the loop coming in contact, and thus short-circuiting a portion of the filament. To remedy this defect, double suspending hooks are proposed. These are so constructed that they prevent too sharp a bend by giving two points of support at the bend. Four claims, four figures.

20,068. **Combined Wall-plug and Switch.** J. W. HUNTINGTON. An improvement in that type of wall-plug in which the operation of inserting the plug pins is caused to close a double-pole switch contained in the socket. A separate push-rod is provided on the plug, and this rod closes the switch as the plug is pushed home. The switch contacts are not made before the pins are some distance in the socket. A quick break of the switch is obtained, which is independent of the speed of withdrawal of the plug. Three claims, three figures.

20,495. **Centrifugal Governor for Single-phase Motor.** H. C. E. JACOBY. The centrifugal governor mentioned in the description of the Jacoby variable-speed single-phase motor given in ELECTRICAL ENGINEERING, Sept. 10th, page 383. Six claims, three figures.

22,211. **Cases for Accumulator Cells.** E. L. OPPERMANN. (X. ELECTRIC ACCUMULATOR CO., LTD.) A container or casing for the cells of a secondary battery, consisting of a sheet steel body about 1/16-in. thick, lined with ebonite. Such a case is said to be cheaper and stronger than an all-ebonite case. A special form of construction and a ventilated lid are also described in the specification. Six claims, six figures.

22,526. **Armature Winding for Single-phase Motor.** H. C. E. JACOBY. The armature winding of the variable-speed single-phase motor described in ELECTRICAL ENGINEERING, Sept. 10th, page 383. A winding pitch of approximately seven-tenths of the pole pitch is adopted, and the brushes are so fixed that the algebraical sum of the alternating fluxes passing through the coils under commutation is practically zero. This prevents the generation of heavy currents in the short-circuited coils. It is further stated that by the above arrangement there are zones on the armature in which the current is flowing in opposite directions in adjacent conductors, and that the reactance of the coil under commutation is thereby considerably reduced. The speed of such a motor can be varied by shifting the brush position, as sparkless computation is said to be attained over a wide range of brush position. Three claims, four figures.

24,992. **Armature Winding for High-speed Direct-current Generators.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). In large direct-current high-speed generators, the induced voltage per coil of the armature winding may be too high to impress on adjacent commutator segments if good commutation is to be obtained. According to the present invention, a number of armature windings connected to successive commutator segments are employed, and connections from each end of each coil of each winding are made to the opposite end of a coil of another winding, these points being at an equal potential. It is claimed that the connections may be carried beneath the armature core without introducing detrimental self-induction, as the adjacent connections neutralise each other. By this means the voltage between adjacent segments can be reduced to a fraction of the voltage per coil. Three claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Names in brackets indicate communicators of inventions from abroad.
Summaries of some of the more important of these patents will appear in our next issue.

1907 Patents

12,342, BURRY. Printing telegraph receivers.
12,386, MAVOR, MAVOR & COULSON, LTD., & BILES. Electrical propulsion of marine vessels.
13,073, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Alternating-current motors of the repulsion type.
17,474, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Alternating-current commutator motors.
19,282, POLLAK. Apparatus for strengthening weak current impulses, applicable to telegraphy and telephony.
19,570, GARRARD, & FERRANTI, LTD. Electricity control relays.
19,672, GES. FÜR VERWERTUNG CHEMISCHER PRODUKTE. Manufacture of metal filaments.
19,699, ALLGEMEINE ELEKTRICITÄTS-GES. Signalling systems.
19,883, BRITISH THOMSON-HOUSTON CO., CLINKER, WEDMORE, & WOODBRIDGE. Protective devices for alternating-current distribution systems.
20,227, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Manufacture of refractory bodies.
22,285A, SILVER. Supporting or carrying of electrical machines.
22,728, JUSTICE (*Rowland Telegraphic Co.*). Balancing the lines of electric circuits in duplex systems of telegraphy.
23,311, CLARK. Electro-mechanical means for controlling belt gearing.
24,103, LAKE (*Auto Pump Co.*). Electrical indicators for indicating water levels.
25,752, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric cooking apparatus.
25,922, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Manufacture of insulated electric conductors.
27,278, MAGLIETTA. Automatic signalling apparatus for trains.
27,936, LÜTHI. Time switches.

1908 Patents

327, LERTOURNÉ. Apparatus for comparing the speed of two or more machines.
2,685, FESSENDEN. Receivers for wireless telegraphy.
4,368, SYKES. Electrical operation of railway points.
5,317, COWPER-COLES. Apparatus for electrolytically etching or depositing metals upon metallic surfaces.
5,374, DAVIDSON. Portable electric resistance for use with surgical lamps.
8,286, BOULT (*Voigt & Haeffner Akt.-Ges.*). Automatic switching devices.
8,771, SIEMENS SCHUCKERTWERKE GES. Energy storing arrangements, applicable to hydraulic systems for the transmission of power.
9,449, FRIED. KRUPP AKT.-GES. GERMANIAWERFT. Electrically-operated heating devices.
10,851, SHEPPEE. Motors.
12,630, BOURGEOIS & BOURGEOIS. Pocket electric lamp.
12,968, KUZEL. Manufacture of filaments from refractory materials in the colloidal state.
14,805, FREEL. Antiseptic attachment for telephone mouthpieces.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

1908 Patents

16,164, SIEMENS & HALSKE AKT.-GES. Spring switches for electrically setting railway points and signals.
17,533, TRIN. Electrical accumulators.
17,752, LULING. Electric switches.
17,852, DUPONT & HARLÉ & CIE. Continuous-current motors.
17,858, WILSON & CLAFLIN. Signalling systems.
18,120, DUCROS. Sparking-plugs for internal-combustion engines.
18,184, STEYNIS & CHAUMET. Production of ozone.

Expiring Patent

The following patent expires during the current week after a life of fourteen years :—

18,215, of September 25th, 1894. **Railway Signalling Apparatus.** H. H. LAKE. (*The Hall Signal Co., U.S.A.*) A motor-operated signal with a magnetic brake. The signal rises to the danger position by gravity, after the train, by coming on to the section, has shunted the relay magnet. Before reaching the final position the signal is retarded by the magnetic brake to prevent shock. When the train leaves the section the motor operates to lower the signal. Instead of using the magnetic brake in the first instance, the motor may be driven by the signal as a generator, thus producing a braking effect.

LOCAL NOTES

ARGENTINA: *Electric Supply.*—The *Review of the River Plate* states that a Mr. Glynn has applied to the Minister of Interior for a concession for 20 years for an electric light station in Gallegos. A capital of $100,000 will be employed.

AUSTRALIA (MELBOURNE).—The *Australian Mining Standard* states that after 14 years' service, the old Thomson-Houston street lighting plant in the Council's generating station, consisting of 24 small dynamos, driven by four horizontal engines, has been displaced by two Westinghouse-Parsons turbo-generators, having a combined capacity of 650 KW.

AYR: *Electricity Accounts.*—The annual report of the Electrical Engineer, Mr. R. Marshall, shows an output of 1,375,192 units, an increase of 107,171 over the previous year. The total revenue amounted to £13,029, and the expenditure to £8,619. After meeting interest and sinking fund charges, there is a deficiency of £1,039 against a surplus of £926 last year. The deficiency is attributed to the high price of coal and the reduction in price to private consumers from 4½d. to 3½d. per unit. The Council has decided to raise the price to private consumers to 4d. per unit from November 1st.

Tramway Accounts.—The tramway accounts for the past year show capital expenditure to date of £82,030. The total revenue for the year amounted to £15,322, and the sum of £717 has been transferred to the relief of rates from the profits. The number of passengers carried was 3,660,038, which is an increase of 56,249 over the number carried last year.

BARROW-IN-FURNESS: *The New Walney Bridge.*—The electrical work in connection with the operation of the new bridge over the river Walney has now been completed, in addition to the electric lighting of the structure.

BELFAST: *Municipal Tramways Conference.*—In consequence of the Local Government Board having surcharged the expenses of the Corporation delegates to the Municipal Electrical Association this year, it has been decided not to send any official delegates to the Municipal Tramways Conference, now being held in Nottingham.

BERLIN: *Underground Railway Litigation.*—It is stated that the Berlin General Tramway Co. will apply for an injunction to prevent the construction of the projected electric underground railway from Schoneberg to the centre of Berlin, on the ground that this project infringes the company's privileges. It is recalled that the same tramway company, some time ago, successfully fought a proposal to construct an underground railway from north to south of Berlin.

BIRMINGHAM: *Tramway Extensions.*—Two memorials have been presented to the Corporation in respect of tramway extensions in the Bordesley district.

BRAY: *Electric Lighting Committee.*—Mr. T. Picton Bradshaw has resigned the chairmanship of the Electric Lighting Committee, for the reason that he could not be responsible for the working of the concern, owing to the lack of interest taken in it by other members of the Council.

BRECHIN: *Electricity Works Assessment.*—The North of Scotland Electric Light & Power Co. recently appealed against the assessment of £660 per annum upon their electric light station in Brechin. The Valuation Appeal Court, before whom the case was heard, has fixed the valuation at £400, but the company has intimated its intention of appealing against this.

BRUNSWICK: *Electric Lighting.*—The report of the Brunswick (V.) Electric Lighting Committee upon the proposal of a private syndicate to supply lighting and electric tramways to Brunswick and Coburg has been presented to the Brunswick Town Council. The report was as follows:—"That the committee recommend the Council to invite applications of tenders for an electric expert to prepare estimate, scheme, plans, and all information for installing electricity for lighting, power and other purposes throughout the city, and that Mr. Maxwell (the representative of a syndicate who had offered to install electric light in Brunswick and Coburg and electric trams for Coburg) be notified accordingly." After a good deal of discussion the report was adopted on the casting vote of the Mayor, although not all the councillors were present. On this being objected to, it was resolved to call a special meeting of the whole Council to discuss and determine the question of electric lighting.

BURY: *Gas Generating Plant.*—Mr. S. J. Watson, the Borough Electrical Engineer, has recently paid a visit to Germany to inspect some gas plant and its application to the generation of electrical energy. He has reported to his Committee on the matter.

CARDIFF: *Electric Lighting & Tramway Accounts.*—The annual statement of accounts dealing with the various trading departments of the Corporation shows that since its inception the electric lighting undertaking has paid £31,479 towards redemption of stock, and £4,400 towards loan repayments. There is also a reserve fund of £1,572, and a sinking fund of £4,107, which is being retained towards liquidation of bank overdraft. At March 31st last there was a revenue deficiency since the commencement of the undertaking of £3,338. Since its inception, the tramway undertaking has provided out of revenue £96,078 towards loan repayments, and has contributed from the reserve fund £3,857 towards outlay of a capital nature; in addition, the following funds have been accumulated out of revenue loan fund: Suspense account, £7,559; suspense account *re* mortgages, £4,448; reserve fund, £9,620; sinking fund suspense account, £7,262; and depreciation fund, £12,616. The profits on the undertaking to date amount to £12,616.

CLACTON: *Public Lighting.*—The Council has negatived a recommendation to instal public electric lighting, on the ground that this would be too expensive an experiment.

CROYDON: *Electricity Charges.*—The charge to ordinary consumers for electricity has been reduced from 5d. to 4½d. per unit.

DUMFRIES: *Electricity Supply.*—Mr. W. W. Lackie, Chief Electrical Engineer to the Glasgow Corporation, has been granted permission to advise the burgh of Dumfries as to the purchase of the electrical undertaking in that district, now operated by a company.

DUNDEE: *Trolley Omnibuses.*—In reply to an inquiry, the Board of Trade have intimated that they have no *prima facie* objection to electrical trolley omnibuses, which the Town Council have been recommended to adopt.

FELIXSTOWE: *Purchase of Electrical Undertaking.*—At the monthly meeting of the Council last week a recommendation that the undertaking of the Suffolk Electricity Supply Co. should be purchased at £8,000 was carried. We gave particulars of the purchase arrangement in our issue for September 10th.

ILFORD: *Advertising Electricity.*—The Council has adopted the method of advertising the advantages of electric power for various purposes upon the backs of the tramway tickets issued upon their tramway system. It is interesting to note that the gas company advertises on the windows of the tramcars.

IPSWICH: *Electric Lighting Accounts.*—The accounts for the year ended March 31st show a gross profit of £994, but after meeting capital charges, &c, there is a deficit of £1,789. The average price received was 3·75d. per unit against 4·18d. per unit for the previous year, but there is an increase of 2½ per cent. in the revenue per unit from power supply. The units sold for lighting show an increase of 22·34 per cent., and amounted to 317,417, and the number of consumers have increased by 25 per cent.—namely, 466—whilst the equivalent of 8-c.p. lamps connected has increased by 30 per cent.—namely, 56,420. A satisfactory feature is that the total supply for power purposes has increased by 56 per cent., the number of units being 230,712. Coal has cost £650 more than in the previous year. The total number of units sold for all purposes was 1,261,614.

Tramway Accounts.—The tramway accounts for the same period show a deficit of £1,450, which is ascribed to the wet summer, and also to the depression in trade. The total revenue amounted to £20,002, and the working expenses to £16,112, whilst interest on capital absorbed £4,109, and repayment of loans £1,805. The number of passengers carried was 4,979,253. The percentage of working expenses to receipts is 78·30 per cent.

KILMARNOCK: *Electric Lighting Accounts.*—The Electrical Engineer's report for the past year shows that the number of consumers has increased from 171 to 229, and the number of lamps connected from 15,495 to 19,680. The number of motors has increased from 23 to 34, and the horse-power from 94 to 201. The total units sold for the year has risen from 569,389 to 679,233. The total income from all sources was £5,513, and the working expenses £3,050. From the gross profit of £2,463, interest on loans, sinking fund, &c., has to be deducted, amounting to £2,840, leaving a net loss of £358, against £831 last year. The total works costs per unit sold has dropped from 1·17d. to 1·025d., and in comparison of the costs of a similar size the Electrical Engineer finds that there are only three which have lower working costs, and in each case the undertaking pays from £150 to £250 less for rates and taxes, which accounts for the difference.

Tramway Accounts.—During the past year the car miles run amounted to 306,170, against 328,829 for the previous year, whilst the passengers carried numbered 2,296,261, against 2,331,277 for the preceding year; the receipts from passengers amounted to £8,007, compared with £8,245 for the previous year. This reduction in the number of passengers is attributed to the very bad state of trade at the present time. The average fare per passenger has remained constant at 0·84d., and the manager points out that until the average fare per passenger and the total number of passengers rise very considerably, it is quite impossible to expect better financial returns. The fact that the receipts per car mile this year have risen from 6d. to 6·33d. is due to fewer miles having been run. This year for the first time there is a full year's sinking fund debited against the tramway accounts, with the result that there is a total net deficit of £1,652, which includes the sum of £610 towards the cost of obtaining the Tramways Provisional Order, and £250 for depreciation. The whole of the cars and overhead equip-

Digitized by Google

ment have been maintained during the year out of revenue, and all car wheels have been re-tyred. There is, however, a considerable amount of repair work to the permanent way still to be undertaken.

LEEDS: *Tramways Receipts.*—During the twenty-four weeks of the present financial year, the total receipts from the Corporation tramways amount to £161,474, compared with £157,586 in the corresponding period of last year.

LIVERPOOL: *Further Decrease in Tramway Receipts.*—The traffic returns for the fortnight ended September 12th show a decrease of £981 compared with the corresponding period of last year, and the passengers carried, a decrease of 195,567. The Chairman of the Tramways Committee again attributed these decreases to the bad state of trade.

LONDON: *Southwark: Electric Power Bill.*—A recommendation by the General Purposes Committee that the Council should petition against the London Electric Supply Bill, has been adopted. The Council has already petitioned against the London & District Electricity Supply Bill.

Wandsworth: New Tramways.—The London County Council and the Board of Trade have been informed that subject to certain conditions, the Borough Council will not object to the overhead trolley system of electric traction for the tramways from Hammersmith Broadway, over Putney Bridge, to Lower Richmond Road, Putney, the construction of which it is proposed to proceed with at an early date. The Borough Council has expressed the opinion that the whole width of the carriageway, including the part between the tramway rails, should be paved with wood.

MANCHESTER: *New Car Shed.*—The foundation stone of a new tramway car shed at Princess Road, Moss Side, was laid last week by the Deputy Chairman of the Tramways Committee. A piece of land 6½ acres in extent has been acquired from Lord Egerton, of which 3½ acres will be utilised for the sheds, and one acre for stabling and buildings of the permanent way department, the remainder being left available for future extensions. The sheds will accommodate 250 cars. In laying the stone Alderman Bowes stated that since the inauguration of the tramway undertaking in 1891, they had handed over in relief of rates the sum of £30,700, in addition to paying to the sinking fund £108,912, and putting aside for renewals and depreciation £382,327.

MORECAMBE: *Tramway Purchase.*—The Council has decided to take the necessary steps to obtain the consent of the Board of Trade to the purchase of the portion of the undertaking of the Morecambe Tramways Co. within the district. An offer by the Hastings Corporation to loan £7,762 for tramway purchase at 3¾ per cent. per annum, repayable in 30 years, has been accepted.

NEW SOUTH WALES: *Tramways.*—According to the *Australian Mining Standard*, the Colonial Treasurer has given the following information regarding the tramways of the city and suburbs:—"There were 54 miles of lines open in Sydney and the suburbs in 1899, and the distance covered by these services had increased to 103 miles in 1906. In 1899 the earnings were £324,101, in 1906 £795,228, and in the latter year Broken Hill and Newcastle trams added £56,256 to the earnings; while last year the total earnings were £1,011,994. The interest paid was £4 0s. 1d. per cent. in 1899, £5 1s. 7d. in 1906, and £4 18s. 8d. in 1907." In reply to a further question the following interesting particulars were supplied:—"There are three power houses within the area vested in the Sydney Harbour Trust Commissioners, situated at Napoleon Street, Circular Quay, and Cowper Wharf. Electricity is generated at these stations for the lighting of the wharfs at Woolloomooloo Bay, Circular Quay, and Darling Harbour. The cost of production is, approximately, £3,034 per annum. The Railway Department has one power-house, which is situated at Ultimo, and the cost of producing power for traction, lighting, and all other purposes for the financial year ended June 30th, was £56,304.

RAWTENSTALL: *Tramways Agreement.*—An agreement has been arrived at between the Rawtenstall and Bacup Corporations with regard to the purchase of the Rossendale tramways within the two boroughs. The price to be paid by the two Corporations to the company is roughly £33,000. The Rawtenstall Corporation are to construct the lines in the two boroughs, and to work the steam tramways until the electrification is accomplished, taking all the receipts meanwhile. The sum necessary for the purchase of the tramways in Bacup will be lent by Rawtenstall.

SMETHWICK: *Electric Lighting Provisional Order.*—The Council has finally sealed an agreement to transfer the Smethwick Electric Light Order from the Birmingham and Midland Tramways, Ltd., to the Shropshire, Worcester, and Stafford Electric Power Co.

SOUTH AFRICA (CAPE TOWN): *Electrical Finances.*—For the six months ended June 30th, the municipal electric light works at Cape Town sold 1,028,325 units, the figure for the corresponding period of last year being 939,655. The revenue for the two years was £26,519 and £24,601 respectively.

SOUTH SHIELDS: *(Rural) Overhead Wires.*—The County of Durham Electrical Power Distribution Co. has made an application to the Board of Trade for the consent to place an extra high tension transmission line between South Shields and Marsden and Whitburn Colliery Railway. The whole of the proposed line will be laid on private land, except at one spot where it crosses the public road.

WEALDSTONE: *Euston-Watford Electric Railway.*—Plans were submitted at the last meeting of the District Council by the London & North-Western Railway Co., showing bridges, &c., proposed to be constructed in connection with the Euston-Watford electric railway. Objection was raised as to one of the projected bridges, which, it was contended, would lower the width of the road, and the Surveyor and the Clerk are to interview the company's officials on the matter.

WEDNESBURY: *Electric Power Supply.*—In connection with our note last week that the Midland Electric Corporation for Power Distribution had decided not to supply any further electrical energy in Wednesbury, we understand that this is not so, but that the notice recently served upon the Council was the ordinary notice served prior to the company opening the streets to lay mains.

WEST HAM: *L.G.B. Inquiry.*—In connection with the recent Local Government Board inquiry into the application of the Council for sanction to a loan for the purposes of the electricity undertaking, when it was suggested that the Council supplied current to some of its largest consumers at less than cost price, the production of contracts showing the prices charged was requested, and although these prices were offered to be given to the Inspector privately, the officials of the Corporation declined to assent to the production of the particulars publicly. The Town Clerk has now submitted to the Electric Lighting and Tramways Committee letters from two of the customers in question, strongly objecting to the terms of their contracts being made public. In this connection the committee have considered a suggestion by the Electrical Engineer that the services of an expert should be engaged to examine the contracts with a view to supporting him in his evidence at the adjourned inquiry, and also advising the Committee on the sufficiency or otherwise of the charges made for the supply of current. They have also had before them a letter from the Town Clerk on the subject, and having considered the whole matter, they have instructed the Town Clerk and the Electrical Engineer to engage the services of an expert, and have authorised the Town Clerk to lay the whole position before the Local Government Board, should he consider it desirable.

Bulk Supply.—A bulk supply for lighting and power combined is to be given to the Lamson Paragon Works at 1¼d. per unit net.

YORK: *Light Railway Order.*—The Board of Trade have intimated that they cannot agree to the insertion in the Corporation's Light Railway Order of a clause giving power to the Corporation to sell the undertaking. The chairman of the Tramways Committee and the Town Clerk have had an interview with the Board of Trade, with the object of inducing the Board to retain the clause in question, but without result, and the clause will consequently be struck out.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—Particulars of tenders for the supply and erection of a power plant at the General Post Office, Adelaide, can be obtained from the Commonwealth Offices in London.

BEXHILL.—The Local Government Board has sanctioned the borrowing of £830 for the provision of mechanical stokers, &c.

CLACTON.—A travelling crane is to be erected in the generating station.

A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £500 for extensions to the electric light undertaking.

The recommendation of the Consulting Electrical Engineer that the Council should instal a gas-producer plant at the Electricity Works has been adopted.

EPSOM.—Estimates in connection with a scheme for the complete renewal of the battery have been prepared, and a sufficient sum is to be included in the next estimates.

FARNWORTH (BOLTON).—We understand that Messrs. Jackson, of the Plodder Lane, Farnworth, Bolton, laundry, contemplate putting down electrical plant in their laundry at an early date.

HOLYHEAD.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £3,000 for the purposes of the electrical undertaking. Of this, £1,216 are required to clear off an overdraft caused by expenditure in excess of previous loans, and £1,000 for new services.

LIVERPOOL.—The Corporation has decided to carry out several important tramway extensions.

Digitized by Google

LONDON: *London County Council.*—Tenders are invited for the supply, delivery, and erection of (*a*) six fuel economisers, each with 320 tubes with driving gear; (*b*) three electrically-driven feed pumps with capacity of 9,000 gins. per hour each; (*c*) two 5,000-kw. horizontal steam turbo-generators at a speed of 750 revs. per min. Full particulars from the Clerk to the Council, fee £2 each specification (returnable), and tenders by October 13th (see an advertisement this week).

MAIDSTONE.—A Local Government Board inquiry has been held into the application by the Corporation for sanction to borrow £18,440 for the purposes of the electricity works.

MOUNTAIN ASH.—Tenders are invited for the erection of an electrical sub-station, the supply and erection of switchgear and transforming apparatus and overhead mains. Particulars from the Surveyor, fee £1 1s., returnable, and tenders to the Clerk to the Council by October 5th.

PENDLETON.—We understand that Messrs. A. Knowles & Sons, Ltd., the well-known colliery proprietors, are contemplating putting down electrical plant at certain of their collieries in Pendleton and Pendlebury districts, near Manchester.

RADCLIFFE.—The Electrical Engineer recommends the immediate installation of an additional switchgear, together with the purchase of meters, &c.

STOKE.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £15,365 for the purpose of the electricity undertaking. During the course of the inquiry the application was amended as follows: Excess expenditure to March 31st, 1908, £1,975; additional plant, £4,450; mains, £1,600; house services, £250; extensions to Fenton, £17,555.

WATFORD.—The Urban District Council has decided that tenders be invited for the extension work necessary to meet the winter's load of 1909-10. At the last meeting of the Council, Mr. Goodrich said he believed the total cost of the work involved would be about £6,000, and would be likely to obviate the necessity of further expenditure until 1912.

Tenders are invited for the following plant: (1) 500-kw. turbo-alternator. (2) Surface condenser with steam-driven pumps. (3) Switchboard panel. (4) Economiser. (5) High-speed fan engine. Specifications, &c., from the Electrical Engineer, fee £1 returnable, and tenders to the Town Clerk by October 6th.

Miscellaneous

AUSTRALIA.—Tender forms and specifications in connection with the supply and erection of wireless telegraph installations at Launceston, Melbourne, King's Island (Bass Straits), and Flinders Island (Furneaux Group) may be obtained at the Australian Commonwealth offices in London.

Tenders are invited at the Commonwealth Offices in London by October 19th for the supply and delivery there of four complete sets of instruments (signalling and protecting) for direct duplex cable working.

BIRMINGHAM.—The Birmingham Tams and Rea District Drainage Board invite tenders for the supply and erection in their pumping station at Saltley of a three-phase induction motor of about 200-h.p. capacity for direct coupling to centrifugal pump. Full particulars from the Engineer to the Board, Tyburn, near Birmingham, and tenders by 25th inst.

Tenders are invited for the supply of 60,000 tons of coal for the generating station for delivery between October, 1908, and October, 1909. Tenders to the City Electrical Engineer by October 1st.

HARROGATE.—Tenders are invited for the supply of 26 two-arm and two four-arm fittings to carry high candle-power incandescent lamps (see advertisement this week).

ILFORD.—Tenders are invited for 1,000 tons of Welsh coal for the electricity works during the six months ended March 31st, 1909. Particulars from the Electrical Engineer, and tenders to the Clerk to the Council by October 6th.

METROPOLITAN RAILWAY CO.—Tenders are invited for stores, including the following: Electric wires and cables; electric lamps, carbons, fuses, ebonite, battery jars, zincs, &c.; steel conduits; signal and telegraph work insulators, &c. Particulars from the Secretary, to whom tenders by October 5th.

RUSSIA.—The municipality of Windau contemplates the construction of tramways; public lighting is also to be undertaken.

YORK.—Tenders will shortly be invited by the Corporation for (*a*) the construction of tramways, or (*b*) for the construction and working of tramways.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations, and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—New store, Union Castle premises, Orchard Place, Poplar. Builders, Mark Patrick & Son, 28 Westminster Bridge Road, S.W.

Additions to Clarnico Works, Carpenters Road, Poplar. J. C. Mathieson.

Additions to Salvation Army Barracks, Kirby Street, Poplar. A. Oswald.

N.E.—Factory in Sach Road, Upper Clapton. Builders, W. J. Fryer & Co., 14 Nile Street, Hoxton.

N.W.—Buildings in Tudor Place, St. Pancras. Architect, Peter Dollar, Clock House, Arundel Street, Strand, W.C.

S.E.—Addition, St. Paul's Church, Bermondsey. Architect, J. M. Kennard, 13 Railway Approach, London Bridge.

Additions to Guy's Hospital, Southwark. Architects, Wood & Ainslie, Broad Sanctuary Chambers, Westminster.

Stables, &c. (£2,000), for Greenwich Borough Council. E. J. Heward, Borough Surveyor.

New factories for Spillers & Baker, biscuit manufacturers, Jacob Street, Dockhead, S.E.

S.W.—Mission Hall, Wandsworth Bridge Road, Fulham. Architects, Z. King & Sons, 171 Victoria Street, S.W.

Additions, High School for Girls, Streatham High Road.

Additions, St. Mary's Schools, Putney. Builder, W. R. Williams, 98 High Street, Putney.

Workshops, Tooting. Swain & Selley, Furzedown Farm, Streatham.

Addition to Convent of St. Andrew, Streatham. Architect, E. Goldie, 31 Upper Phillimore Place, Kensington.

Alterations and additions to Southfields Club and Institute, Standen Road.

PROVINCES.

AVEBURY (WILTS).—House (£2,570). Architect, Harold Brakspear, Corsham.

BERKHAMSTED.—Adaptation of premises, High Street, for Council offices (£1,000). Surveyor, E. H. Adey, District Council.

BLACKPOOL.—Central Public Library. T. Loftos, Town Clerk (architect not yet appointed).

BOLTON.—Three Branch Libraries (£15,000). Samuel Parker, Town Clerk, Bolton.

BOXMOOR.—House (£2,150). Architect, Albert Bullock, 43 Chancery Lane, W.C

BRADFORD.—Addition to Assembly Rooms, Manchester Road. Wm. Dracup.

Addition to Institute, Clayton Road. Vicar and Wardens, St. Wilfred's, Church.

School, Back Lane, Buttershaw. Bradford Education Committee.

CARLISLE.—Turkish Baths (£2,290). Engineer and Surveyor, H. C. Marks, 36 Fisher Street, Carlisle.

CHELTENHAM.—Alterations and additions, St. Mark's Schools, Alstone Lane. The Managers.

Two new laundries, Fairfield Walk. F. E. Jenkins.

Two new laundries, Asquith Road. T. W. Smith.

CORNWALL.—New County Offices, Christopher L. Cowlard, Clerk to County Council, Bodmin.

CROYDON.—Additions to workhouse, and erection of new children's home. Architect, Henry Berney, 104 George Street, Croydon.

Extension (£7,500), Croydon Isolation Hospital. R. M. Chart, Surveyor, Croydon Rural District Council.

New Street, Roke Lodge, Croydon. J. P. Oldaker, Wilburn Lodge, Purley.

FINCHLEY.—34 houses and shops. Builder, G. Ball, 144 Fortress Road, N.W.

Five houses. Surveyor, F. E. Halford, 8 Southampton Street, Bloomsbury, W.C.

Five houses. Builders, Halliday & Son, 74-76 High Street, North Finchley.

Two houses. Surveyor, A. W. Wheeler, Woodside Park Station, North Finchley.

Four houses. Finchley Co-partnership Society, Ltd.

Additions to convent, East End Road. Rev. Mother Superior.

Three houses, Granville Road, for Northern Suburban Land Co.

GLOUCESTERSHIRE.—School at Sydbrook (£3,430), for County Council. Architects, Medland & Pryer, 15 Clarence Street, Gloucester.

GODREAMAN.—New Boys' School (£9,387) for Aberdare Urban District Council Education Committee. Builder, J. Morgan & Son, Ltd., Aberdare.

GREENFORD (MIDDLESEX).—Power house in connection with new works at Perivale of Purex Lead Co.

GUERNSEY.—New asylum (£16,000). Architect, G. T. Hine & Co., 35 Parliament Street, S.W.

ILFORD.—Additions, 1 to 97, and 18 to 96, Vaughan Gardens. Architect, G. Verlyck, Adelaide Chambers.

Six shops and house premises. Architect, A. W. Hudson, 87 Finsbury Pavement, E.C.

Unitarian Church, High Road.

Motor house and store, The Laurels, Aldborough Road. Builder and contractor, G. Sharpe, Gibbins Road.

Six houses, Clarissa Road. Surveyor, P. G. Ashton, Station Approach.

Store, Newbury Gardens. Architect, E. T. Dunn, 7 Roden Street.

LLANDUDNO.—New library. Alf. Conolly, Town Clerk.

Digitized by Google

ROTHERHAM.—Alterations and extensions at Grammar School (£5,120). Architect, J. E. Knight, College Street, Rotherham.

SALFORD.—The Education Committee require tenders for the electric wiring in the Halton Bank Council School, Pendleton. Specification from the Borough Electrical Engineer, Frederick Road, Pendleton (fee £1 1s. returnable), and tenders by October 5th.

SHEERNESS.—Masonic Hall (£1,780). Architect, Ernest J. Hammond, Gillingham, Kent. Builder, West Bros., Rochester.

SMETHWICK.—Ten houses, Vicarage Road. Architect, T. Richards & Son, Lichfield Street, Wolverhampton.

STOKE NEWINGTON.—Adapting 36 and 38, Milton Road to public slipper baths for Borough Council. Surveyor, W. F. Loveday, Town Hall, Milton Road, N.

SWANSEA.—Cottage Exhibition. Town Clerk.

Proposed hall for Territorial Forces (£20,000).

TIPTON.—Offices for Urban District Council. Engineer and Surveyor, W. H. Jukes, Public Offices, Tipton.

WATFORD.—Additions, Silverdale Laundry. Builder, W. Judge, 14 The Parade, High Street, Watford.

New offices for London & North-Western Railway Co., Euston Station, N.W.

Vagrant accommodation, Union Workhouse, Watford Board of Guardians.

New Vicarage, Mildred Avenue, Watford. Rev. W. H. Littlebury.

WEST HAM.—Alterations, Nurses' Home, Custom House. Builder, E. Beasley, 295 Victoria Dock Road, E.

Additions (packing warehouse and dining hall) to Co-operative Wholesale Society's premises, Silvertown.

Petrol store at 124 Romford Road, Stratford, for R. B. Godfree.

Addition (pattern shop) to premises at Silvertown of India Rubber, Gutta Percha, and Telegraph Works Co., Ltd.

WREXHAM.—Church extension. Architects, Prothero, Phillott, & Barnard, 13 Promenade, Cheltenham.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Hampden Shire Council (Victoria) has accepted the following tenders: Messrs. Hornsby & Co., Melbourne, electric lighting and suction gas plant, £1,128; A. H. Wood, Melbourne, dynamo and electric appliances, £1,575; British Insulated & Helsby Cables, Melbourne, cables and wires, £350.

The Electric Supply Committee of the City of Melbourne has accepted the tender of Messrs. Davy Shepherd & Co. for the supply of a water meter for the new boilers.

The South Australian Postmaster-General's department has accepted the following tenders, says the *Australian Mining Standard*: For telephones, switchboards, and cable, 300 telephones, magneto, wall sets, at 52s. 10d. each—J. Bartram & Son, King-street, Melbourne; three switchboards, each for 100 metallic circuit lines, at £52 6s. 2d. each; 5½ miles cable, 208 pair, lead covered (12½ lb. conductors), at £486 per mile; 5 miles cable, 13 pair, lead covered (20 lb. conductors), at £81 per mile; 900 yards cable, 104 pair, light lead covered, for the sum of £184 12s.—British Insulated & Helsby Cables, Ltd., Collins Street, Melbourne; 3½ miles cable, 156 pair, lead covered (12½ lb. conductors), at £389 per mile; 3¼ miles cable, 104 pair, lead covered (12½ lb. conductors), at £284 10s. per mile —The Western Electric Co. (Australia), Ltd., Pitt Street, Sydney; 2 miles cable, 78 pair, lead covered (12½ lb. conductors), at £229 per mile; 4 miles cable, 52 pair, lead covered (12½ lb. conductors), at £175 per mile; 2 miles cable, 26 pair, lead covered (20 lb. conductors), on ¼-mile drums, at £132 per mile —W. T. Henley's Telegraph Works Co., Ltd., Flinders-lane, Melbourne.

FINCHLEY.—The District Council has accepted the tender of Whipp & Bourne, at £336 10s., for the switchgear extensions.

HECKMONDWIKE.—The tender of Messrs. W. T. Henley's Telegraph Works Co., Ltd., for the supply and laying of cable in connection with the Co-operative Wholesale Society's premises, has been accepted.

LONDON: *Hammersmith.*—The Electricity and Lighting Committee of the Borough Council has accepted the tender of the Improved Wood Pavement Co., Ltd., at £42, for oak block flooring required for a new switchboard.

The Electrical Engineer has presented a report with regard to the contract placed with the British Thomson-Houston Co., in July, 1904, for a Curtis turbine, for £9,145. The machine was first put into commission in September, 1906, and has been in almost constant use since January, 1907, having run 9,118 nours, and generated 6,546,210 units during that time. In one or two details, however, the Engineer says that it is not quite in accordance with the specification. Since the machine was designed, adds the Engineer, improvements have been made in these alternators, and the company are now in a position to offer increased output from this machine if advantage is taken of the additional experience when the machine is being reconstructed. The Borough Council Electricity and Lighting Committee has resolved that the offer of the British Thomson-Houston Co. to increase the output of the Curtis turbine from 1,500 kw. to 2,000 kw., when they are rebuilding the machine, for £550, and to supply the spare parts required for £136 be accepted.

MANCHESTER.—Messrs. A. Reyrolle & Co., have received the contract for two years' supply, from the Corporation, for semi-enclosed and totally-enclosed motor starters of the following sizes:—15, 20, and 30 h.p. This contract is for their well-known "Wait on the first stop until the motor starts" type.

ORIENT STEAM NAVIGATION CO.—The contract for the electrical equipment of three of the five new liners of this company now under construction has been placed with W. C. Martin & Co., of Glasgow. It is stated that the installation will be on the lines of that fitted by the same company on the Cunard liner *Mauretania*, and will comprise about 2,000 lights, ventilating fans, heating apparatus, telephones, and searchlights for navigating the Suez Canal at night.

RICHMOND (DUBLIN).—In competition with an offer from the local gas company, the Dublin Corporation have put in a tender for the electric lighting of the District Lunatic Asylum. The matter has been referred to a sub-committee, the opinion being expressed that if there is no great difference between the two tenders, preference shall be given to the Corporation.

TASMANIA.—The following tenders have been received by the Postmaster-General's department:—200 common battery wall telephones, International Electric Co., London, £417 10s.; extensions to common battery switchboard at Hobart, Western Electric Co., £2,186; 800 double-pole receivers and cords, The North Electric Co., Cleveland, U.S.A., £196.

WATFORD.—The Council has accepted the following tenders:—Condensing plant, the Worthington Pump Co., £620; extension of cooling water supply, L. R. Ensor, £696; superheaters to two boilers, Babcock & Wilcox, £260. It has been found necessary also to lay a new suction and new delivery pipe for the new condenser, at an estimated cost of £180. For new links to a stoker the tender of Babcock & Wilcox, at £38, has been accepted, and that of Clifford & Gough, at £34 19s., for re-arrangement of stores, additional office accommodation, and new windows in boiler house. The Council has accepted the tender of Stephenson, Clarke & Co., for the supply until March 31st, 1909, of Gedling top hard nuts at 15s. per ton delivered.

WIMBLEDON.—An order has been placed with the General Electric Co. for 1,300 high-voltage Osram lamps for street lighting.

COMPANIES' MEETINGS AND REPORTS

ANGLO-ARGENTINE TRAMWAYS CO.—Meetings of shareholders of the various classes of this company were held last week, when the following resolution was passed:—"That, notwithstanding anything contained in the resolution passed at the general meeting of the company held on July 26th, 1907, the directors be, and they are hereby authorised to apply the company's debentures or debenture stock which may be issued under the powers conferred by such resolution or the proceeds thereof, not only for acquiring the debentures or debenture stock of any company or companies carrying on any other tramway undertaking or undertakings in the City of Buenos Ayres, the interest on which shall not at the date of such acquisition be in arrear, but also to the redemption of the debenture stocks of the Buenos Ayres Electric Tramways Co. (1901), Ltd., and of the debentures or debenture stock (the interest on which shall not at the date of acquisition or redemption be in arrear) of any other company carrying on a tramway undertaking in the City of Buenos Ayres or its vicinity in which this company may be or shall become interested, and to the repayment of any loan which may be made to this company for the purpose of acquiring or redeeming any such debentures or debenture stock."

DICK, KERR & CO.—The report for the year ended June 30th shows that the profits earned during the twelve months amounted to £59,558. Out of this has had to be paid debenture interest and trustees' fees, and there has been reserved the sum required to provide for the premium payable on the redemption of the present debenture stock. These items absorb £12,831, leaving a balance of £46,726, to which must be added the profits brought forward from last year, viz., £79,140, making a total of £125,867, available for distribution as follows:—Dividend of 6 per cent. per annum on the preference shares, £18,300; dividend of 10 per cent. on the ordinary shares, less income

Digitized by Google

tax, £26,600; the balance of £81,566 being carried forward. The dividend on the preference shares will be paid on October 1st, 1908, as usual, and the dividend recommended on the ordinary shares will be paid when approved by the shareholders. In view of the continued severe competition in all departments, the directors consider the result of the year's trading not altogether unsatisfactory. Mr. R. H. Prestwich and Mr. Thos. D. Lingard retire from the Board, but offer themselves for re-election. The meeting is on Tuesday.

DIRECT WEST INDIA CABLE CO. The report for the year to June 30th, shows a net profit of £6,149, against £2,090 for the previous year. The difference between the two sums is accounted for by interruptions last year owing to the earthquake, when traffic was suspended for about nine weeks. An interim dividend of 3 per cent. has already been paid, and it is proposed to make a further equal demand free of income tax, leaving £4,349 to be carried forward. This increases the amount to the credit of revenue account to £33,495. Debentures have been paid off during the year to the amount of £6,100, leaving £50,900 outstanding. At the meeting on Thursday the report and accounts were adopted.

DUNDEE BROUGHTY FERRY & DISTRICT TRAMWAY CO.—At the annual meeting on Thursday, the report and accounts given in our issue for September 10th were adopted. The Chairman pointed out that during the year they had had nine months of very bad weather, yet their receipts were £200 better than the previous year. At the same time, the Board were quite unable to say when it was likely that a dividend would be paid upon the ordinary shares.

HALIFAX & BERMUDAS CABLE CO.—The accounts for the year to June 30th, show a net profit of £3,095, against £3,182 for the previous year. An interim dividend of 2½ per cent has already been paid, and after making a further equal payment, free of income tax, the sum of £595 is carried forward. The amount outstanding to the credit of revenue account is thus increased to £17,192. Debentures were paid off during the year to the amount of £9,300, leaving £19,600 outstanding. At the meeting on Thursday the report and accounts were adopted.

UNITED ELECTRIC CAR CO.—At the annual meeting last week, the report and accounts given in our last issue were adopted. The Deputy Chairman, Mr. R. H. Prestwich, who presided, stated that it was with much regret that the directors found themselves unable to recommend a dividend upon the ordinary shares. Those who were present at the previous meeting would remember that a fall in the profits had been foreshadowed, owing to the stagnation in electric traction, which was affecting all car builders as well as electrical equipment manufacturers. He was sorry to say that instead of improving, matters had got worse, with the result that their output was less than one-half than what it was for the preceding year. Fortunately there has been a considerable reduction in the expenses without adversely affecting the interests of the company. With regard to the future, he regretted he could not say there were any signs of immediate improvement. A shareholder suggested that instead of transferring the amount shown by the accounts to the reserve fund, this should be dealt with to enable a dividend of 2½ per cent. to be declared on the ordinary shares, but this resolution was ruled out of order.

Tramcar Accidents.—Early on Friday morning the driver of a tramcar in Huddersfield lost control of it, and the car dashed down a hill at a great speed, colliding with another tramcar at the bottom. Both vehicles were thrown off the rails and badly damaged, and the driver of the runaway car had his left ankle broken. No passengers were injured.

On Sunday a London County Council tramcar in Old Street ran into two others which were standing at the stopping place near the corner of City Road, owing, it is said, to the failure of the magnetic brakes to pull the car up in time. At this particular spot a speed of sixteen miles per hour is permitted by the Board of Trade regulations. All the cars carried passengers, and nine had to be taken to the hospital with various injuries, but only one was detained.

A collision took place between two tramcars belonging to the Bournemouth Corporation at Tuckton Bridge, near Christchurch, on Thursday. The accident occurred upon a loop line, but nobody was injured.

Telegraph Traffic.—The Lagos-Kotonon cable was restored on the 15th inst., while on the following day communication between Pontianac and Saigon became interrupted. The cables between St. Vincent and Barbados, which failed on the 15th inst., were restored on the 16th inst. The cable connecting Sitia and Rhodes failed on the 17th inst. This was followed by the breaking of the cable between the Dardanelles and Constantinople on the 20th. As the land lines between Constantinople and Smyrna are overloaded, telegrams via the Tenedos cable are subject to delay. The lines of the Neva European Telegraph Co. were down between Djoulfa and Tauris on the 21st inst., but were repaired on the following day. The French Cable Co. have also succeeded in repairing the cable between Paramaribo and Cayenne, which was again open for traffic on the 21st inst.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. Nelson, of the firm of Messrs. Merz and McLellan, has been appointed to the newly-created post of H.M. Electrical Inspector of Mines. Mr. Nelson has incidently been appointed an Inspector for the purpose of the Metalliferous Mines Regulation Acts, 1872 and 1875, and of the Quarries Act, 1894, and has further been appointed an Inspector of Factories for the purposes of the Factory and Workshops Act, 1901.

The Rangoon Electric & Tramway Supply Co. require an experienced jointer, accustomed to high tension work. Apply, 14 Dale Street, Liverpool.

The Handsworth Council have adopted the recommendation of the Electricity Committee to increase the salary of the Electrical Engineer, Mr. F. A. Nixon, from £350 to £400 per annum.

The Electricity and Street Lighting Committee of Bermondsey Borough Council received 126 applications for the post of engineer-in-charge to fill the vacancy caused by the promotion of Mr. Hogarth, at a salary of £110 per annum, without pension. Mr. Cragg, of Putney, has been appointed to the position.

Mr. J. Milton has resigned his appointment as shift engineer at the Battersea Borough Council electricity works, to take up an appointment as chief assistant engineer to the Wycombe (Borough) Electric Light & Power Co., Ltd.—The Battersea Lighting Committee has resolved that Mr. W. H. Healy, at present engaged as draughtsman at the central station, be appointed shift engineer on probation for three months, at a salary of £120 per annum, and that the Electrical Engineer be authorised to engage a person temporarily to take the place of Mr. Healy.

Mr. G. Shaw Scott, M.Sc., of Sutton Coldfield, has been appointed permanent Secretary to the Institute of Metals.
